Volume 76, Number 1
Spring 1989

Annals of the
Missouri Botanical Garden

The Annals, published quarterly, contains papers, primarily in systematic botany, contributed from the Missouri Botanical Garden, St. Louis. Papers originating outside the Garden will also be accepted. Authors should write the Editor for information concerning arrangements for publishing in the ANNALS. Instructions to Authors are printed in the back of the last issue of each volume.

TESSMANNIANTHUS, AN ARBORESCENT GENUS OF MELASTOMATACEAE NEW TO PANAMA[1]

Frank Almeda[2]

ABSTRACT

Recent collecting activity in montane cloud forests of western and central Panama has led to the discovery of two new species of *Tessmannianthus*, a little-known genus of trees previously recorded from Colombia, Ecuador, and Peru. *Tessmannianthus carinatus* and *T. gordonii* are described, illustrated, compared, and contrasted with similar species. A key to the new taxa and a synoptic history of the genus are also provided.

In a paper describing new Peruvian flowering plants collected by the late Günther Tessmann, Markgraf (1927) proposed the new genus and species *Tessmannianthus heterostemon*, to accommodate one of the tallest known trees (30–45 m) among neotropical Melastomataceae. Markgraf's circumscription of *Tessmannianthus* emphasized its unique androecial characters. The connectives on the larger set of dimorphic stamens are modified dorsally into biauriculate, ventrally upturned appendages. The smaller anther sacs are longitudinally bifurcate distally and have connectives that are prolonged dorsally at the base into bilobed or deflexed, bifid appendages. These characters, together with the pentamerous flowers, trilocular capsular fruits, and prevailingly lepidote indument, define *Tessmannianthus* as a natural alliance worthy of generic rank.

For nearly fifty years *Tessmannianthus* was thought to be a monotypic genus. Wurdack (1975) described *T. cenepensis* and transferred the enigmatic *Miconia calcarata* Gleason to *Tessmannianthus*, enlarging the genus to three species and extending its range from Peru northward to Colombia.

Because of its arborescent habit, rainy season flowering, and evidently limited number of individuals in any one population, *Tessmannianthus* has

[1] I thank John J. Wurdack for sharing information about *Tessmannianthus*, Gordon McPherson for returning to collecting localities to gather flowering material, and curators of the following herbaria who sent specimens as gifts or loans: F, MO, NY, US.

[2] Department of Botany, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-9961, U.S.A.

escaped the attention of most collectors. Each of the species is known from fewer than six collections, and open flowers of *T. cenepensis* and mature seeds of *T. heterostemon* remain unknown.

The discriminating collecting efforts of Gordon McPherson in Panama have yielded the first collections of the two new species described here. Among the six merianioid genera of Melastomataceae now known from Panama (Gleason, 1958; D'Arcy, 1987), *Tessmannianthus* is likely to be confused only with *Graffenrieda*. The latter is distinguished by a calyptriform or irregularly rupturing calyx, dorsally arcuate stamens, and anther connectives modified into acute dorso-basal spurs. The Panamanian species of *Tessmannianthus* do not appear to be closely related to one another. They are, nevertheless, readily separated from all other Central American melastomes by the following characters: the small (4–7.5 × 2–6 mm) clawed petals are retrorsely erose-ciliolate; the larger ventrally arcuate anthers open by a pair of ventrally inclined confluent pores; and each of the bifurcate anther sacs in the smaller stamens opens by a dorsally inclined pore.

KEY TO *TESSMANNIANTHUS* IN PANAMA

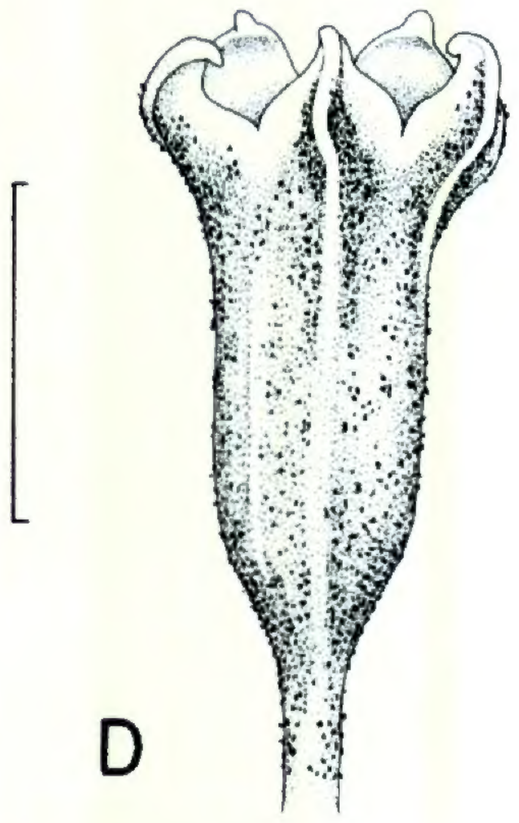
1a. Upper leaf surfaces sulcate, the elevated nerves on lower leaf surfaces moderately covered with a caducous mixture of shaggy-dendritic (pinoid) and lepidote hairs; hypanthia (at anthesis) 7–8 mm long to the torus; calyx lobes beset with a carinate keel that forms an incurved clawlike apical tooth; petals distally puberulent abaxially; larger anthers 9.5–10 mm long ... 1. *T. carinatus*

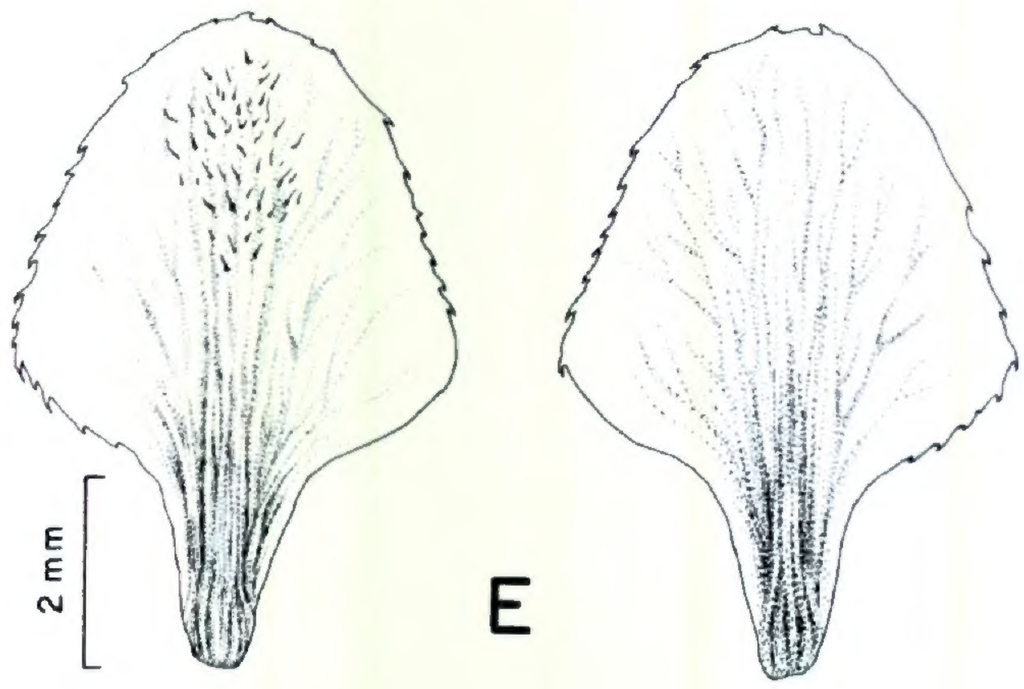
1b. Upper leaf surfaces essentially flat, the elevated nerves on lower leaf surfaces moderately to sparingly covered only with lepidote hairs; hypanthia (at anthesis) 3(–3.5) mm long to the torus; calyx lobes beset with an inconspicuous blunt subapical tooth; petals glabrous abaxially; larger anthers 4.5 mm long ..... 2. *T. gordonii*

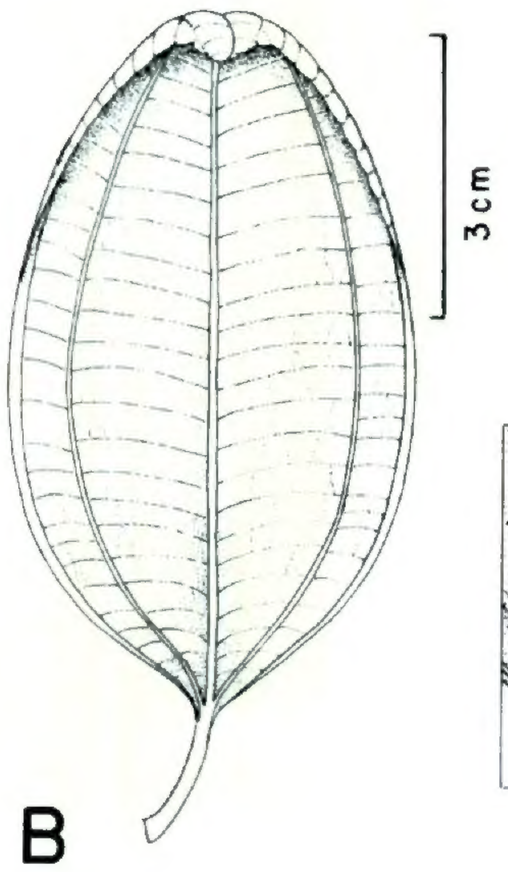
Tessmannianthus carinatus Almeda, sp. nov. TYPE: Panama. Panamá: Cerro Jefe region, ca. 9°15′N, 79°30′W, forest near summit, ca. 850 m, 24 Aug. 1986 (fl), *McPherson 9980* (holotype, CAS; isotypes, MO, PMA, not seen). Figure 1.

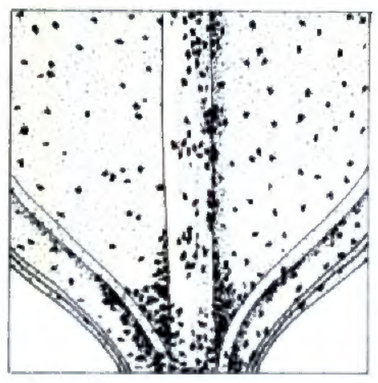
Ramuli primum quadrangulati demum teretes sicut folia novella foliorum subtus venae primariae inflorescentiaque dense vel modice pilis pinoideis ca. 0.5 mm longis et squamis lepidotis modice intermixtis. Petioli 0.5–1.4 cm longi; lamina 4.3–8.5 × 1.7–4.4 cm elliptica vel elliptico-ovata apice breviter (2–3 mm) gradatimque acuminato basi obtusa, 5-nervata (pari inframarginali tenui neglecto) nervis secundariis ca. 2.5–4 mm inter se distantibus subtus elevatis, coriacea et integra. Panicula 3–5.5 cm longa multiflora; flores 5(–6)-meri, pedicellis (ad anthesim) 3–6 mm longis. Hypanthium (ad torum) 7–8 mm longum; calycis tubus 1.5 mm longus, lobis 2.5 × 3 mm late ovatis, dentibus exterioribus callosis acutis ca. 1 mm eminentibus. Petala 7–7.5 × 5.5–6 mm obovato-suborbicularia ca. 2–2.5 mm unguiculata extus apicaliter modice puberula. Stamina dimorphica glabra; antherae ad basim in staminibus maioribus et staminibus minoribus biauriculatae. Ovarium triloculare et ca. ⅔ inferum. Fructus maturus ignotus.

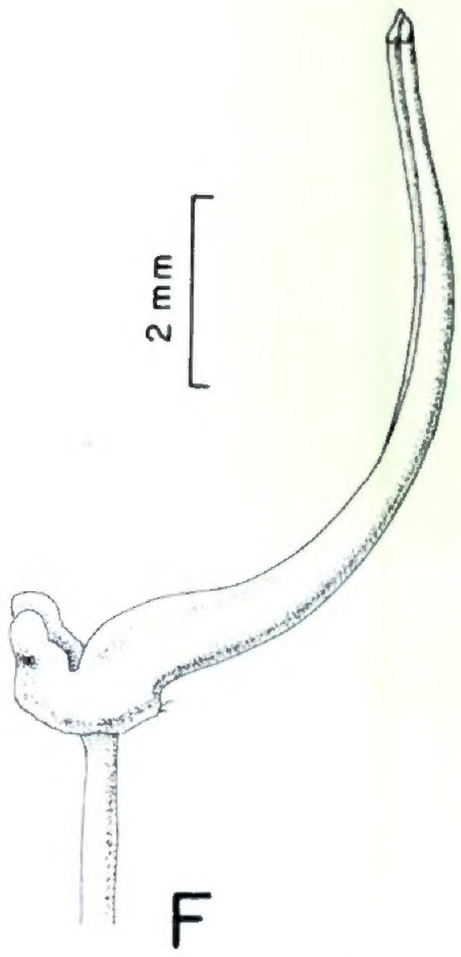
Trees to 11 m tall. Older cauline internodes terete and glabrous; the subquadrangular distal branchlets, vegetative buds, and inflorescences moderately to densely covered with a mixture of dark brown shaggy-dendritic and irregularly-shaped lepidote hairs. Leaves of a pair essentially equal in size; petioles 0.5–1.4 cm long; blades coriaceous, 4.3–8.5 cm long, 1.7–4.4 cm wide, elliptic to elliptic-ovate, apex gradually acuminate with a short acumen (2–3 mm), this obtuse to broadly rounded and curved downward, base obtuse, margin entire and revolute distally, 5-nerved abaxially, the outermost pair of primaries often inconspicuous and concealed by the revolute margins when dry, the transverse secondaries elevated like the primaries and spaced 2.5–4 mm apart at the widest portion of the blade, glabrous and sulcate above at maturity, covered with a mixture of dendritic and lepidote hairs on the elevated primaries below, otherwise moderately beset only with lepidote hairs. Inflorescence a terminal multiflowered panicle 3–5.5 cm long; bracteoles paired, early caducous, linear-oblong to narrowly obovate, 1.5–5 mm long, 0.5–2 mm wide, margin entire, glabrate above, moderately lepidote below. Pedicels 3–6 mm long, densely lepidote. Hypanthia (at anthesis) cylindric, 7–8 mm long to the torus, moderately to copiously lepidote. Calyx tube 1.5 mm long on flowering hypanthia; calyx lobes reportedly white, ovate but appearing deltoid abaxially because of the carinate clawlike tooth (ca. 1 mm high) at the incurved summit, 2.5 mm long (excluding tooth) and 3 mm wide basally between sinuses, the margins entire. Petals 5(–6), reportedly pale pink, 7–7.5 mm long, 5.5–6 mm wide, obovate-suborbicular, rounded apically, abruptly tapering to a basal claw 2–2.5 mm long, glabrous adaxially but puberulent distally on the abaxial surface, the margin retrorsely erose-ciliolate. Stamens 10(–12), strongly dimorphic with larger stamens inserted on the torus opposite the calyx lobes and smaller ones inserted opposite the petals; filaments somewhat declinate, complanate and glabrous; anthers yellow and 2-celled. Larger stamens: filaments 6.5–7 mm long; anthers geniculate at the filament insertion, 9.5–10 mm long and 0.5 mm wide, subulate, ventrally arcuate and channeled between the thecae, opening by 2 ven-











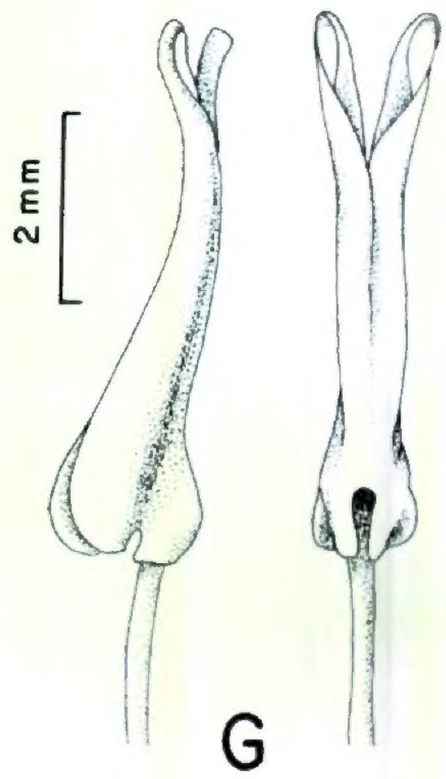


FIGURE 1. *Tessmannianthus carinatus.*—A. Habit.—B. Representative leaf.—C. Base of leaf blade (abaxial surface) with enlarged lepidote hairs.—D. Hypanthium (at anthesis); petals, stamens, and style removed.—E. Petals, abaxial surface (left), adaxial surface (right).—F. Larger stamens (lateral view).—G. Smaller stamens, lateral view (left), dorsal view (right). Drawn by Ellen del Valle from the holotype.

trally inclined confluent pores; connective thickened dorsally and prolonged at the minutely puberulent base into a ventrally upturned biauriculate appendage, with each lobe 1–1.5 mm long and 0.5 mm wide. Smaller stamens; filaments 5.5–6 mm long; anthers 6 mm long and 0.5 mm wide basally, linear-oblong, erect to somewhat incurved distally with the 2 thecae of each anther diverging from one another, each theca opening by a dorsally inclined pore; connective thickened dorsally and prolonged at the base just above the filament insertion into a deflexed, deeply bifid appendage 0.5

mm long having each lobe caudiform in dorsal and ventral view. Ovary (at anthesis) ca. ⅔ inferior, 3-celled, oblong, glabrous at the apex. Style 7.5–8 mm long, 0.5–1 mm wide, glabrous, somewhat declinate and slightly incurved distally; stigma round to subtruncate. Mature capsule and seeds not seen.

Distribution. Known only from the summit area of Cerro Jefe in central Panama at about 850 m, where the new species is evidently an uncommon member of the low cloud forest vegetation. It grows with but appears to be greatly outnumbered by the vegetatively similar Cerro Jefe race of *Conostegia montana* (Sw.) D. Don ex DC.

Tessmannianthus carinatus differs from other members of the genus in characters of the foliage, indument, and calyx lobes. The leaves of this species are leathery and sulcate, with a rounded terminal acumen that is turned downward. The indument on young branches, inflorescences, and the elevated primary nerves on lower leaf surfaces consists of a mixture of appressed lepidote hairs and spreading dendritic or pinoid hairs. The former hair type is found in all other members of the genus; the latter is unique to *T. carinatus*. The specific epithet draws attention to the distinctive calyx morphology. Each lobe is beset with a carinate abaxial keel that forms an apically incurved clawlike tooth (Fig. 1D).

Tessmannianthus carinatus appears to be without close relatives. Its leathery leaves are vaguely reminiscent of *T. heterostemon*, which differs markedly in having larger (9–20.5 × 6.4–13.5 cm) apically rounded obovate blades, shorter hypanthia (3–4 mm) with minute caducous exterior calyx teeth, and elliptic-oblong, papillate petals.

Tessmannianthus gordonii Almeda, sp. nov.
TYPE: Panama. Chiriquí: Fortuna Dam watershed, above Río Hornito, 08°45′N, 82°15′W, 1,250 m, 1 July 1987 (fl), *McPherson 11161* (holotype, CAS; isotypes, AAU, BM, COL, CR, DUKE, EAP, F, K, LE, MEXU, MO, NY, P, PMA, QCA, TEX, U, US, VEN, not seen). Figure 2.

Ramuli primum quadrangulati demum teretes sicut petioli foliorum subtus venae primariae inflorescentiaque squamis lepidotis demum caducis sparsiuscule induti. Petioli 0.6–1.3 cm longi; lamina 4.4–6.8 × 2.1–2.9 cm elliptica apice acuminato, basi acuta vel obtusa, 3–5-nervata vel 3–5-plinervata (pari tenui marginali neglecto) firme membranacea et integra. Panicula 2.5–3.5 cm longa multiflora; flores 5-meri, pedicellis (ad anthesim) 2–3.5 mm longis. Hypanthium (ad torum) 3(–3.5) mm longum; calycis tubus ca. 0.5 mm longus, lobis 1 × 2 mm ovatis, dentibus exterioribus crassis 0.5 mm eminentibus. Petala glabra 4–4.5 × 2–2.5 mm elliptico-oblonga ca. 0.5–1 mm unguiculata. Stamina dimorphica glabra; antherae ad basim in staminibus maioribus et staminibus minoribus distincte biappendiculatae. Ovarium triloculare; capsula ca. 5–6 mm longa; semina numerosa 2–2.5 mm longa anguste pyramidata.

Trees 9–16 m tall. Older cauline internodes terete and glabrous; the quadrangular distal branchlets, lower leaf surfaces, and inflorescences beset with a moderate covering of caducous lepidote hairs. Leaves of a pair essentially equal in size; petioles 0.6–1.3 cm long; blades firmly membranaceous, 4.4–6.8 cm long, 2.1–2.9 cm wide, elliptic, apex acuminate, base acute to obtuse, margin entire, 3–5-nerved or 3–5-plinerved abaxially with the innermost pair of primary nerves elevated and diverging from the median nerve in opposite fashion about 2–4 mm above the blade base, the outermost pair of primaries mostly depressed and inconspicuous, essentially glabrous above at maturity, sparingly to moderately beset with brown lepidote hairs below. Inflorescence a terminal multiflowered panicle 2.5–3.5 cm long with ultimate branchlets terminating in umbelliform clusters; bracteoles paired, sessile, persistent to tardily deciduous on the infructescence, ovate to oblong-ovate, rounded apically, 0.5–3 mm long, 0.5–2 mm wide, margin entire, glabrous on the concave upper surface, moderately to copiously lepidote to glabrate on the lower surface. Pedicels 2–3.5 mm long, sparingly lepidote to glabrate. Hypanthia (at anthesis) subcylindric to narrowly campanulate, 3 (–3.5) mm long to the torus, glabrous or sparingly lepidote toward the base but typically glabrous at maturity. Calyx tube ca. 0.5 mm long on fruiting hypanthia; calyx lobes broadly ovate but appearing bluntly deltoid because of the terminal tooth (to 0.5 mm long) on the glabrous abaxial surface, 1 mm long, 2 mm wide basally between sinuses, the margins entire and somewhat incurved apically. Petals 5, glabrous, reportedly pink-white, elliptic-oblong to narrowly obovate, rounded to shallowly and irregularly lobed apically, gradually tapering to a short (0.5–1 mm) basal claw, 4–4.5 mm long, 2–2.5 mm wide, retrorsely erose-ciliolate. Stamens 10, strongly dimorphic with larger stamens inserted on the torus opposite the calyx lobes and smaller ones inserted opposite the petals; filaments somewhat declinate, complanate and glabrous; anthers yellow, 2-celled. Larger stamens: filaments 5 mm long; anthers geniculate at the filament insertion, 4.5 mm long, 0.5 mm wide, linear-oblong, arcuate and channeled ventrally between the thecae, opening by 2 ventrally inclined confluent pores; connective thickened dorsally and prolonged at the

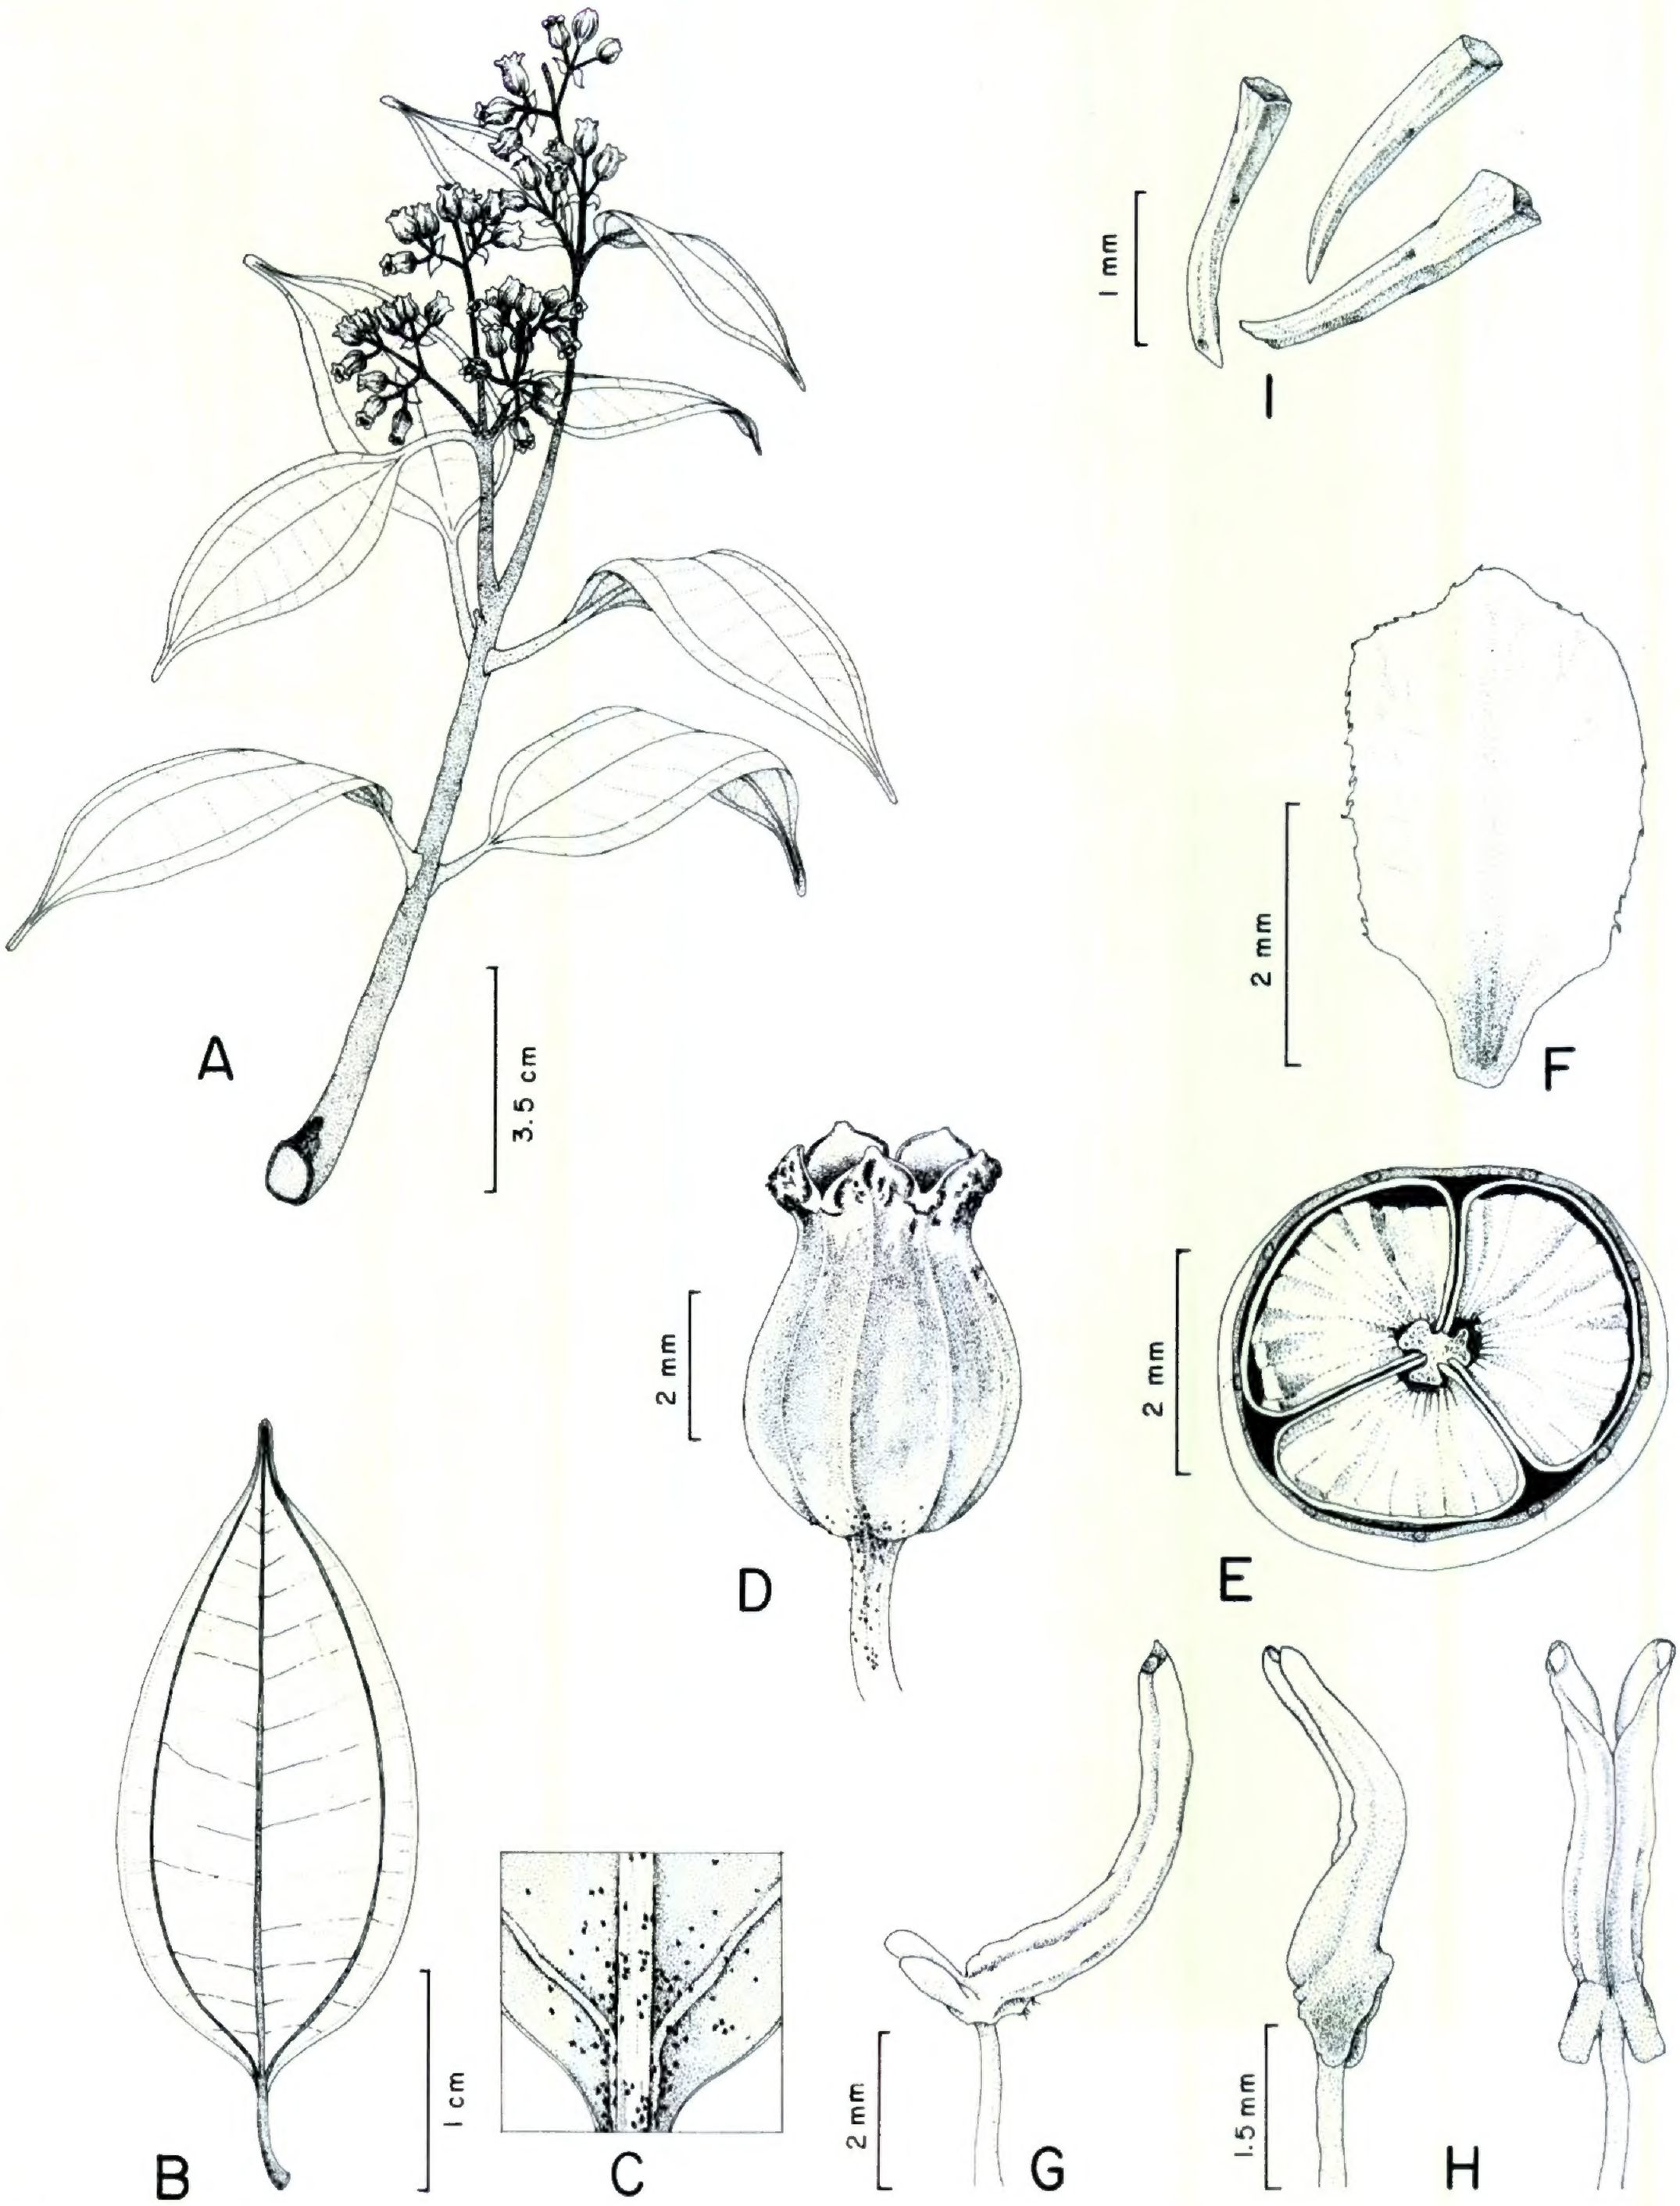

FIGURE 2. *Tessmannianthus gordonii.*—A. Habit. —B. Representative leaf (abaxial surface).—C. Base of leaf blade (abaxial surface) with enlarged lepidote hairs.—D. Hypanthium (in fruit).—E. Cross section of capsule and enveloping hypanthium.—F. Petal (abaxial surface).—G. Larger stamens (lateral view).—H. Smaller stamens, lateral view (left), dorsal view (right).—I. Seeds. minutely puberulent base into a ventrally upturned deeply bifid appendage, with each lobe 1 mm long and 0.5 mm wide. Smaller stamens: filaments 4–5 mm long; anthers 2.5–3 mm long, 0.5 mm wide basally, linear-oblong, erect to somewhat incurved distally where the 2 thecae diverge from one another, each theca opening by a dorsally inclined pore; connective thickened dorsally and prolonged

basally into a deflexed biauriculate skirtlike appendage (0.5–0.75 mm long), with each of its lobes tail-like in ventral and dorsal view and obdeltoid in lateral view. Ovary (at anthesis) ca. ½ inferior, 3-celled, narrowly elliptic, glabrous apically. Style 5–6 mm long, 0.5 mm wide, glabrous, declinate and somewhat incurved distally; stigma rounded to subtruncate. Fruit a many-seeded loculicidal capsule ca. 5–6 mm long and 4.5–5 mm diam. Seeds narrowly pyramidate, cuneate and angulate, 2–2.5 mm long, white or beige, glabrous but vaguely papillate on the angles.

Distribution. Known only from montane forests of the Fortuna Dam watershed above Río Hornito at 1,100–1,250 m in Chiriquí Province, Panama.

Additional specimen examined. PANAMA. CHIRIQUÍ: vicinity of Fortuna Dam along trail near Río Hornito, ca. 8°45′N, 82°15′W. Forest ca. 1,100 m, 8 Aug. 1986 (fr), *McPherson 9877* (CAS).

In the size, shape, and indument of its leaves, *T. gordonii* most closely resembles *T. cenepensis*. The latter differs in the following characters: anther sacs of the larger stamens are linear-oblong and conspicuously retuse or bifurcate distally for about 0.5 mm; anther sacs of the smaller stamens are bifurcate for the distal two-thirds of their length and have connectives that are obscurely lobed but not prolonged into biauriculate appendages; the ovary is puberulent; the petals are copiously furfuraceous-lepidote abaxially; and the hypanthia are markedly constricted below the torus into a tubular neck that shortens to a tight constriction on fruiting hypanthia. *Tessmannianthus cenepensis* also appears to differ in other modal tendencies. Its inflorescences are longer (5–8 cm) and more floriferous than those of *T. gordonii*, and its petals are broadly ovate and appear to lack a well-developed basal claw. The consistency of these latter differences will become apparent only when better flowering material is available for study.

This species is named for Gordon McPherson (1947–), collector of the type and all other known Panamanian specimens of this genus. His many fine collections of trees, shrubs, and epiphytes have added a number of new and interesting species to the flora of Panama.

THE GENUS *ARGOSTEMMA* (RUBIACEAE—ARGOSTEMMATEAE) IN BORNEO[1]

Birgitta Bremer[2]

ABSTRACT

Argostemma is a large paleotropical genus of the tribe Argostemmateae. From Borneo 28 species are recognized. All are herbs growing in rainforests. Six species, *A. apiculatum*, *A. burttii*, *A. geesinkii*, *A. gaharuense*, *A. brookei*, and *A. calcicolum*, are new. There is one new name, *A. chaii*. *Argostemma* is the larger genus of the tribe; the other genus is *Neurocalyx*. The sister group to the Argostemmateae is the mainly Central American tribe Hamelieae. These two tribes form a monophyletic group within the subfamily Rubioideae. About two-thirds of the *Argostemma* species are endemic to Borneo. The species belong to at least three different monophyletic groups, each having its sister group outside Borneo. Nomenclature, descriptions, illustrations, maps, and a key for all species are provided.

Argostemma Wall. in Roxb. is a large, complex genus with about 220 described species. The revision of the genus will be published in parts dealing with different geographical areas. About 51 taxa have been described from Borneo. There is no treatment covering the whole island. In this study I have recognized 28 species, of which six are new. Most of the 28 species are endemic to Borneo, although six of them were described from specimens collected outside of Borneo. The remaining 22 are typified on Borneo specimens.

Only synonyms typified by specimens from Borneo are listed under the species.

During the 1950s, the late Dr. Bakhuizen van den Brink, Jr. studied the genus for the Flora Malesiana project. He annotated many herbarium labels about typifications. I have studied his lectotypifications, and in most cases I do agree with him, and have accepted the lectotypifications which are published in this paper.

No infraspecific taxa are recognized in this study. Most species are stenomorphous, and a few species are polymorphous. Among the latter, *A. elatostemma* occurs as two differing populations on Borneo, but since its whole variation outside Borneo is not yet known, they are not recognized as separate taxa. The substantial variation in *A. borragineum* is not correlated with geographical distribution and does not reveal distinct evolutionary lines. *Argostemma hameliifolium* and *A. moultonii* form a complex without discrete infraspecific units. The distinction between the two species is more or less preliminary. *Argostemma densifolium* is dimorphic, but as the variation seems small, I have treated the two morphs as one taxon.

MATERIALS AND METHODS

All cited specimens including types have been studied, unless otherwise stated. I have seen material from the following herbaria: A, AAU, B, BM, BO, BR, E, G, GH, HBG, K, KLU, L, MO, NY, P, S, SAR, SING, U, UC, and US.

I have studied *Argostemma parvifolium*, *A. elatostemma*, *A. ophirense*, *A. rupestre*, *A. hameliifolium*, *A. moultonii*, *A. gracile*, *A. havilandii*, *A. calcicolum*, *A. psychotrioides*, and *A. bryophilum* in the field. Material of most of these species was fixed in the field and later embedded and sectioned for anatomical studies of leaves, an-

[1] I am grateful to Mr. Paul Chai and his staff at the Forest Department at Kuching for assistance during my fieldwork, to the late Dr. Bakhuizen van den Brink, Jr. for much information about the genus, to Dr. John Dwyer for checking my Latin diagnoses, as well as to Mrs. Gunilla Hägglund, Miss Kerstin Kustås, and Miss Mari Källersjö for technical assistance. I am also indebted to the directors and curators of the herbaria listed in the Materials & Methods and to the reviewers for many useful comments. I thank Dr. Peter Raven, Director of the Missouri Botanical Garden, where I finished this study. Financial support from the Swedish Institute, the Royal Academy of Sciences, Stockholm, the Swedish Natural Science Research Council, and the University of Stockholm is gratefully acknowledged.

[2] Department of Botany, University of Stockholm, S-106 91 Stockholm, Sweden.

thers, and ovaries. For endothecial structure, whole anthers of all species were mounted in Hoyer's solution for study.

The species are arranged roughly in phylogenetic order. Species 1–12 (the *A. parvifolium* group) belong to one evolutionary group, species 13–26 (the *A. psychotrioides* group) to a second group, species 28 (*A. neurocalyx*) to a third group, and species 27 (*A. bryophilum*) assumes an uncertain position within the genus.

The drawings are my own. In the figures (4–31), all details of plants indicated by the same letter (B–I) are drawn at the same magnification and illustrate the same plant part. Hence, if a particular part is not illustrated, the corresponding letter is not used in the figure. The branch, indicated by letter A, is drawn twice as large in Figures 7–15, 17, 19–22, 30, and 31 as in Figures 4–6, 16, 18, and 23–29.

Systematic Position and Interrelationships within *Argostemma*

Argostemma is the largest genus of the Argostemmateae (Verdcourt, 1958; B. Bremer, 1987; Argostemmatideae fide Darwin, 1975, sphalm., pers. comm.). The other genus of the tribe is *Neurocalyx* (B. Bremer, 1979), a small genus endemic to Sri Lanka and southern India. The sister group to the Argostemmateae is the mainly Central American tribe Hamelieae (B. Bremer, 1987). These two tribes form a monophyletic group within the subfamily Rubioideae.

In Borneo there are 28 species of *Argostemma*. About two-thirds of these are endemic. The Bornean species belong to at least three different monophyletic groups, each having its sister group outside Borneo.

The *A. parvifolium* group is represented by species 1–12, characterized by "radial" endothecium (see morphological notes), anisophyllous leaves, rotate corollas, a narrowly ovoidal anther cone, thin and smooth apical appendages, and a glabrous style with a hardly widened to slightly capitate stigma. Three species from this group (*A. parvifolium*, *A. elatostemma*, and *A. ophirense*) also occur in the Malay Peninsula and on other Sunda Islands.

The *A. psychotrioides* group, species 13–26, is characterized by a sturdy connective, umbelliform inflorescences, in most species a corolla cleft to less than half its length, and usually a style much longer than the stamens. Most species also have a "polarized" endothecium (one species cannot be classified as "radial" or "polarized"), and most species have an endothecium with distinct cell margins (see morphological notes). *Argostemma hameliifolium*, *A. moultonii*, *A. psychotrioides*, and *A. borragineum* also occur on other Sunda Islands but not in the Malay Peninsula.

The remaining species, *A. bryophilum* (27) and *A. neurocalyx* (28), are more isolated. *Argostemma neurocalyx* belongs to a totally different group within *Argostemma*. It is characterized by an apical leaf rosette and free stamens, of which the anthers open by pores instead of slits. The group to which it belongs has a very wide distribution from West Africa to the Philippines. The systematic position of *A. bryophilum* is not yet clear. It does not fit in any of the groups mentioned above and is part of a complex of taxa common in the Philippines and New Guinea.

Morphological Notes

Raphides. Raphides are found in most parts of the plants and can be seen easily in corollas or in young glabrous stems.

Colleters. On living material the colleters can be seen easily, but on old dry specimens they are hardly visible. They are of the standard rubiaceous type (Lersten, 1975), with elongated axial cells surrounded by a palisade epidermal layer. The colleters are found singly or a few together between the calyx lobes. At each node they surround the stem in a ring and occur on the adaxial side of the petiole and at stipule bases. In species with few colleters in each ring, the colleters are generally round in outline, whereas in species with a dense ring of several hundred colleters they are narrow, often reduced, and almost without a palisade epidermis (Lersten, 1974). The stipules often end in apical colleters. In *Argostemma chaii*, with fringed stipules, each of the processes making up the fringe ends in a distinct colleter.

Hairs. In Borneo, only *A. apiculatum* is glabrous. The other species are more or less entirely or partially pubescent. There are no substantial differences between hairs on vegetative organs and those on flowers. Normal hairs are monoseriate and completely septate, with thin to very thick walls, and they generally do not collapse when dry. They may occur all over the leaf surfaces or only on (or rarely only between) the veins. If there is indumentum on the inside of the corolla or on the style, the hairs are shorter, mostly one- or few-celled and thinner (Verdcourt, 1958). Another hair type occurs on, e.g., *A. rupestre* (Fig. 13I) and *A. gee-*

sinkii (Fig. 14I). On the upper leaf surfaces of these species there are three or five rows of stiff, pluricellular hairs. One row occurs along the midrib and the others along the margins, making them appear more or less serrulate.

Leaf anatomy. I have studied in detail cross sections of field-fixed material of *A. bryophilum*, *A. elatostemma*, *A. havilandii*, *A. moultonii*, *A. ophirense*, *A. psychotrioides*, and *A. rupestre*. Cross sections of young leaves of the species are generally very similar. With the exception of *A. bryophilum*, cross sections of these species can be described as follows: upper epidermis of one layer of large, rectangular cells with rather thin walls and lacking plastids; palisade chlorenchyma of one or a few layers of small carrot-shaped cells filled with plastids; spongy parenchyma of a few to many layers of small to medium-sized cells almost without plastids; lower epidermis of one layer of large, rounded cells with thin walls and without plastids; stomata quite exposed. This type of leaf also occurs in *Neurocalyx* (B. Bremer, unpubl.). *Argostemma bryophilum*, aberrant in many other ways, differs from the others in leaf cross section. Its epidermal layers are thinner with smaller cells, and the chlorenchyma consists of large rounded cells with few plastids.

Species whose lower leaf surface appears white (e.g., *A. rupestre* and *A. gracile*) have more intercellular spaces in the spongy parenchyma than other species.

Endothecium. The endothecium of *Argostemma* (Fig. 1) was studied with light microscope on whole mounts of anthers. The endothecium varies between groups of *Argostemma* species. In *A. bryophilum* and *A. neurocalyx*, in many ways aberrant species, only narrow longitudinal bands of cells close to the stomium have wall thickenings, while in all other species from Borneo, wall thickenings occur in all cells of the endothecial layer. In the following, the terms endothecium, endothecial layer, and endothecial type will only be used for those cells with wall thickenings.

The endothecial cells are generally elongated longitudinally or horizontally compared with the line of dehiscence and with the anther-length axis, or rarely they are isodiametric. In *Argostemma* the wall thickenings are U-shaped ribs arranged transversely in relation to the longest axis of the cell and with their openings toward the epidermal layer. The ribs end in knobs.

Dormer (1962), Nordenstam (1978), Noel (1983), and French (1985) have shown the systematic significance of endothecial structures. This study shows that different endothecium types occur in *Argostemma* and that these types are restricted to different systematic units within the genus. Dormer (1962) and Noel (1983) presented systems for classification of endothecial structures. Dormer (1962) classified endothecial cells in the Compositae as "polarized" or "radial." In a polarized endothecium the thickenings are concentrated mainly at the upper and lower ends of the cells, and when ribs occur they are parallel to the line of dehiscence. In a radial endothecium the cells are ribbed all around; on elongated cells the bars are arranged transversely, parallel to the line of dehiscence. I have found Dormer's system somewhat difficult to use with Rubiaceae because the endothecial cells are different, often elongated horizontally, i.e., transversely to the anther-length axis. In Compositae (Nordenstam, 1978; Dormer, 1962; K. Bremer, pers. comm.), when the cells are elongated, the elongation is parallel to the anther-length axis.

Noel (1983) presented a more general system which embraces over 500 taxa from different families. He distinguished several endothecial characters, such as size and shape of the cells, organization of the thickenings, whether a basal plate and/or ribs occur, and the shape and number of these. In general, the endothecial cells of *Argostemma* can be characterized following Noel's scheme (1983: 837): cells medium-sized, 27–60 μm on the longest side, isodiametric, rectangular or fusiform; wall thickenings localized; base plate absent; ribs U-shaped; 5–ca. 15 ribs per cell (in several species the cell margins become indistinct, and it is difficult to see where the cell ends); spacing from close to wide; branching absent; tips knobbed.

There are four types of endothecial cells in *Argostemma*. The first two are "polarized." In the first type, in *A. bryophilum*, *A. hameliifolium* (Fig. 1A), *A. moultonii*, and *A. neurocalyx*, the cell margins become indistinct, and the endothecial layer can be described as consisting of long, horizontal, rather narrow bands with many close distinct transverse ribs and knobs. This type also occurs in the sister genus *Neurocalyx*. I have examined the endothecia of *Hamelia patens*, *Hoffmannia vesciculifera*, and *Xerococcus congestus*, belonging to Hameliieae, the sister tribe to Argostemmateae (B. Bremer, 1987), and they are of the same type.

In the second type (e.g., *A. enerve*, *A. gracile*, *A. havilandii*, and *A. psychotrioides* (Fig. 1B)), the cells are horizontally elongated and fusiform but with distinct cell margins. The ribs are not as close together, and the knobs are larger than in the first type.

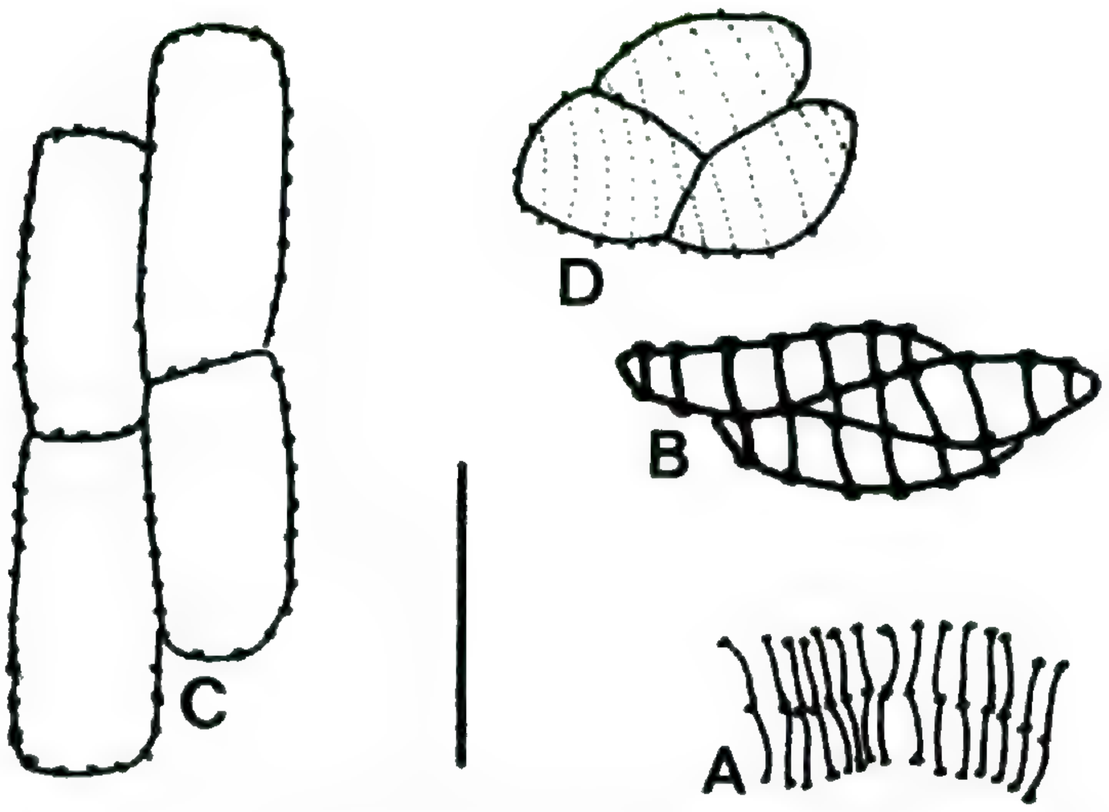

FIGURE 1. Endothecial cell thickenings. Scale bar = 50 μm—A. *Argostemma hameliifolium*.—B. *A. psychotrioides*.—C. *A. parvifolium*.—D. *A. borragineum*.

The third type could be classified as "radial." This type occurs in many species, e.g., *A. ophirense*, *A. parvifolium* (Fig. 1C), and *A. rupestre*. The cells are generally rectangular, with the longitudinal axis parallel to the dehiscence line. The cells are larger than in the "polarized" group. The transverse ribs are indistinct to hardly visible, and the knobs are smaller and look like a string of pearls surrounding the cell margins.

The fourth group consists solely of *A. borragineum* (Fig. 1D), whose endothecium is unique at least among the Borneo species of *Argostemma*. The cells are generally isodiametric and large. The ribs are indistinct, generally arranged parallel to the dehiscence line, and the knobs are indistinct. Since the ribs are not transversely arranged in relation to the anther-length axis, this type cannot be described as "radial," and since the knobs surround the cells on all margins, it cannot be described as "polarized."

Fruit. After anthesis the pedicels and peduncles become erect. These parts and the fruit, crowned with the calyx lobes, become fleshy and succulent. The fruit opens by an apical operculum. Such fleshy capsules are not uncommon in the tropics (Ehrendorfer, 1983: 829). Bakhuizen f. (1975) said about fruits of Rubiaceae:

> I am convinced that true capsules are not found in Rubiaceae. The rubiaceous "capsules" distinctly possess a (very) thin, often leathery endocarp. For that reason I propose to distinguish two main types of fruits in Rubiaceae: pyreniferous and non-pyreniferous. The pyreniferous fruits may be subdivided into pachypericarpous (having a thick, fleshy pericarp, known as "drupe") and leptopericarpous (having a (very) thin, dry, often leathery pericarp, so-called "capsule"). Non-pyreniferous fruits are conventionally termed "berry."

The fruit of *Argostemma* does not fit into this system. Although Bakhuizen f. was an expert on this genus, he had never seen it in the field (pers. comm.), and on dry material he had probably misinterpreted the fruit type.

When the fruit is open the fibrous endocarp separates from the remaining pericarp and splits into threads, which are visible in the opening. The septum, with the attached placentas, is also fibrous and will split. Among the resulting threads the numerous seeds will be exposed. Perhaps the threads prevent sudden dispersal. It is not uncommon to find specimens with many seeds germinated within the capsules. This kind of "vivipary" or germination in situ is described earlier from *Ophiorrhiza tomentosa* (Tan & Rao, 1981).

Placentation. Placentation is axile with the placentas (Fig. 2) attached at the top of the septum. The placentas are stalked, pendulous, fleshy, and in front view broadly ovoidal to kidney-shaped.

Seeds. *Argostemma* has numerous, small (ca. 0.5 mm), angular to ovoidal seeds (Fig. 3). The testa seems to be unique to this genus. The surface is mostly reticulate with a mamilla or a ring in each cell.

DISTRIBUTION

The maps (1–28) of *Argostemma* show that most localities are from northwestern Borneo. This is not because *Argostemma* is more common there, but indicates that this part, Sarawak, is botanically most well known. The same pattern can be seen in *Memecylon* (K. Bremer, 1983) and other genera. The few localities in Kalimantan result from comparatively few botanical expeditions, and large areas of former rainforest have been deforested.

Taxonomically, *Argostemma* in Borneo belongs to at least three different species groups which are more or less sympatric, and many species within the same group are sympatric. The distributions of different species of *Argostemma* are influenced by altitude, a fact that is hardly evident on the maps. *Argostemma elatostemma*, *A. densifolium*, *A. gaharuense*, *A. chaii*, *A. havilandii*, *A. calcicolum*, *A. trichosanthes*, *A. psychotrioides*, and *A. variegatum* grow only at low altitude; and *A. anisophyllum*, *A. dulitense*, *A. apiculatum*, *A. burttii*, *A. geesinkii*, *A. gracile*, *A. brachyantherum*, and *A. brookei* grow only at altitudes over 1,000 m. Some species occur at both low and high altitudes: *A. parvifolium*, *A. subfalcifolium*, *A. ophirense*, *A. rupestre*, *A. hameliifolium*, *A. moultonii*, and *A. borragineum*.

Most of the lowland species and those growing

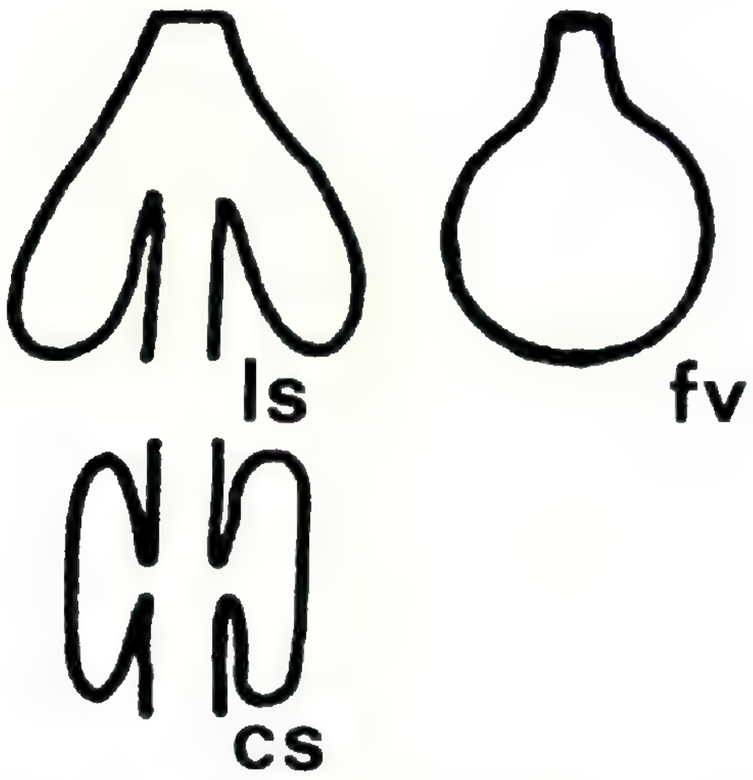

FIGURE 2. Placenta in ripe fruit (diagrammatic). ls, longitudinal section; fv, front view; cs, cross section.

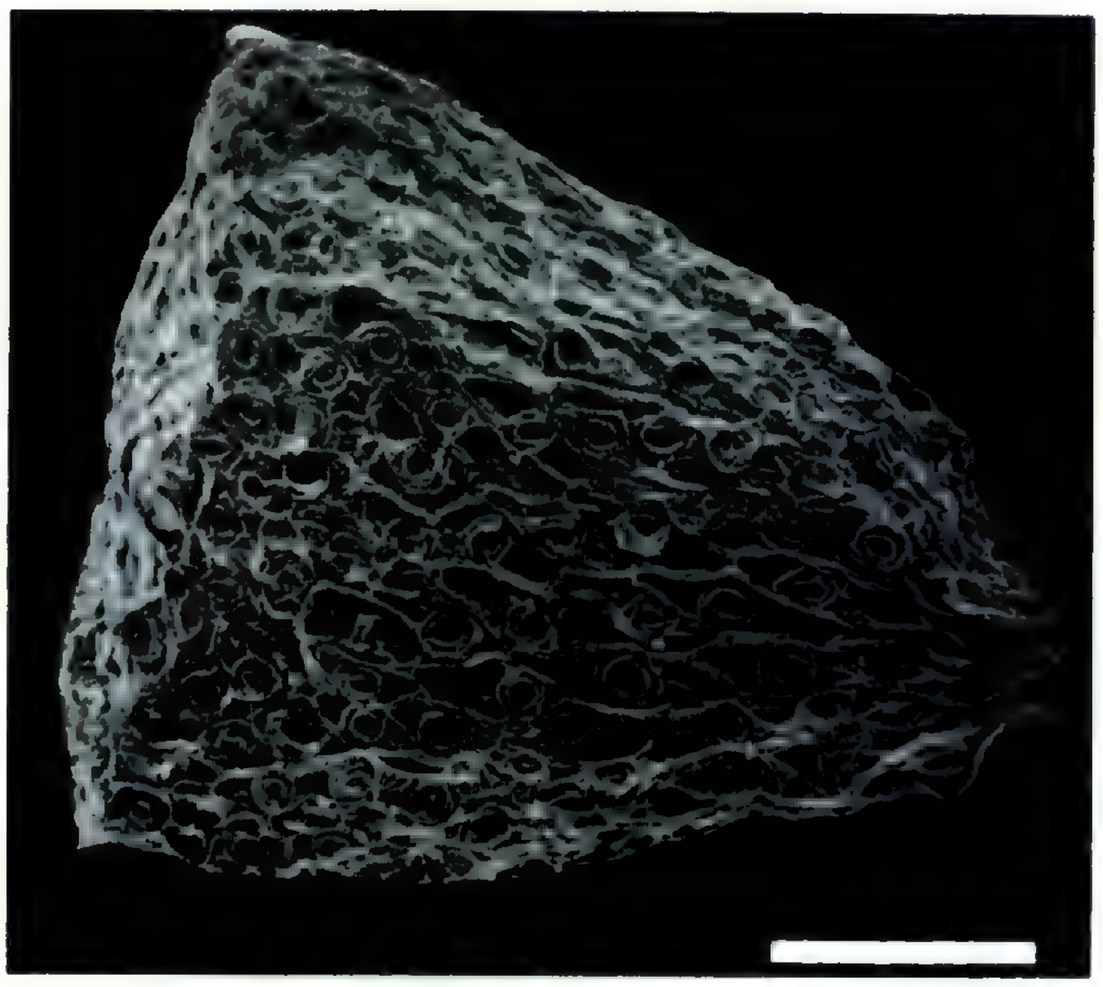

FIGURE 3. Seed of *A. borragineum* in SEM surface view. From *Bremer 1668* (S). Scale bar = 100 μm.

from low to high altitude are widespread, and many of them are sympatric. Of the eight species known only from a single locality each, four are from high altitude, the altitudes of three are unknown, and only one is from low altitude (ca. 700 m).

TAXONOMIC TREATMENT

Argostemma Wall. in Roxb., Flora Indica 2: 324, 1824. *Pomangium* Reinwardt, Syll. Pl. Rat. 2: 10. 1825. *Argostemmella* Ridley, J. Bot. 65: 41. 1927. TYPE: *Argostemma sarmentosum* Wall. (Pfeiffer, Nomenclator Botanicus, 1873).

Erect, suberect, or creeping herbs, isophyllous or anisophyllous, glabrous to densely pubescent, often succulent. Stem usually unbranched or slightly branched, often succulent; internodes very short to 85 mm long. Leaves opposite or verticillate, when anisophyllous unequal, scattered along the stems, or decussate, or distichous, or rosulate on a short stem, or apically rosulate on a well-developed stem, herbaceous, or coriaceous, or membranaceous; stipules interpetiolar, persistent or deciduous, small to large, usually entire, rarely slightly cleft or fringed, with colleters near the base on the adaxial side or rarely at the apex, if fringed then with a colleter at each point; midrib distinct, the primary veins distinct or obscure, the veinlets generally not visible. Anisophyllous leaves with the small (nanophyllous) leaf persistent or deciduous, similar in shape to the stipules or to the larger leaf, often cordiform, with or without a short petiole. Inflorescences terminal, subterminal or rarely axillary, solitary or a few together, 1–160-flowered, cymose, corymbiform to umbelliform, glabrous or pubescent; peduncles up to 10 cm long or rarely absent; bracts often persistent and small; pedicels in fruiting stage succulent. Flowers (4–)5(–6)-merous, actinomorphic or rarely zygomorphic, perfect. Calyx with a very short tube; lobes shorter or rarely as long as the corolla lobes, erect or spreading to reflexed, in fruiting stage succulent, glabrous or pubescent. Corolla with valvate aestivation, white, sometimes with green nectar guides at the base, rotate, or subcampanulate but with recurved lobes, or campanulate, 3–12 mm long, with the tube more than ⅔ as long as the lobes, externally glabrous or pubescent, internally glabrous or pubescent with the pubescence often only on the lobes; lobes erect-spreading to recurved or reflexed. Stamens 4 or 5(6), equal in number to the corolla lobes, inserted near the base of the corolla, introrse, coherent into an anther cone or free; if coherent then fused along the whole anther or partially so; thecae with two sacs (loculi); anthers bright yellow to cream-colored, erect or slightly upcurved; filaments free, short or long, mostly equal, erect or rarely curved, smooth, glabrous; sacs opening by vertical slits, rarely with pores; apical appendages ca. ½ as long as the anther or absent, thin to coriaceous, smooth to papillose; connectives distinct to indistinct from the thecae, smooth to papillose. Ovary 2-celled; style filiform, glabrous to pubescent, shortly to long-exserted, with a capitate, clavate, or scarcely widened stigma, shallowly to rarely distinctly bifid. Fruit a succulent capsule with a fibrous endocarp, opening by an apical operculum, smooth or rarely with emergences, furrows, or ribs (at least on dry specimens), glabrous to densely pubescent. Seeds brown, numerous, minute, angular or ovoid, the testa generally reticulate with a central mamilla or ring in each cavity.

KEY TO THE SPECIES OF *ARGOSTEMMA* IN BORNEO

1a. Leaves more or less condensed into an apical rosette. Stamens free at least after anthesis 2
2a. Leaves membranaceous. Corolla campanulate, not deeply cleft. Stamens opening by apical pores ..... 28. *A. neurocalyx*
2b. Leaves herbaceous to coriaceous. Corolla rotate, cleft to near the base. Stamens opening by longitudinal slits ..... 17. *A. chaii*
1b. Leaves scattered along the stem, not condensed into an apical rosette. Stamens connate or free 3
3a. Leaves anisophyllous 4
(See also the insufficiently known 16. *A. flavescens* not included in the key.)
4a. Corolla cleft to near the base, starlike; lobes spreading, erect-spreading, or rarely reflexed, never recurved. Stamens as high as the style with stigma only slightly exserted 5
5a. Flowers slightly zygomorphic. Calyx lobes almost as long as the corolla lobes. Filaments unequal, curved ..... 1. *A. parvifolium*
5b. Flowers actinomorphic. Calyx lobes much shorter than the corolla lobes. Filaments equal, straight 6
6a. Plant creeping. The larger of the anisophyllous leaf pair basally very unequal-sided. Peduncles and the outside of the corolla pubescent. Anther cone black when pressed and dried ..... 2. *A. elatostemma*
6b. Plant erect or creeping. The larger of the anisophyllous leaf pair unequal- or equal-sided. Peduncles and the outside of the corolla generally glabrous. Anther cone not black when pressed and dried 7
7a. Larger leaf of the anisophyllous pair generally subfalcate; nanophyllous leaves lanceolate. Fruits with longitudinal furrows ..... 3. *A. subfalcifolium*
7b. Larger leaf of the anisophyllous pair not subfalcate; nanophyllous leaves cordiform, ovate or lanceolate. Fruits without furrows but rarely with 5 ribs 8
8a. The larger of the anisophyllous leaf pair basally unequal-sided or oblique; nanophyllous leaves cordiform 9
9a. Stems and leaf veins pubescent. Leaves herbaceous or coriaceous. Corolla up to ca. 6 mm long 10
10a. Plant a rosette or creeping with generally short internodes and obovate to oblanceolate leaves ..... 4. *A. densifolium*
10b. Plant erect with obvious internodes and lanceolate to linear leaves ..... 5. *A. ophirense*
9b. Stems and leaves glabrous or glabrate. Leaves herbaceous to membranaceous. Corolla 8–9 mm long ..... 6. *A. anisophyllum*
8b. The larger of the anisophyllous leaf pair basally equal-sided; nanophyllous leaves ovate, elliptic, or lanceolate 11
11a. Leaves without stiff pluricellular hairs 12
12a. Leaves pubescent. Corolla ca. 4 mm long, lobes reflexed. Fruit with 5 ribs ..... 12. *A. gaharuense*
12b. Leaves glabrous. Corolla more than 9 mm long, lobes not reflexed. Fruit without ribs 13
13a. Stems pubescent. Leaves coriaceous with pale lower surfaces. Apical appendage ca. ⅓ of the anther length ..... 7. *A. dulitense*
13b. Stems and whole plant glabrous. Leaves herbaceous to membranaceous, both sides of the same color. Apical appendage ca. ¼ of the anther length ..... 8. *A. apiculatum*
11b. Leaves with stiff pluricellular hairs in 3 or 5 rows 14
14a. Corolla ca. 9 mm long or more; lobes ovate, spreading. Apical appendage less than ¼ of the anther length ..... 9. *A. burttii*
14b. Corolla ca. 7 mm long or less; lobes ovate or lanceolate, erect-spreading. Apical appendage ca. ⅓ of the anther length 15
15a. Corolla lobes lanceolate, not pink in press. Stipules ovate to lanceolate ..... 10. *A. rupestre*
15b. Corolla lobes ovate, often pink in press. Stipules ovate to cordiform ..... 11. *A. geesinkii*
4b. Corolla generally cleft ½ its length or less; lobes recurved, erect, or spreading. Stamens shorter than the much-exserted stigma 16
16a. Corolla cleft to less than ⅓ its length; lobes erect or spreading 17
17a. Leaves distichous. Flowers solitary, almost sessile. Stigma disc-shaped and distinctly bifid ..... 18. *A. gracile*
17b. Leaves not distichous. Flowers in up to 12-flowered inflorescences, rarely solitary, with peduncles. Stigma capitate and indistinctly bifid ..... 19. *A. brachyantherum*
16b. Corolla cleft to at least ½ its length; lobes recurved 18
18a. Corolla cleft to near the base. Stamens free at anthesis. Stigma slightly capitate ..... 20. *A. brookei*
18b. Corolla cleft to ca. ½ its length. Stamens connate at anthesis. Stigma clavate 19

19a. Calyx lobes 2–6 mm long, distinctly reflexed. Style generally glabrous 20
20a. Plant erect. Leaves basally acute to cuneate or attenuate and equal-sided ..... 25. *A. psychotrioides*
20b. Plant creeping. Leaves basally rounded to obtuse and unequal-sided ..... 26. *A. variegatum*
19b. Calyx lobes up to 1 mm long, erect. Style generally pubescent 21
21a. Stems green, smooth. Nanophyllous leaves persistent, cordiform ..... 24. *A. humifusum*
21b. Stems in lower part generally pale brown to gray with elevated corky to papery longitudinal ridges. Nanophyllous leaves deciduous, lanceolate to linear ..... 21. *A. havilandii*

3b. Leaves isophyllous 22
22a. Corolla cleft to near the base, starlike; lobes spreading or reflexed 23
23a. Leaves membranaceous. Stipules persistent, broadly ovate to cordiform. Inflorescences 1–2-flowered. Apical anther appendages almost wanting ..... 27. *A. bryophilum*
23b. Leaves herbaceous. Stipules deciduous. Inflorescences 3–40-flowered. Apical anther appendages form open cylinders (Figs. 16, 17) 24
24a. Plant 10–100 cm, erect. Stamens with short filaments and short apical appendages ..... 13. *A. hameliifolium*
24b. Plant 2–40 cm, more or less creeping. Stamens with long filaments and long apical appendages ..... 14. *A. moultonii*
22b. Corolla cleft to ca. ½ its length; lobes recurved 25
25a. Stems generally pale brown to gray with elevated corky to papery longitudinal ridges, without scars. Anther cone with connate apical appendages. Stigma clavate. Fruit smooth 26
26a. Plant wholly covered with a dense indumentum of stiff long hairs ..... 23. *A. trichosanthes*
26b. Plant slightly pubescent with soft hairs ..... 22. *A. calcicolum*
25b. Stems generally black with wavy scars, without longitudinal ridges. Anther cone with free apical appendages. Stigma capitate. Fruit with emergences ..... 15. *A. borragineum*

1. Argostemma parvifolium Benn., Plantae Javanicae Rariores. 1: 96. 1838. TYPE: Java(?), Sumatra: *Horsfield s.n.* (holotype, BM). Figure 4.

Erect, anisophyllous, densely pubescent herb. Stem 15–50 cm long, usually unbranched, densely pubescent; internodes 6–15 mm. Leaves opposite, very unequal; stipules persistent, 4–7 mm long, ovate to cordiform, acute to acuminate at apex; larger leaves of the anisophyllous pairs with pubescent petioles 3–6 mm long, the lamina 4–13 × 1.4–3 cm, generally oblanceolate or obovate to elliptic, basally acute and oblique, marginally serrulate, apically acuminate, herbaceous, pubescent on both surfaces; midrib and primary veins (9–18 pairs) distinct. Nanophyllous leaves persistent, 5–10(–32) mm long, cordiform to ovate. Inflorescences solitary or a few together, 1–9-flowered, corymbiform, pubescent; peduncle 0.9–3.2 cm long, bracts to 1 cm long, broadly ovate to lanceolate; lateral branches, if present, to 1.5 cm long; pedicels 0.7–1.4 cm long. Flowers 5-merous, slightly zygomorphic; calyx lobes 4–6 mm long, triangular to ovate, acuminate, pubescent; corolla 5–6 mm long, cleft to near the base, externally pubescent, internally glabrous; lobes triangular, spreading. Stamens 6–10 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone narrowly ovoid, slightly upcurved; filaments short, unequal, curved; sacs opening completely and longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective distinct, smooth. Style 6–10 mm long, glabrous with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

There is a question mark after Java on the label of the type specimen, and on the label there is also written "Sumatra," as is indicated in the protologue. *Argostemma parvifolium* grows on sandstone, sandy banks, and cliffs near streams, from 350 to 1,450 m. The species is based on non-Borneo material. The habit of the Borneo population is similar to the type of *A. parvifolium* var. *involucratum* (Hemsl.) Bakh. f. I have not studied the complete variation of *A. parvifolium* outside Borneo, and so for now I avoid infraspecific taxa. Except for the inner floral parts, the whole plant is densely covered by long soft hairs. As in all *Argostemma* species, the flowers are slightly pendulous at anthesis, and in this species the flowers are slightly zygomorphic. The rotate corolla has at its center distinct green nectar guides on the upper half. The anther cone is bent upwards and the stamens, in the upper half of the flower, have curved filaments. It is the only Borneo species with these characters.

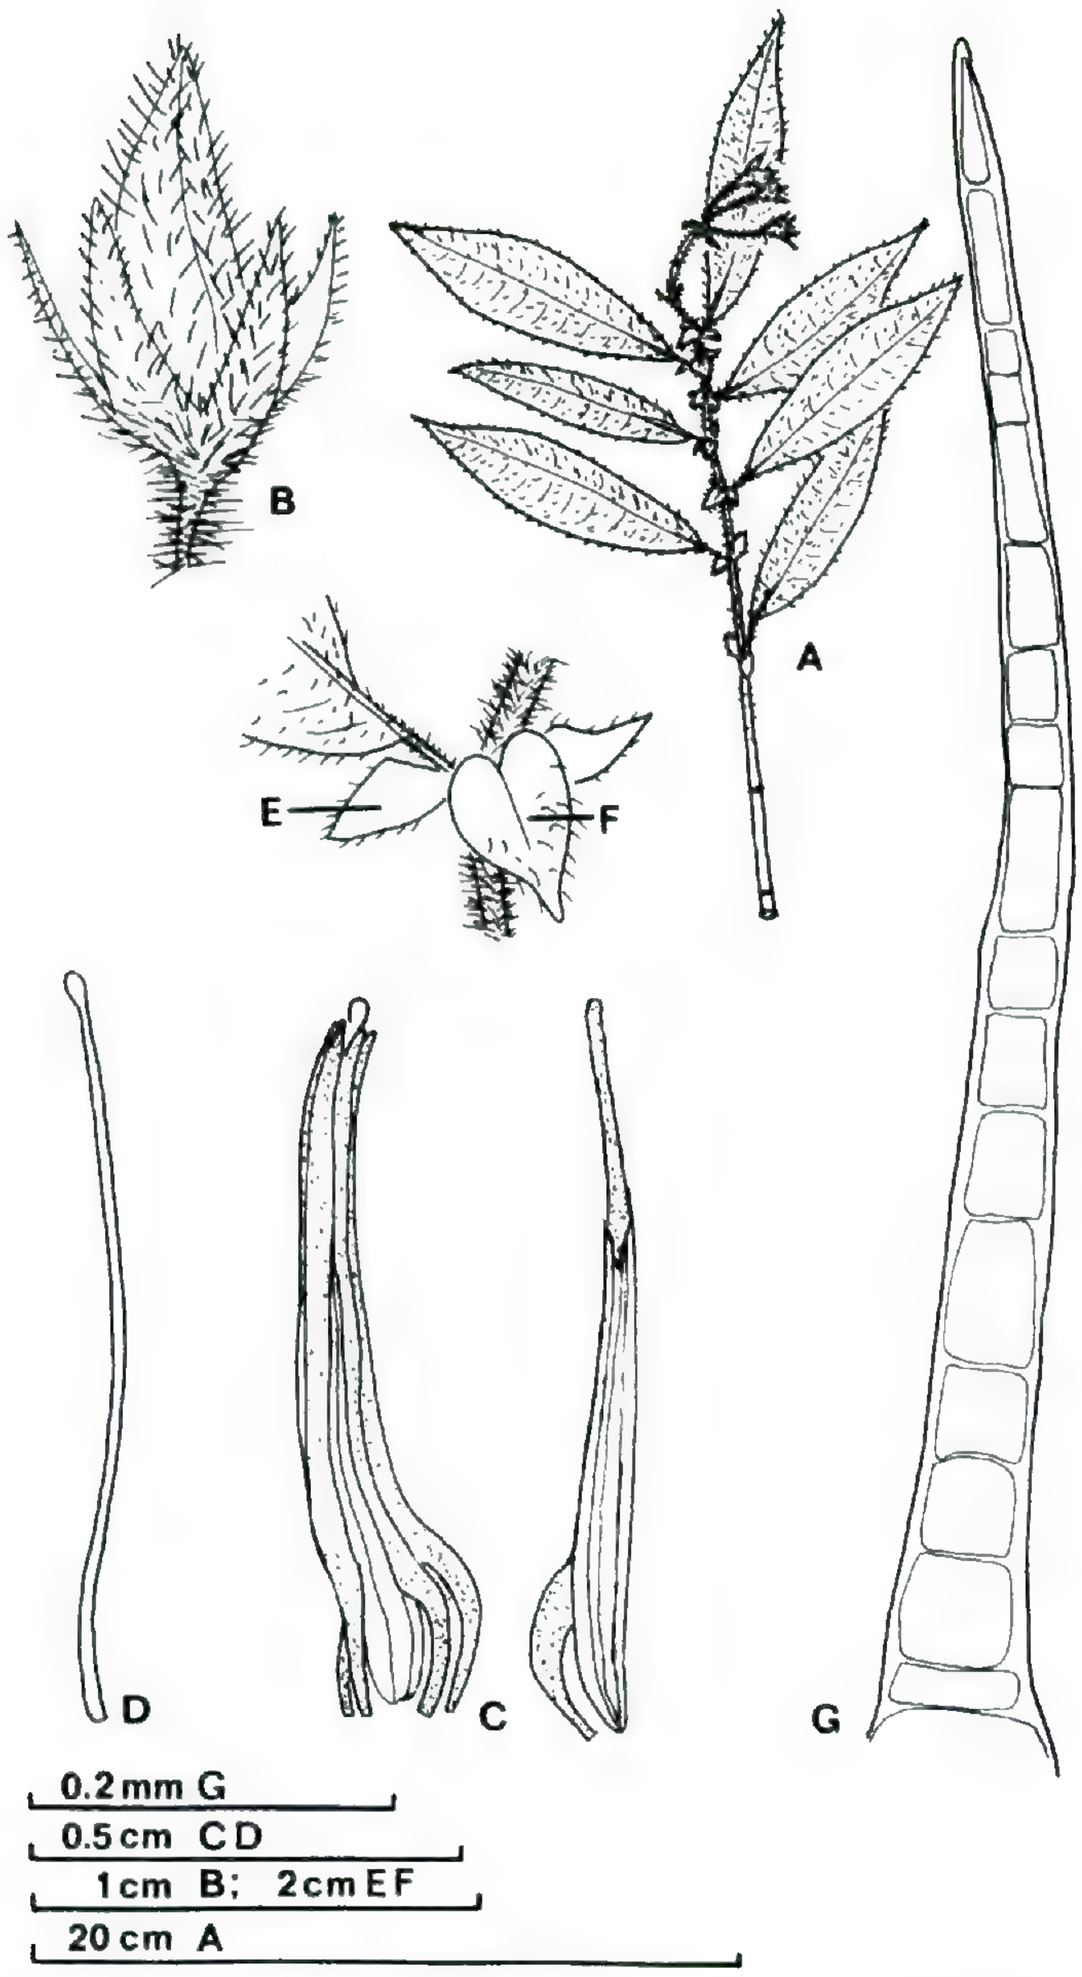

FIGURE 4. *Argostemma parvifolium.*—A. Branch.—B. Flower bud.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—G. Hair from outer surface of the corolla. A, C–F from *Burtt 11521* (E); B, G from *Winkler 767* (L).

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Gunong Berumput, 3,500 ft., 1962, *Burtt & Woods 2816* (E, SAR); 1st Div., Sabal, 350 m, 1979, *Bremer 1652* (S, SAR); 4th Div., Mt. Lambir, 1962, *Burtt & Woods 2366* (E, SAR); 1979, *Burtt 11521* (E, S); 1,200–1,500 ft., 1978, *Burtt 11640* (E, S); 1,450 m, 1976, *Ilias & Yeo S38349* (L, SAR); 7th Div., Hose Mts., 800 m, 1975, *Chai et al. S37338* (K, L, MO, SAR). KALIMANTAN: W Prov., Bidang Menabei, 700 m, 1924, *Winkler 767* (L).

2. Argostemma elatostemma Hook. f., The Flora of British India 3(7): 45. 1880. TYPE: Penang, *Griffith s.n.* (lectotype, K; Bakh. f. in herb., confirmed here). Figure 5.

A. motleyi Ridley, J. Bot. 65: 39. 1927. TYPE: Borneo: Bangarmassing, 1857–1858, *Motley 1174* (holotype, K).

Creeping, anisophyllous herb. Stem 2–36 cm long, slightly branched or unbranched, pubescent; internodes 5–25 mm. Leaves opposite, very unequal; stipules persistent, 4–10 mm long, ovate to broadly ovate or cordiform, acuminate to acute at apex; larger leaves of anisophyllous pairs with pubescent petioles 4–7 mm long; lamina 2–9.5 × 1.3–3.5 cm, obovate to ovate and slightly subfalcate, basally subcordate to auriculate with the lobes unequal, marginally entire, apically acute, herbaceous, glabrous above and with a few hairs on the veins below; midrib and primary veins (5–11 pairs) distinct. Nanophyllous leaves persistent, 4–12 mm long, cordiform. Inflorescences solitary, 1–20-flowered, densely corymbiform or umbelliform, pubescent; peduncle 0.8–4 cm long; bracts to 0.7 cm long, ovate or lanceolate; lateral branches, if present, to 2.5 cm long; pedicels 0.4–1 cm long. Flowers 5-merous; calyx lobes 1–2 mm long, ovate to triangular, acute, pubescent; corolla 5–6 mm long, cleft to near the base, externally pubescent, internally glabrous; lobes ovate to lanceolate, spreading. Stamens 5–6 mm long, coherent; anther cells and apical appendages connate; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 5–7 mm long, glabrous with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

Hooker based *A. elatostemma* on two collections, by *Lobb* and *Griffith*. Both are suitable for lectotypification. Bakhuizen f. (in herb.) selected the *Griffith* specimen in K, and I follow his choice.

Argostemma elatostemma grows in wet shady forests, from 100 to 750 m. It occurs in the first division of Sarawak and on the southern tip of Kalimantan. The collections from these two areas are different. The Sarawak specimens are alike and similar to the type collection from the Malay Peninsula, while the Kalimantan specimen, described as *A. motleyi*, agrees well with the type of *A. elatostemma* var. *obovata* King (1904). In this study I have not dealt with any infraspecific taxa because I have not yet studied the complete variation outside Borneo. The specimen from Kalimantan is smaller with shorter leaves, and there is only one flower in the collection. *Argostemma elatostemma* is characterized by its creeping habit, rooting at the nodes, silvery mottled leaves, and unequal leaf bases. The stems, petioles, veins of the lower leaf surfaces, and the inflorescences are densely pubescent. The flowers are rotate with a long pale anther cone which blackens in the press.

3. Argostemma subfalcifolium Bakh. f., Blumea 7: 332. 1953. TYPE: Borneo. Sarawak: Mt. Dulit, Dulit trail, ca. 100 m, 1932, *Richards 2090A* (holotype, K). Figure 6.

Erect, anisophyllous herb. Stem 15–35 cm long, unbranched, glabrous or sparsely pubescent; internodes 7–23(–45) mm long. Leaves opposite, very unequal; stipules deciduous or persistent, 5–12 mm long, ovate to lanceolate or broadly ovate, acute at apex; larger leaves of the anisophyllous pairs with glabrous or sparsely pubescent petioles 2–12 mm long; lamina 7–22 × 1.5–5 cm, generally subfalcate to lanceolate or ovate to obovate, basally acute and oblique, marginally entire or rarely serrulate, apically acuminate or rarely acute, herbaceous, generally glabrous on both surfaces or finely pubescent on the veins below; midrib and primary veins (6–15 pairs) distinct, rarely obscure. Nanophyllous leaves deciduous or persistent, 7–12 mm long, lanceolate. Inflorescences solitary or a few together, to 45-flowered, laxly corymbiform; peduncle 1.5–6 cm long, glabrous; bracts to 0.7 cm long, ovate to lanceolate; lateral branches 1–3.3 cm long, glabrous or pubescent; pedicels 0.5–1.2 cm long, pubescent. Flowers 5-merous; calyx lobes 2–4 mm long, ovate to triangular to lanceo-

late, acute to acuminate, ± glabrous; corolla 5–6.5 mm long, cleft to near the base, glabrate on both sides; lobes ovate to lanceolate, spreading. Stamens 5–7 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 5–7.5 mm long, glabrous with a slightly capitate stigma, shortly exserted. Fruit with distinct longitudinal furrows.

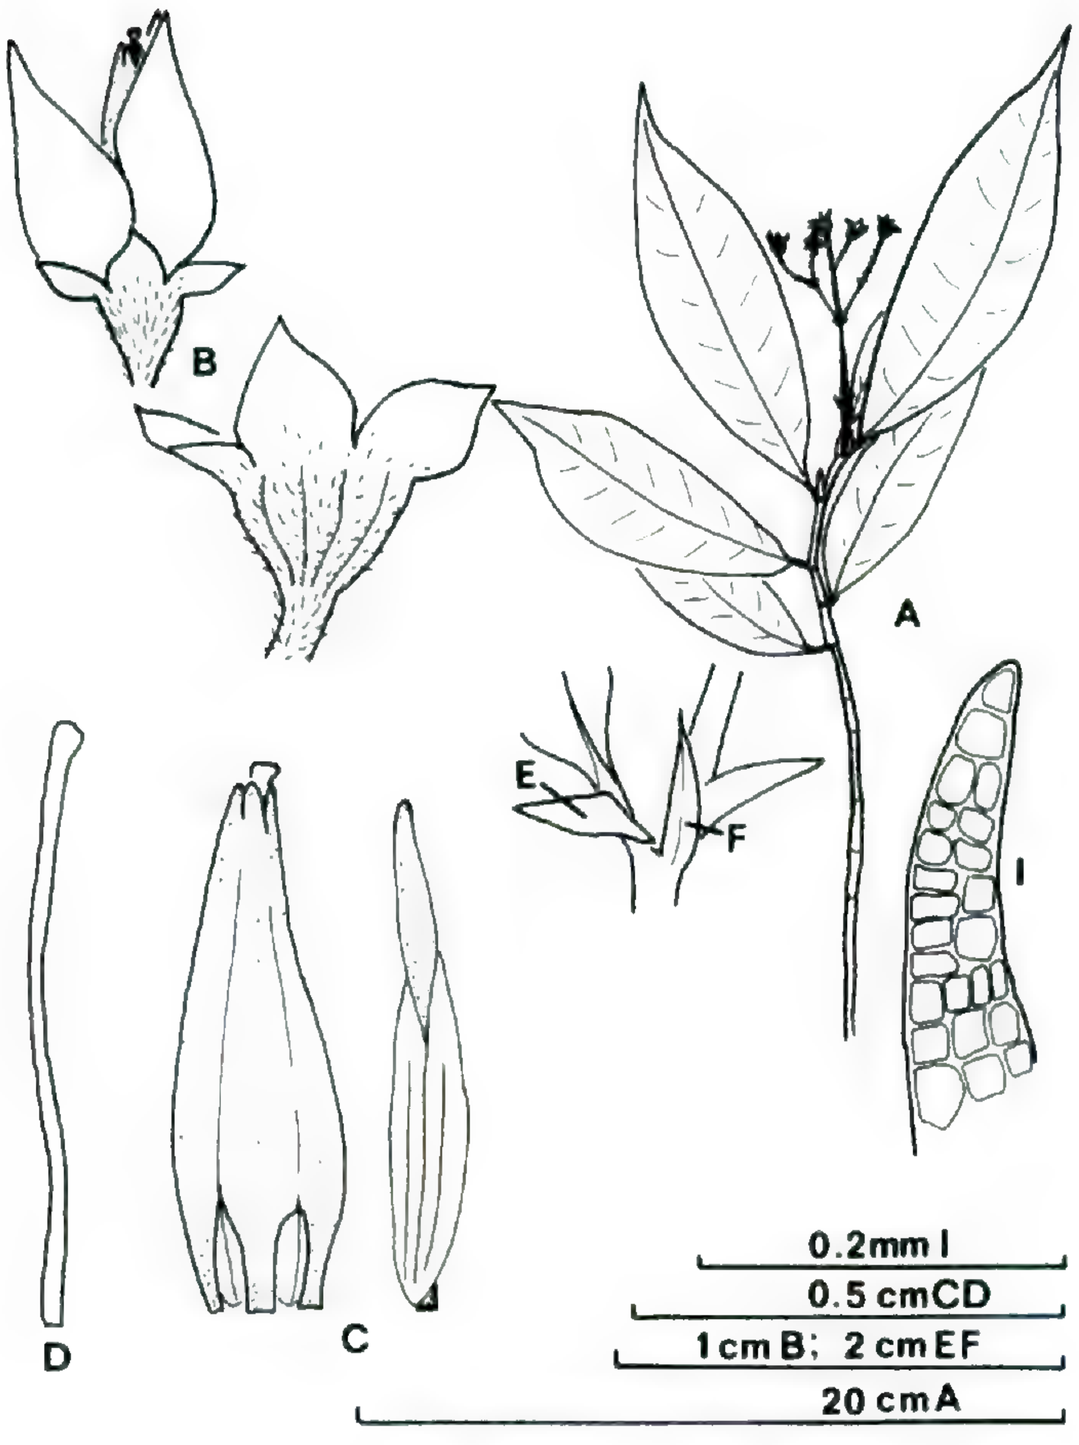

FIGURE 6. *Argostemma subfalcifolium*.—A. Flowering branch.—B. Flower and fruit.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—I. Stiff, pluricellular leaf hair. A, B (fruit) from *Clemens 30650* (NY); B (flower)–I from *Burtt 8228* (E).

Argostemma subfalcifolium grows in damp shady places in the lowland rainforest at altitudes from 100 to 1,500 m. It tends to have subfalcate leaves. The species is characterized by rather long calyx lobes and by furrowed fruits. The stems are glabrate and sometimes slightly pubescent. The peduncles and lateral branches of the inflorescence are mostly glabrous, whereas the pedicels, ovary, and lower part of the calyx lobes are pubescent. The flowers are rotate, and the buds are distinctly angular in cross section. The staminal cone is high. From the outside the thecae are completely shed by the connectives but can be seen as immersed sacs between the filaments.

There are a few aberrant specimens. *Anderson 4090*, from Bako in Sarawak, consists of very small plants. They were collected on fallen tree trunks and have a peculiar habit, but no other details contradict inclusion in this species. *Meijer 2286*, from Kalimantan, has nearly cordiform nanophyllous leaves, but otherwise fits. *Brooke 9194*, from Sarawak, has very narrow leaves with obscure primary veins.

Additional specimens examined. BORNEO. 4. Argostemma densifolium Ridley, J. Bot. 65: 39. 1927. TYPE: Borneo. Puak (near Lundu?), 1894, *Ridley 12448* (holotype, K; isotype, SING). Figure 7.

Argostemma densifolium var. *latifolium* Ridley, J. Bot. 65: 40. 1927. TYPE: British North Borneo: Bongaya, 1897, *Ridley s.n.* (holotype, SING).

Rosette or creeping, anisophyllous herb. Stem 5–16 cm long, slightly branched or unbranched, pubescent; internodes very short to 15 mm. Leaves opposite, very unequal; stipules persistent, 4–6 mm long, ovate to cordiform, obtuse to acuminate at apex; larger leaves of the anisophyllous pairs with pubescent petioles to 5 mm long; lamina 4–14 × 1–4.5 cm, obovate to oblanceolate, basally acute to subcordate and oblique or with the lobes unequal, marginally entire or serrulate, apically obtuse or acute, herbaceous, glabrous above and pubescent on the veins below; midrib and primary veins (10–17 pairs) distinct. Nanophyllous leaves persistent, 4–10 mm long, cordiform. Inflorescences solitary or a few together, 3–20-flowered, laxly to densely corymbiform; peduncle 1.5–7 cm long, pubescent or rarely glabrous; bracts to 0.2 cm long, ovate or lanceolate; lateral branches, if present, to 3 cm long, glabrous or pubescent; pedicels to 2 cm long, pubescent or rarely glabrous. Flowers 5-merous; calyx lobes ca. 1 mm long, stiff, narrowly triangular, acute, pubescent; corolla ca. 5 mm long, cleft to near the base, glabrous on both surfaces, the lobes lanceolate, spreading. Stamens ca. 5 mm long, coherent; anther cells and apical appendages connate; anther cone ovoid, straight; filaments short; sacs opening completely longitudinally(?); apical appendage thin and smooth; connective indistinctly passing over to the thecae, smooth. Style ca. 6 mm long, glabrous with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

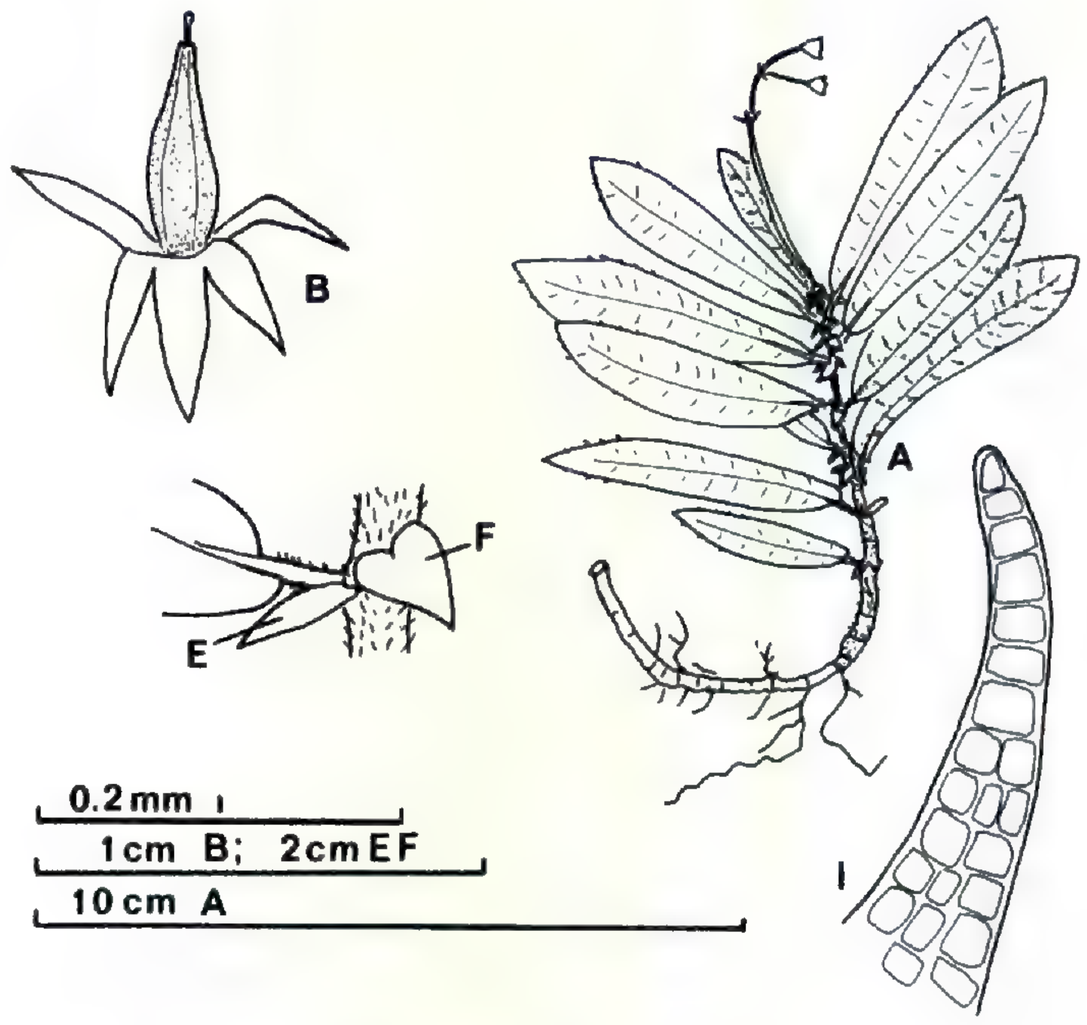

FIGURE 7. *Argostemma densifolium.*—A. Habit.—B. Flower.—E. Stipule.—F. Nanophyllous leaf.—I. Stiff, pluricellular leaf hair. A, E–I from *Sylvester Tong S34346* (K); B from *Nielsen 538* (K).

There are only a few collections of this species, and they are in bad condition. The description of the flowers was prepared from undissected flowers, and so some information is lacking. The scanty information on its habitat indicates that it grows on steep sandstone slopes and on gentle slopes on litter. It was collected at low altitude in southwestern and northeastern parts of Sarawak and in Sabah. I have not managed to find the locality "Bongaya," but according to Steenis-Kruseman (1950), Ridley visited the Kudat, Sandakan, and Lubak Bay in 1897, so it must be somewhere in this area. Ridley (1927) described two varieties of this species. I agree with him that the two populations are different. The southwestern population (Fig. 7A), including the type of *A. densifolium*, has narrow leaves and glabrous inflorescences, while the northeastern population, including the type of var. *latifolium*, has denser foliage with larger, broader leaves and pubescent inflorescences. In this study, however, I have chosen not to deal with infraspecific taxa. On herbarium labels, Bakhuizen f. has treated these taxa as synonyms of *A. ophirense*. *Argostemma ophirense* and its allies are complex, but *A. ophirense* and *A. densifolium* from Borneo are two distinct taxa, in my opinion. *Argostemma densifolium* has a different leaf shape, denser foliage, and long peduncles.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Sabal, 1974, *Sylvester Tong S34346* (K, L, MO); 4th Div., Melinau gorge pathway, 1962, *Burtt & Woods 2214* (E); 7th Div., Gunong Mulu, Melinau gorge, 100 m, 1978, *Nielsen 538* (AAU, K); 200 m, 1978, *Nielsen 445* (AAU).

5. Argostemma ophirense Maingay ex Hook. f., The Flora of British India 3(7): 45. 1880. TYPE: Malacca. Mt. Ophir, 1867–1868, *Maingay 2578* (holotype, K). Figure 8.

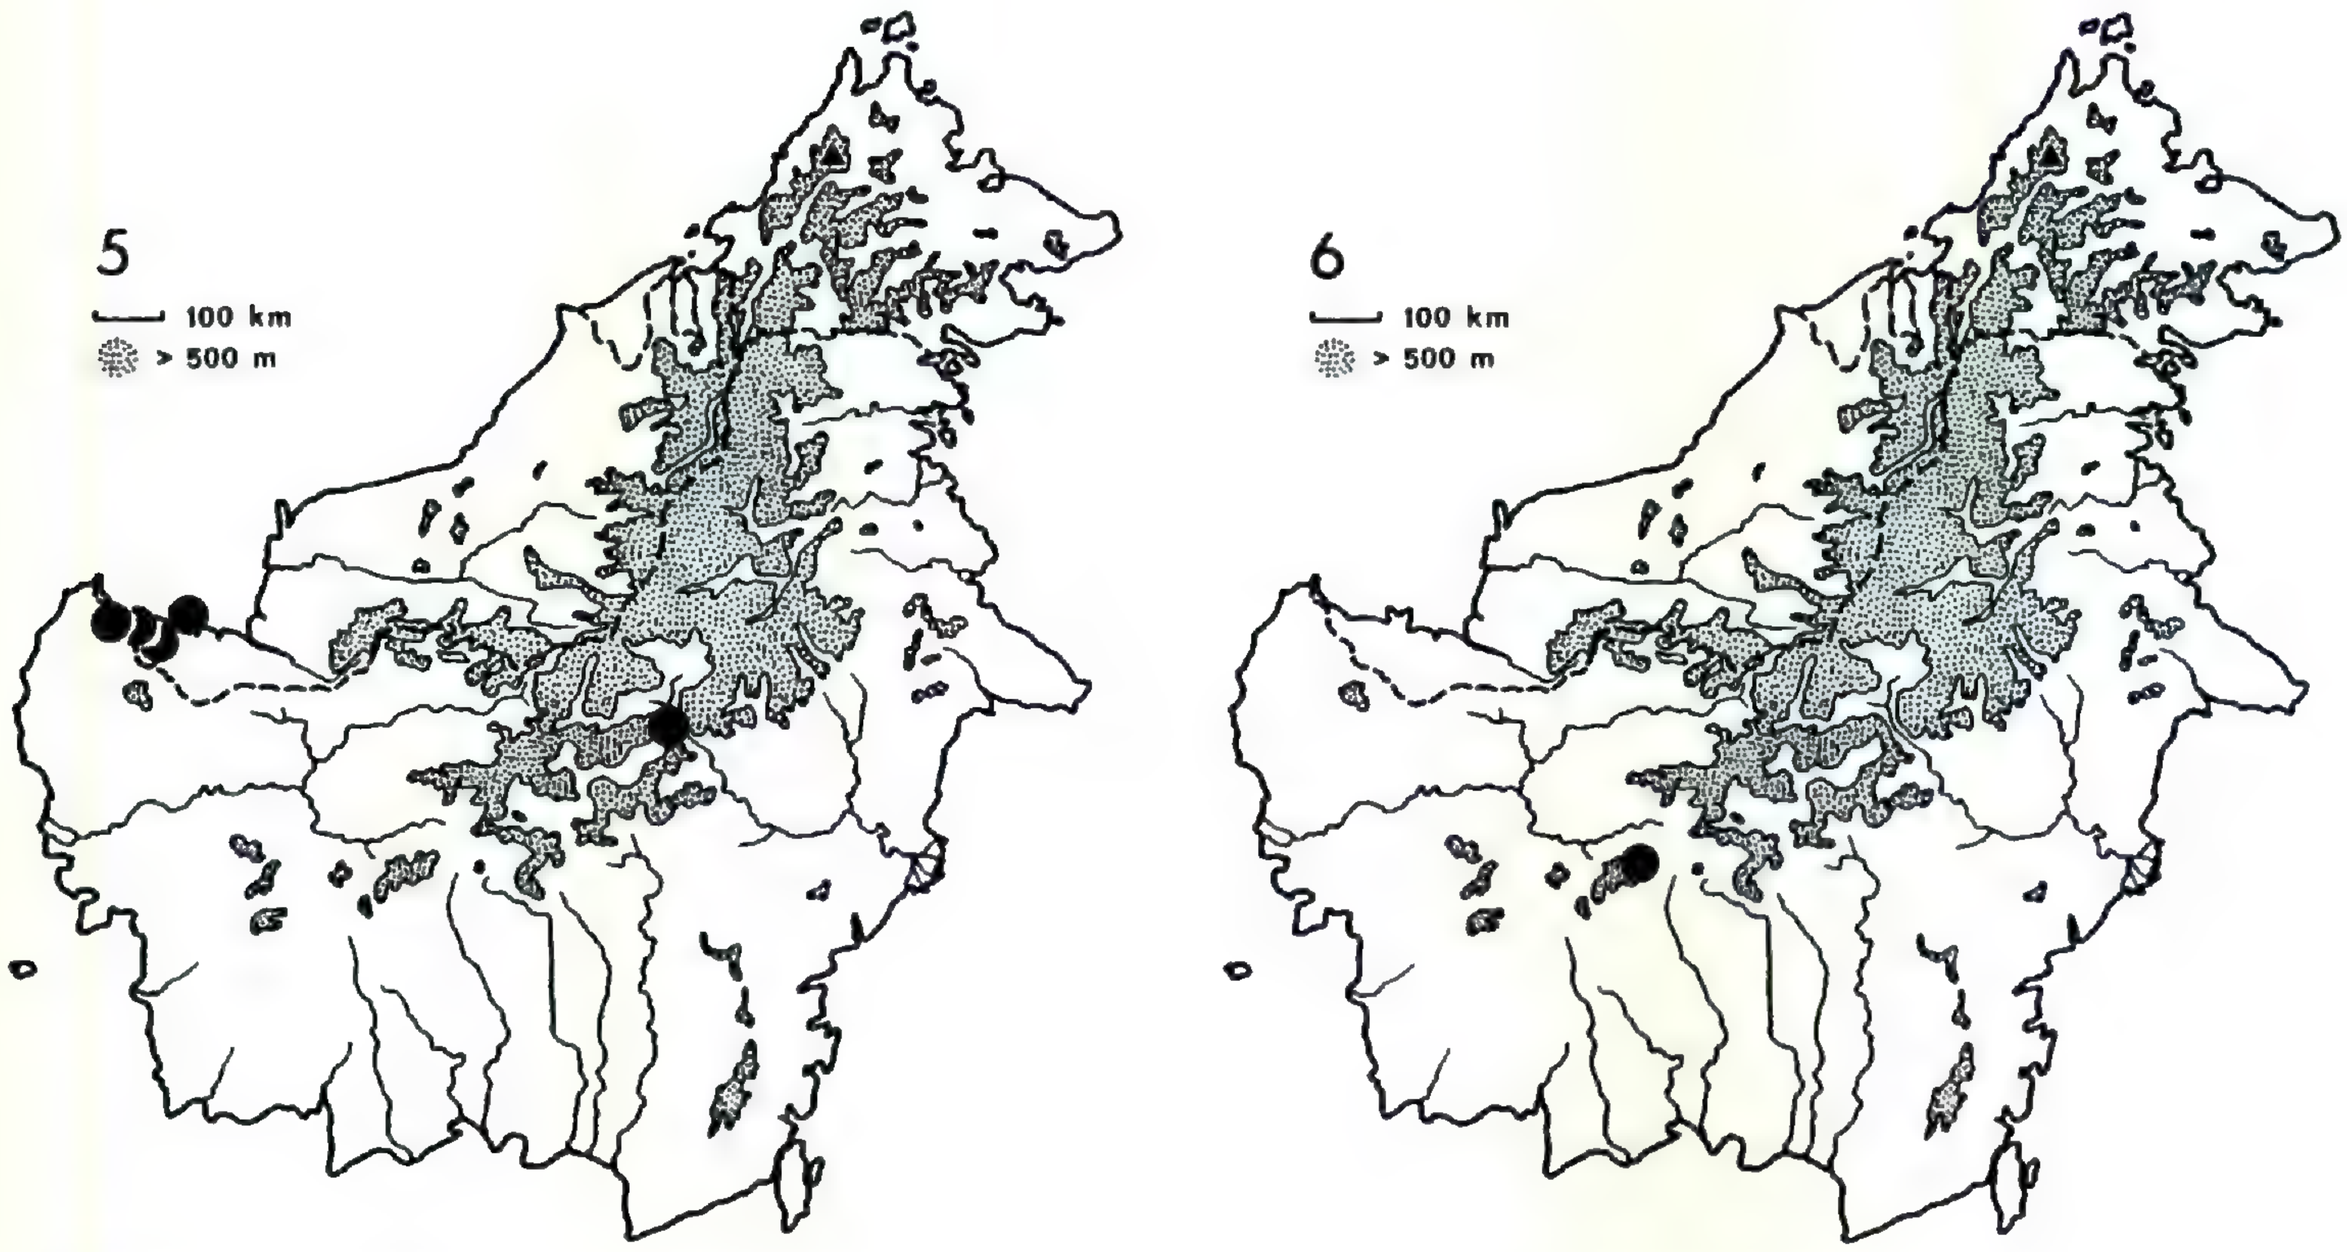
A. salicifolium Ridley, J. Straits Branch Roy. Asiat. Soc. 61: 14. 1912. TYPE: Mt. Matang, *Ridley 11751* (holotype, SING; isotypes, BM, K).

Erect, anisophyllous herb. Stem 7–30 cm long, slightly branched or unbranched, pubescent; internodes 3–15 mm. Leaves opposite, very unequal; stipules persistent, 3–5 mm long, ovate to lanceolate or oblanceolate, acute to obtuse; larger leaves of the anisophyllous pairs with pubescent petioles, to 5 mm long; lamina 5–16 × 0.4–3 cm, lanceolate to linear, basally cuneate or acute to subcordate and oblique or with the lobes unequal, marginally entire, apically acuminate to narrowly acuminate, herbaceous to coriaceous, with a few stiff pluricellular hairs on the upper surface, pubescent on the veins below; midrib and primary veins (10–20 pairs) distinct, at least below. Nanophyllous leaves persistent, 3–5 mm long, cordiform. Inflorescences solitary or a few together, 7–18-flowered, laxly corymbiform, glabrous; peduncle 1–3 cm long; bracts to 0.5 cm long, ovate to linear; lateral branches 1–2 cm long; pedicels 0.4–0.7 cm long. Flowers 5-merous; calyx lobes ca. 1 mm long, stiff, narrowly triangular, acute, glabrous; corolla 4–5 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate, acute, spreading. Stamens 4–6 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 4–7.5 mm long, glabrous, with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

When Ridley (1912) described *A. salicifolium* he stated that the specimens are preserved in the Singapore Gardens Herbarium. Bakhuizen f. indicated, on the herbarium label, the K specimen as the type (= holotype). The SING specimen must be treated as the holotype and the K specimen as an isotype, as Ridley (1912) said that the specimens are preserved in SING.

Argostemma ophirense grows on ground or on rocks in forest from 50 to 1,300 m; most collections are from under 1,000 m.

There is little morphological variation in this species except for variation in leaf width and distinctness of foliar veins. It is characterized by indumentum on the stems, petioles, and veins beneath. The leaves are generally lanceolate with oblique bases. The cordiform nanophyllous leaves



MAPS 5, 6. Distributions in Borneo.—5. *Argostemma ophirense.*—6. *A. anisophyllum.*

and stipules are persistent. The inflorescences are lax cymes. The type specimens of *A. salicifolium*, probably collected from near the summit of Mt. Matang, have very narrow leaves with indistinct primary veins on the upper side. The specimens from Kalimantan have more obovate leaves.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Berumput, 1954, *Brooke 8670* (L); 3,000 ft., 1962, *Burtt & Woods 2762* (E, SAR); 1st Div., Mt. Erect, anisophyllous herb. Stem 10–30 cm long, slightly branched or unbranched, glabrous or glabrate; internodes 5–25 mm. Leaves opposite, very unequal; stipules persistent, 4–5 mm long, broadly ovate to lanceolate, acute at apex; larger leaves of the anisophyllous pairs with glabrous petioles 3–7 mm long; lamina 2–6.2 × 1.2–2.2 cm long, obovate to oblanceolate, basally acute to attenuate and oblique, marginally entire, apically acuminate, herbaceous to membranaceous, with a few stiff pluricellular hairs on the upper surface, glabrous below; midrib and primary veins (6–10 pairs) distinct. Nanophyllous leaves persistent, 2–4 mm long, cordiform. Inflorescences solitary, 1–5-flowered, laxly corymbiform, glabrous; peduncle 2–2.8 cm long; lateral branches 1–1.5 cm long; bracts ca. 0.1 cm long, lanceolate or triangular; pedicels 1–2.2 cm long. Flowers 5-merous; calyx lobes ca. 1 mm long, stiff, narrowly triangular, acute, glabrous; corolla 8–9 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate to broadly ovate, spreading. Stamens 9–11 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone narrowly ovoid or ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 10–12 mm long, glabrous, with a slightly capitate stigma, exserted. Fruit without furrows or ribs.

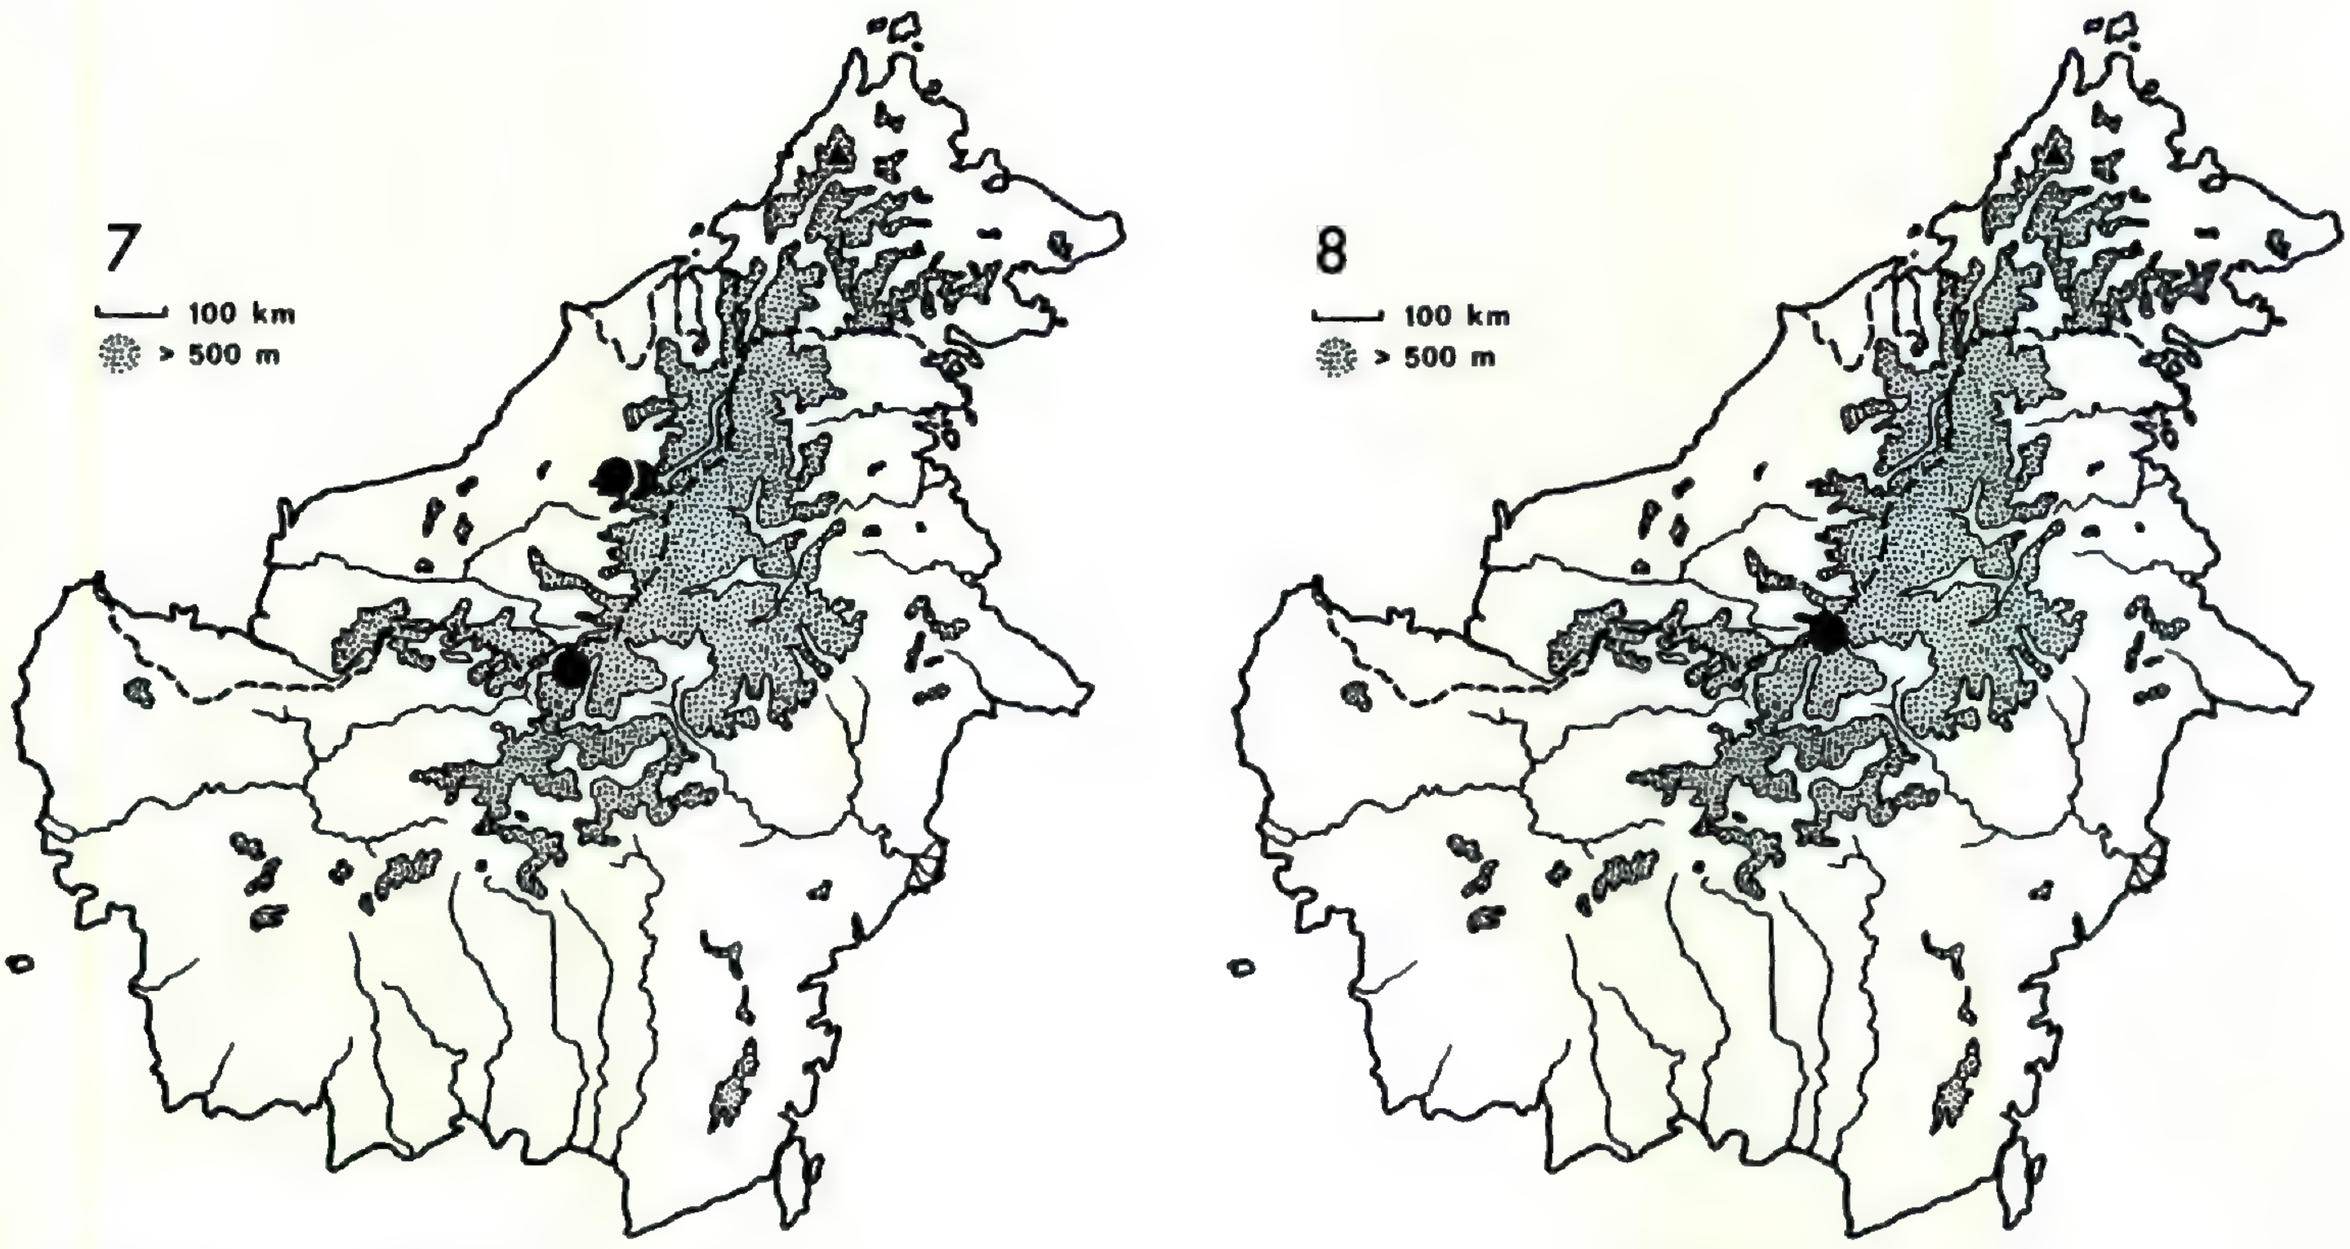
Argostemma anisophyllum grows from 1,250 to 1,400 m at Bukit Raja.

It has been treated as a synonym of *A. ophirense* by Bakhuizen f. on herbarium labels. *Argostemma anisophyllum* has fewer hairs on the stems, much smaller and thinner leaves, longer peduncles and pedicels, and much larger flowers.

Additional specimen examined. BORNEO. KALIMANTAN: Bukit Raja, 1,400 m, 1924, *Winkler 950* (HBG).

7. Argostemma dulitense Merr., Sarawak Mus. J. 3: 554. 1928. TYPE: Borneo. Sarawak: Mt. Dulit, 1,200–1,500 m, 1923, *Mjöberg 8* (holotype, UC). Figure 10.

Erect anisophyllous herb. Stem 10–40 cm long, slightly branched or unbranched, densely pubescent; internodes to 8 mm. Leaves opposite, very unequal; stipules persistent, 2–4 mm long, broadly ovate, acute at apex; larger leaves of the aniso-



MAPS 7, 8. Distributions in Borneo.—7. *Argostemma dulitense.*—8. *A. apiculatum.*

phyllous pairs with glabrous petioles ca. 3 mm long; lamina 2–6 × 0.4–1.5 cm, lanceolate or narrowly elliptic to obovate, basally cuneate to attenuate and with the lobes equal, marginally entire, apically acute to acuminate, coriaceous, glabrous on both surfaces; midrib distinct, primary veins generally obscure. Nanophyllous leaves persistent, ca. 5 mm long, ovate. Inflorescences solitary or a few together, 1–3-flowered, glabrous; peduncle 1–2.5 cm long; bracts to 0.3 cm long, ovate to triangular or lanceolate; pedicels 1–2.7 cm long. Flowers 5-merous; calyx lobes ca. 2 mm long, stiff, narrowly triangular, glabrous. Corolla 9–12 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate to lanceolate, spreading. Stamens ca. 7 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid or narrowly so, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style ca. 8 mm long, glabrous with a scarcely widened stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma dulitense grows in shady places on tree trunks or on rocks near waterfalls in moss and heath forests.

It is characterized by its glossy dark green upper leaf surfaces, pale lower leaf surfaces and very firm leaf texture. The stems are covered by appressed hairs; otherwise it is glabrous. The corolla is large and rotate with green spots at the base, and the anther cone is high. The specimens from Kalimantan have distinct primary veins, while the Sarawak specimens have obscure veins.

Additional specimens examined. BORNEO. Argostemma burttii simile sed planta glabra, lobis corollae apiculatis differt.

Erect, anisophyllous, glabrous herb. Stem 2–30 cm, unbranched; internodes 6–16 mm. Leaves opposite, very unequal; stipules persistent, 5–7 mm long, ovate to cordiform, acute at apex; larger leaves of the anisophyllous pairs with petioles 3–5 mm long, the lamina 3–8.5 × 0.8–1.9 cm, narrowly elliptic, basally cuneate to attenuate with

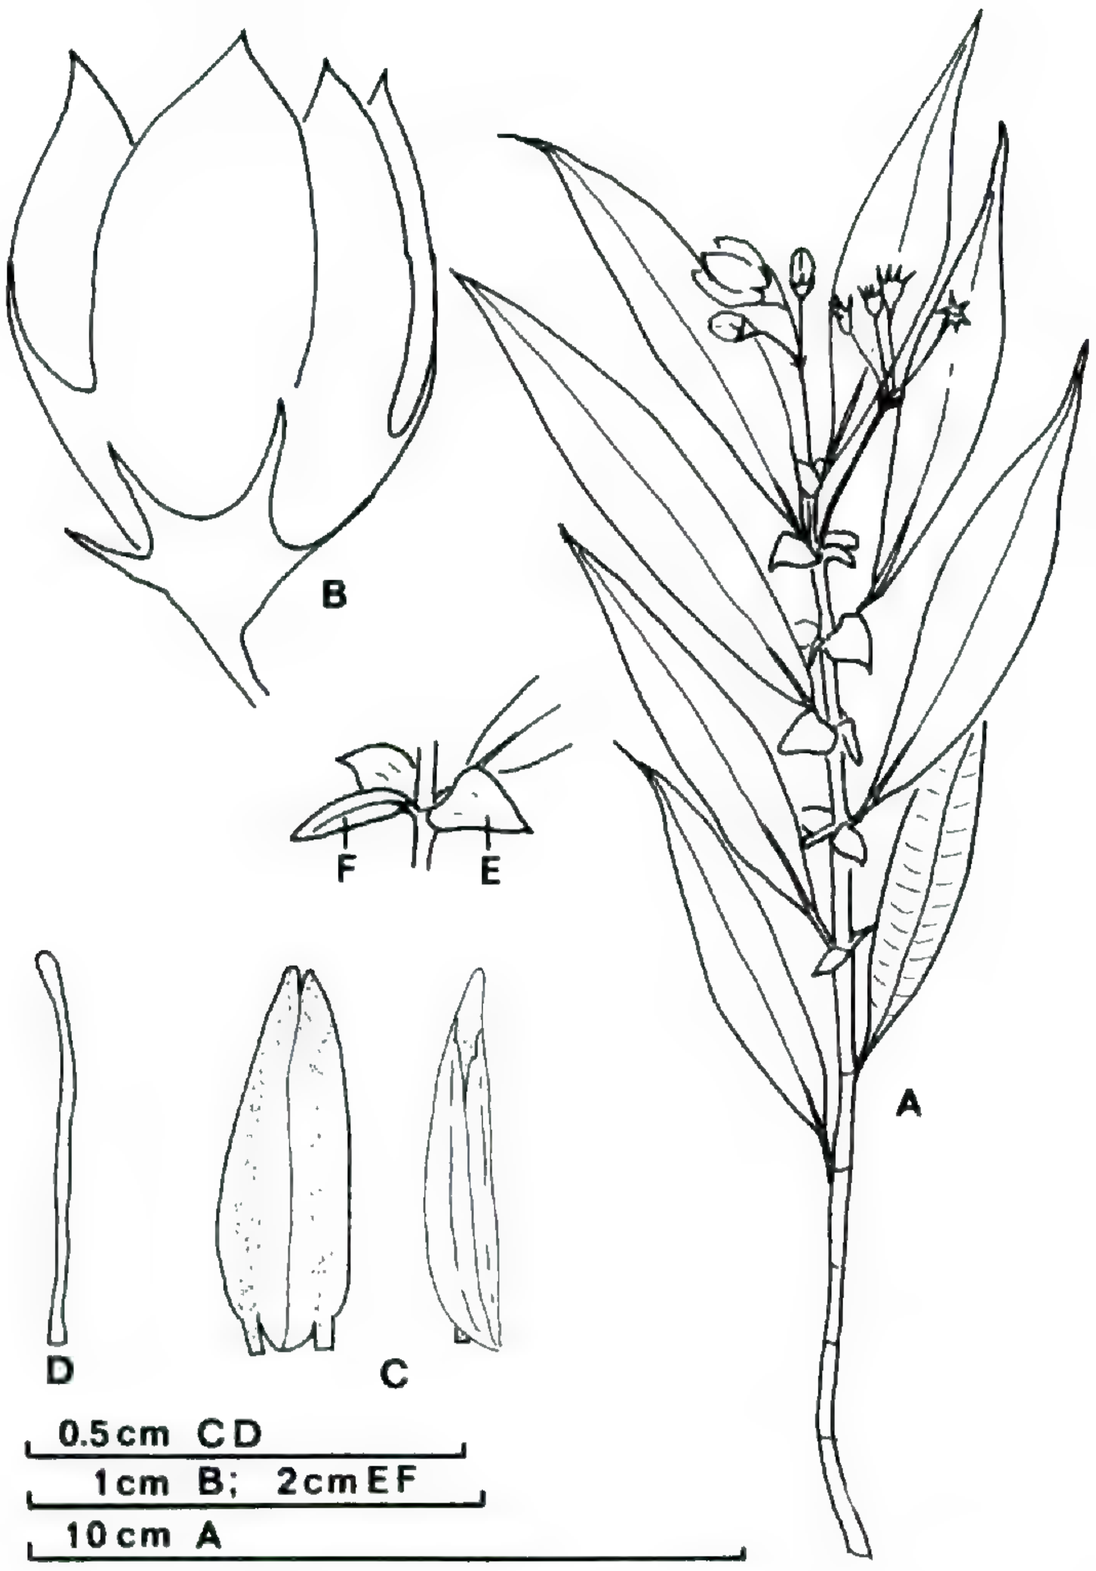

FIGURE 11. *Argostemma apiculatum.*—A. Flowering branch.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf. From *Anderson & Ilias Paie S28657* (K).

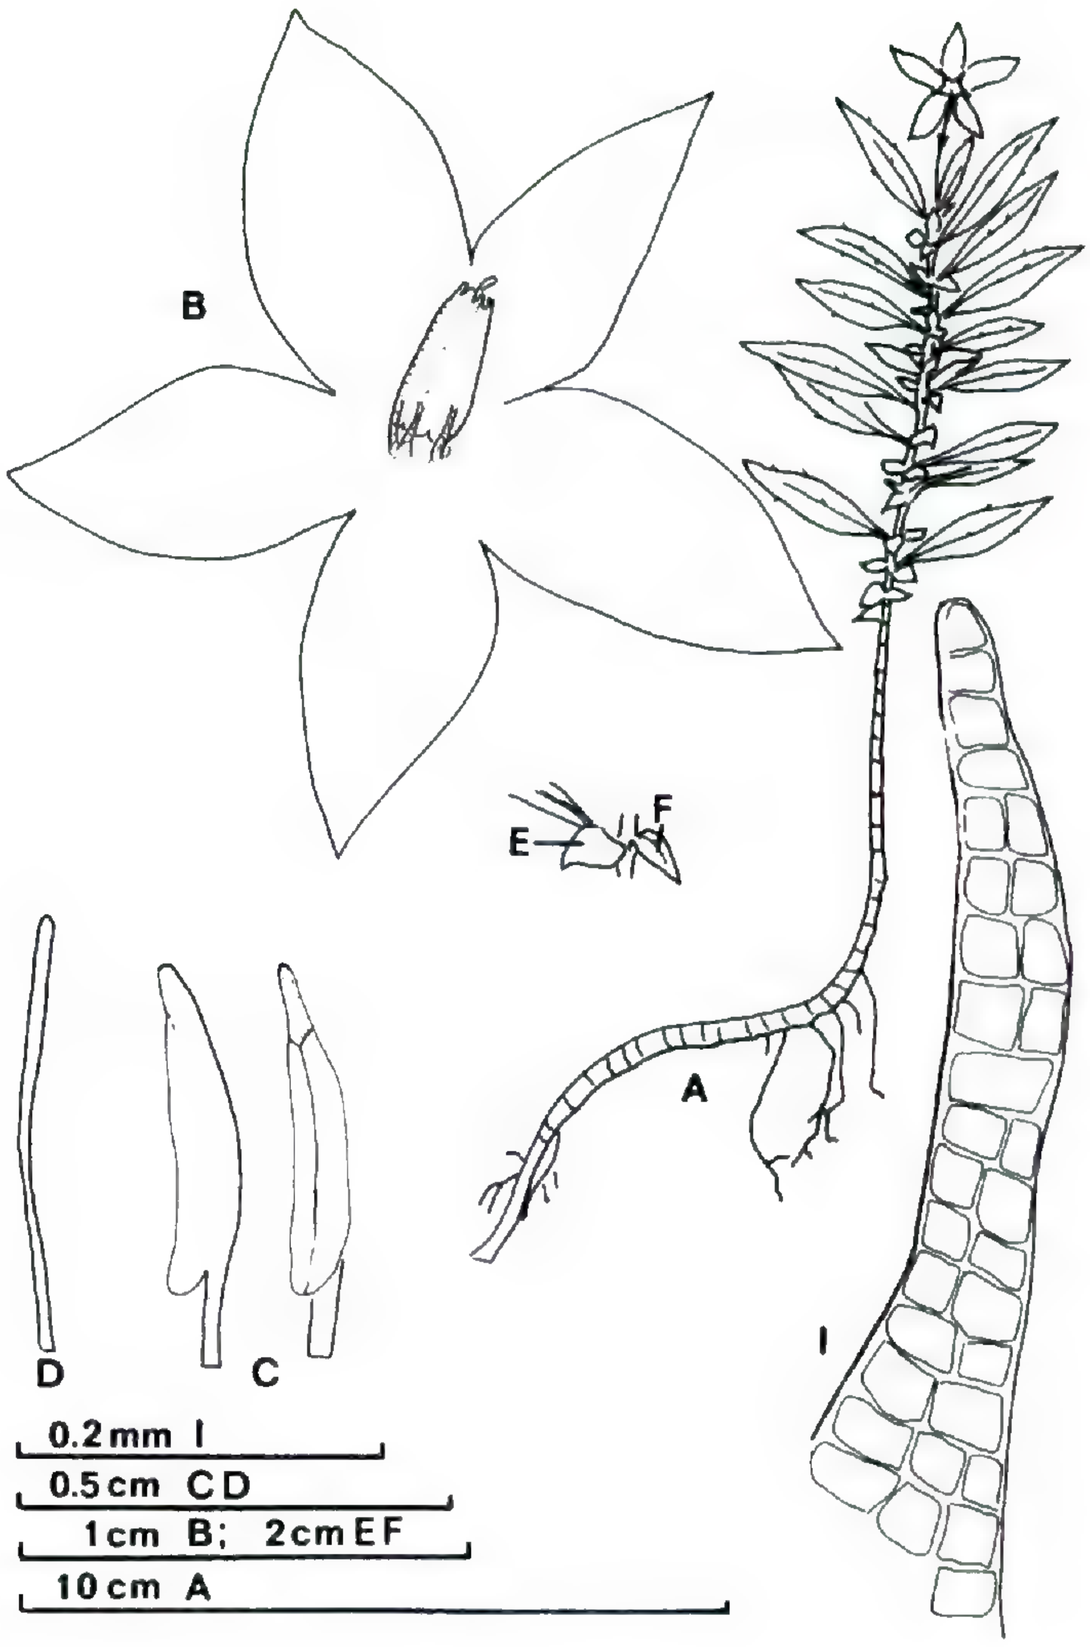

FIGURE 12. *Argostemma burttii.*—A. Habit.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—I. Stiff, pluricellular leaf hair. From *Burtt & Martin 4986* (E).

the lobes equal, marginally entire, apically acuminate, herbaceous to membranaceous; midrib distinct, the primary veins (10–16 pairs) obscure. Nanophyllous leaves persistent, 5–6 mm long, elliptic to lanceolate. Inflorescences 1–4-flowered, laxly corymbiform, solitary or a few together; peduncle 1.5–2 cm; bracts to 0.5 cm long, lanceolate; pedicels to 0.8 mm. Flowers 5-merous; calyx lobes ca. 3 mm long, stiff, narrowly triangular, acute, glabrous; corolla 10–12 mm long, cleft to near the base; lobes ovate to broadly so, pointed, spreading. Stamens 4.5–5 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage less than ¼ the anther length, thin and smooth; connective indistinctly passing over the thecae, smooth. Style ca. 5 mm long, glabrous, with a scarcely widened stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma apiculatum was collected once at Bukit Tibang, on igneous soil at 1,600 m in mossy forest.

It is a glabrous plant with large, broad, pointed corolla lobes. The apical appendages of the anthers are short. It is similar to *A. burttii* because of its large corollas and the short apical appendages. *Argostemma apiculatum* differs from that species by its apiculate corolla lobes and erect glabrous habit.

9. Argostemma burttii B. Bremer, sp. nov.
TYPE: Borneo. Sarawak: SE of Hose Mts., above Ulu Melinau Falls, ca. 4,000 ft., 1967, *Burtt & Martin 4986* (holotype, E). Figure 12.

Herba repens vel suberecta, inflorescentiis floribus solitariis paucisve. Folia opposita, illis parium inaequalissimis, serrulata. Inflorescentia monochasialis, floribus grandibus. unequal; stipules 2–4 mm long, broadly ovate to cordiform, acute at apex. Larger leaves of the anisophyllous pairs with glabrous petioles 1–3 mm long; lamina 1–3.5 × 0.4–0.9 cm, narrowly elliptic, basally cuneate to attenuate with the lobes equal, marginally serrulate, apically acuminate, herbaceous to membranaceous, glabrous on both surfaces but with 3 or 5 rows of stiff pluricellular hairs on the upper surface; midrib distinct, the primary veins obscure. Nanophyllous leaves persistent, to 4 mm long, ovate to lanceolate. Inflorescences 1–2-flowered, monochasial, solitary or a few together; peduncle 1–2 cm, glabrous; bracts to 0.2 cm long, lanceolate to linear; pedicels 0.7–1.5 cm, glabrous. Flowers 5-merous; calyx lobes ca. 1.5 mm long, stiff, triangular to narrowly triangular, acute, glabrous; corolla 9–12 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate, spreading. Stamens 4–5 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage less than ¼ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style ca. 5 mm long, glabrous, with a scarcely widened stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma burttii was found growing at bases of trees among mosses at ca. 1,300 m. It is a local endemic species from the Hose Mountains. Mr. B. L. Burtt has collected it at three different places. It is a beautiful little plant with very large flowers. The corolla is open and flat with green spots at the center, and the anther cone is cream-colored. The border between the filaments and the thecae is indistinct, as in, for example, *A. apiculatum*, *A. rupestre*, and *A. geesinkii*. With the last two it also shares the character of three or five rows of stiff, pluricellular hairs on the upper leaf surface. *Argostemma burtii* is most similar to *A. apiculatum*, both having large corollas and short apical appendages, but *A. burtii* differs by having serrulate leaves and creeping or suberect habit.

Additional specimens examined. BORNEO. SARAWAK: 7th Div., S Hose Mts., W of Bukit Sanpandai, 1980, *Burtt 12750* (E); E of Bukit Sanpandai, 4,500 ft., 1980, *Burtt 12817* (E).

10. Argostemma rupestre Ridley, J. Bot. 65: 41. 1927. TYPE: Borneo. On the hill near Matang, *Haviland 1031* (holotype, K; isotypes, SAR, SING). Figure 13.

Creeping or suberect, anisophyllous herb. Stem 3–14 cm, generally unbranched, glabrous or with a few hairs; internodes very short to 7 mm. Leaves opposite, very unequal; stipules persistent, 2–7 mm long, ovate to lanceolate, acute at apex; larger leaves of the anisophyllous pairs with glabrous petioles to 5 mm long; lamina 1.3–5.5 × 0.2–1.8 cm, narrowly elliptic to lanceolate or oblanceolate, rarely elliptic or linear; basally cuneate to attenuate with the lobes equal; marginally serrulate, apically acuminate; herbaceous to membranaceous, gla-

brous on both surfaces except for 3 or 5 rows of stiff pluricellular hairs above; midrib distinct, the primary veins obscure. Nanophyllous leaves persistent, 2–10 mm long, ovate to elliptic or lanceolate. Inflorescences 1–3(–5)-flowered, laxly corymbiform, solitary or a few together; peduncle 1–3 cm, glabrous or pubescent; bracts 0.1–0.3 cm long, lanceolate; pedicels 0.5–1.5 cm, glabrous or pubescent. Flowers 5-merous; calyx lobes ca. 1 mm long, stiff, triangular to narrowly triangular, acute, glabrous; corolla 4–7 mm long, cleft to near the base; lobes lanceolate, acute to acuminate, erect-spreading. Stamens 5–7 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 6–8 mm long, glabrous, with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma rupestre is a small herb growing on wet sandstone boulders or other wet places in or near streams or waterfalls, chiefly among mosses. It occurs from low altitudes up to ca. 1,500 m in mossy forests.

This anisophyllous herb has glabrous leaves except for three or five rows of stiff pluricellular hairs on the midrib and along the margins. The marginal hairs make the leaves serrulate. The lower surface of the leaves is pale. The stipules and nanophyllous leaves are similar in shape. The corolla is cleft to near the base into narrow and erect-spreading lobes. The anther cone is high with a pale yellow color near the base and whitish at the apex. The inflorescences are lax cymes with one to five flowers. The peduncles and pedicels are narrow and generally glabrous. The specimens from Bako are all pubescent on the peduncles, pedicels, and ovaries and have somewhat broader corolla lobes. There are two collections from different areas (*Brooke 9131* and *Richards 2455*) with very narrow leaves; both were collected in or near streams and may be ecotypes. *Clemens 21737* came from an uncertain locality: on the herbarium label is written "Gat, Upper Rajang River," while on the attached field label both "Gat" and "Mt. Matang" are written. This plant has pubescent pedicels, as does the Bako population.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., N slopes of Mt. Penrissen, 1,000–1,100 m, 1958, *Jacobs 5065* (B, G, K, L, SAR, UC); 1st Div., Bako, on slopes just N of the office, 1979, *Bremer 1675* (S, SAR); at Serai path S of the office, 1979, *Bremer 1687* (S, SAR); Telok Asam, 100 m, 1956, *Purseglove 5095* (K, L, NY, SAR, SING); Telok Asam, 100 m, 1957, *Purseglove 5534* (K, L, SAR, SING); 1st Div., Sabal, 350 m, 1979, *Bremer 1665* (S, SAR); 3rd Div., Teneong, 1954, *Brooke 9131* (BM, L); 4th Div., Ulu Mersing, Ulu Anap, 100 m, 1963, *Ashton S17691* (K, L, SAR); 4th Div., Mt. 11. Argostemma geesinkii B. Bremer, sp. nov. TYPE: Borneo. Kalimantan Timur, between Papadi and Pamilau, 1,400 m, 1981, *Geesink 9272* (holotype, L). Figure 14.

Herba pusilla, repens, inflorescentiis floribus solitariis aut duobus. Folia opposita, illis parium inaequalissimis, serratula vel integra. Inflorescentia monochasialis, floribus mediocribus. Lobi calycis, rigidi, anguste triangulares, acuti. Lobi corollae erecto-patentes, in exsiccatis subrosei. Antherae et appendices apicales connatae praeter partem apicalissimam. Appendix apicalis ⅓ longitudinem antherae aequans, tenuis, laevis. Connectivum indistinctum. Stylus glaber stigmate leviter capitato.

Argostemma rupestre simile sed planta pusilla, lobis corollae latis erecto-patentibus differt.

Small, creeping, anisophyllous herb. Stem 2–20 cm, slightly branched or unbranched, glabrous; internodes very short to 5 mm. Leaves opposite, very unequal; stipules 2–4 mm long, ovate to cordiform, acute to obtuse at apex; larger leaves of the anisophyllous pairs with glabrous petioles 1–2 mm long; lamina 2.5–7 × 0.6–1.5 cm, elliptic to obovate, basally cuneate to attenuate with the lobes equal, marginally serrulate or entire, apically acute to shortly acuminate or rarely obtuse, membranaceous, glabrous on both surfaces but with 3 or 5 rows of stiff pluricellular hairs on the upper surface; midrib distinct, the primary veins generally obscure. Nanophyllous leaves persistent, 2–5 mm long, ovate to elliptic, acute. Inflorescences 1–2-flowered, monochasial, solitary or a few together; peduncle 0.2–1 cm, glabrous; bracts ca. 1 mm long, lanceolate to triangular; pedicels 0.5–1 cm, glabrous. Flowers 5-merous; calyx lobes ca. 1 mm long, stiff, narrowly triangular, acute, glabrous; corolla 5–7 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate to broadly ovate, acute, erect-spreading. Stamens 4–5 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 4–5 mm long, glabrous, with a slightly capitate stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma geesinkii grows on tree trunks and on boulders among mosses, from 950 to 1,500 m. A few collections are from sandstone.

Argostemma geesinkii is a very small creeping species with small anisophyllous leaves and cordiform stipules. It is glabrous except for the stiff pluricellular hairs in three or five rows on the upper leaf surfaces. The flowers are generally solitary on thin pedicels. The corolla lobes are broad and often become pinkish in the press. All specimens except *Endert 3916* are very similar. This aberrant spec-

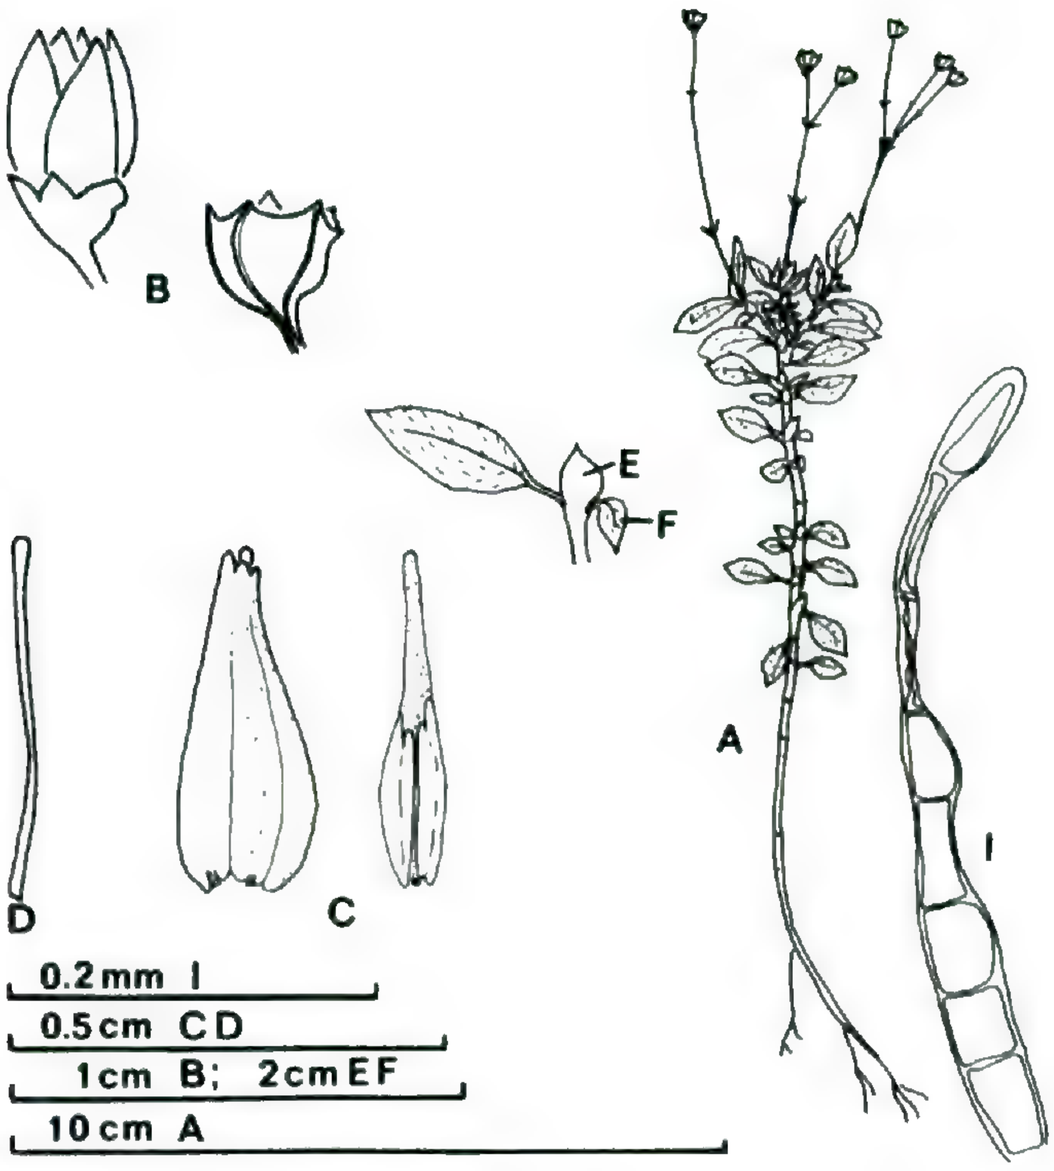

FIGURE 15. *Argostemma gaharuense*.—A. Habit.—B. Flower and fruit.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—I. Hair from upper surface of leaf. From *Burtt 2655* (E).

imen lacks stiff hairs and has thicker leaves and prominent primary veins, but there are no floral differences between it and the other collections of *A. geesinkii*. There is another specimen from the same area (*Endert 3800*) that does not deviate from the others. Perhaps *Endert 3916* is a different taxon.

Additional specimens examined. BORNEO. SABAH: Kimanis road, Keningau, 4,400 ft., 1979, *Collenette 4179* (E). 12. Argostemma gaharuense B. Bremer, sp. nov. TYPE: Borneo. Sarawak: 1st Div., Bukit Gaharu, 2,000 ft., 1962, *Burtt 2655* (holotype, E). Figure 15.

Herba pusilla, ramosa, inflorescentiis floribus solitariis vel paucis. Folia opposita, illis parium inaequalissimis, pubescentia. Inflorescentia corymbosa, floribus pusillis. Lobi calycis triangulares, acuti. Lobi corallae reflexi. Antherae et appendices apicales connatae praeter partem apicalissimam. Appendix apicalis ½ longitudinem antherae aequans, tenuis, laevis. Connectivum indistinctum. Stylus glaber, stigmate vix dilatato.

Argostemma rupestre simile sed planta pubescens, ramosa, lobis corollae reflexis, fructu costato differt.

Small, creeping(?) herb. Stem to 20 cm, branched, glabrous; internodes very short to 4 mm. Leaves opposite, very unequal; stipules 2–3 mm long, ovate to cordiform, acute at apex; larger leaves of the anisophyllous pairs with glabrous petioles 1–2 mm long; lamina 0.4–0.6 × 0.2–0.4 mm, elliptic to narrowly so, basally cuneate to attenuate with the lobes equal, marginally entire, apically acute, coriaceous, pubescent above and glabrous below; midrib distinct but without primary veins. Nanophyllous leaves persistent, 2–3 mm long, ovate to elliptic, acute. Inflorescences 1–6-flowered, laxly corymbiform, many together; peduncle 1.4–2.8 cm, glabrous; bracts ca. 1 mm long, lanceolate; pedicels 0.5–1.4 cm, glabrous. Flowers 5-merous; calyx lobes ca. 1 mm long, triangular, acute, glabrous; corolla ca. 4 mm long, cleft to near the base, glabrous on both surfaces; lobes ovate, acute, reflexed. Stamens 3.5–4 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoidal, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ½ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style ca. 4.5 mm long, glabrous, with a scarcely widened stigma, shortly exserted. Fruit with 5 distinct ribs corresponding to the middle vascular strands of the calyx lobes.

Argostemma gaharuense was collected by Burtt at 660 m at Bukit Gaharu. Its habit is not given on the herbarium label.

On the label of the type specimen is written: "Leaves dark green above, white below. Corolla white, lobes strongly reflexed. Base of anther cone green, tips white." It is a small, easily recognized plant. The leaves are dark and pubescent on the upper surfaces, and below they are white and glabrous. The stems are distinctly branched distally with many apical inflorescences, each with one to six flowers in lax cymes. The vascular strand to each calyx lobe becomes a distinct rib, making the fruit five-ribbed. The habit is similar to that of *A. rupestre*, *A. geesinkii*, and *A. burttii*, but *A. gaharuense* differs from these by having monoseriate leaf hairs, branched stems, and reflexed corolla lobes. The leaf and stipule shapes are the same as those of *A. geesinkii*. The specimen from Gunong Apeng has narrower leaves than the type, and there is only one inflorescence with two flowers. However, it has reflexed corolla lobes and the same kind of indumentum.

13. Argostemma hameliifolium Wernham in Gibbs, J. Linn. Soc. Bot. 42: 89. 1914. TYPE: British North Borneo. Kinabalu: before Lobang rock, 5,000 ft., 1910, *Gibbs 4101* (holotype, K; isotype, BM). Figure 16.

A. hullettii Ridley, J. Bot. 65: 35. 1927. TYPE: Borneo. Sarawak: Matang, 2,000 ft., 1884, *Hullett 329* (lectotype, SING; Bakh. f. in herb., confirmed here).

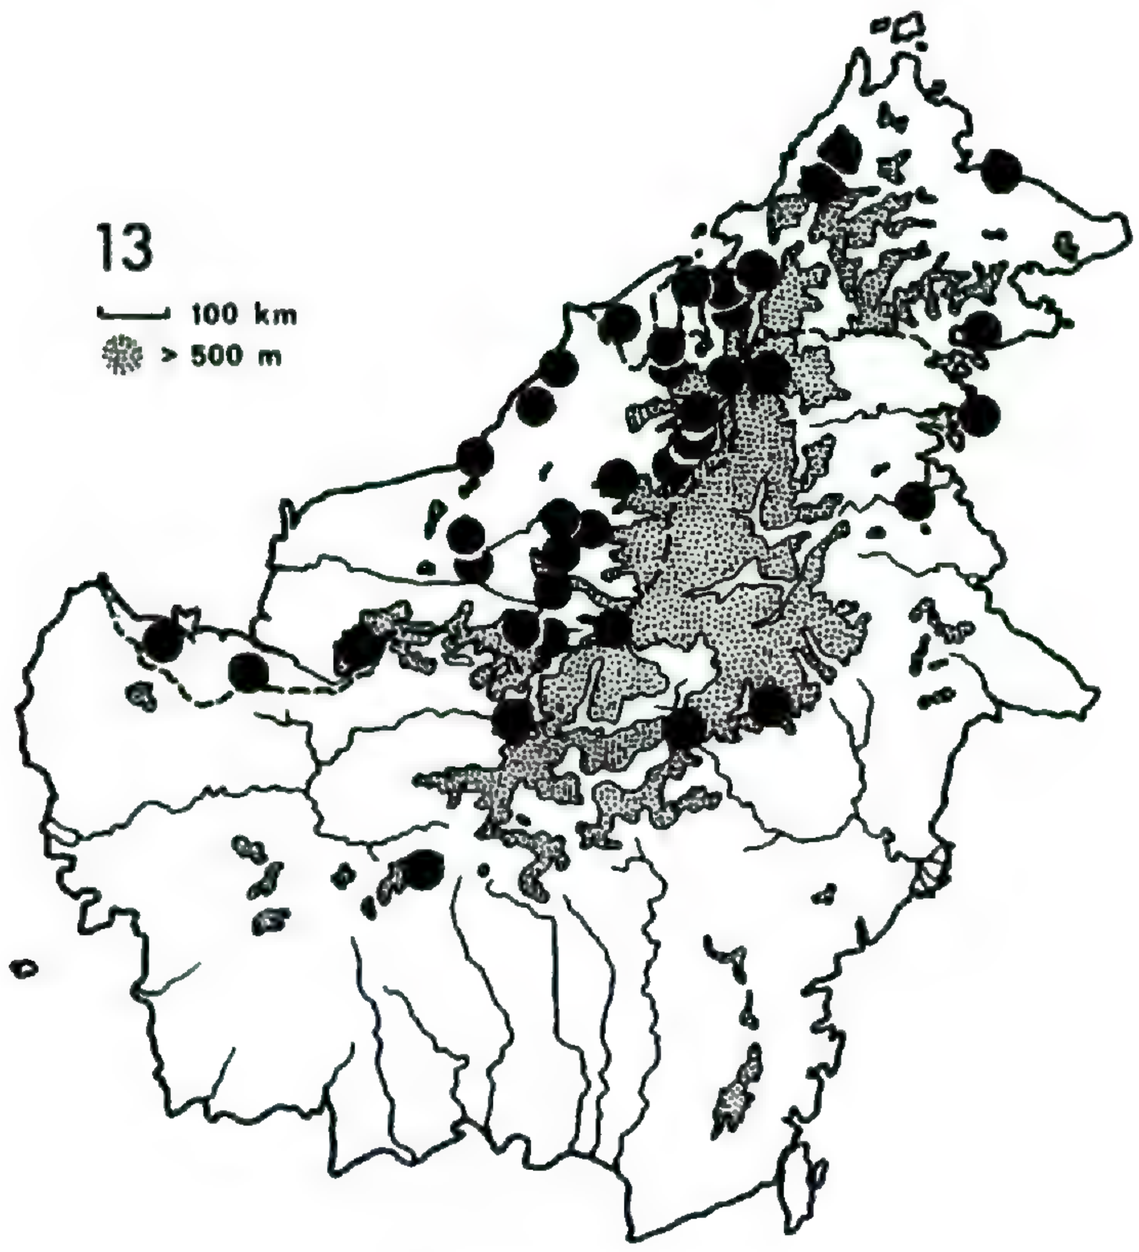
A. isophyllum Merr., Mitt. Inst. Allg. Bot. Hamburg 7: 279. 1937. TYPE: West Borneo: Bukit Raja, 1,400 m, 1924, *Winkler 949* (holotype, HBG; isotype, NY).

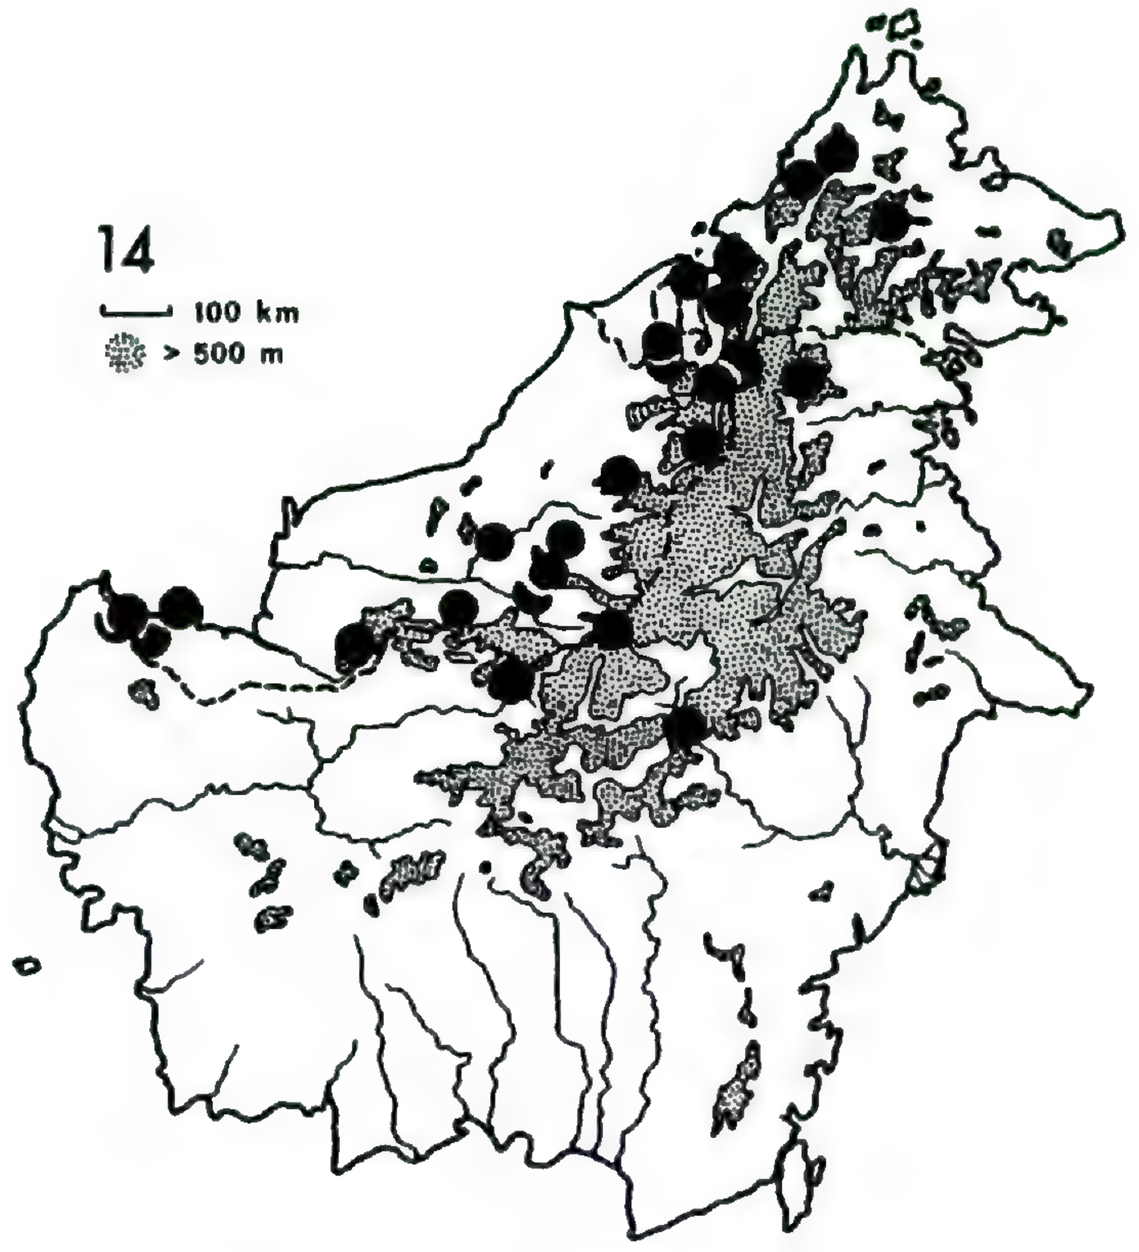
Large, erect, isophyllous herb. Stem 10–100 cm, unbranched, glabrous to pubescent, rarely with corky or papery bark; internodes 10–85 mm. Leaves opposite, equal; stipules deciduous, 5–27 mm long, oblong to lanceolate to ligulate, entire or slightly bifid, acute to acuminate or obtuse at apex; petiole 4–30 mm long, glabrous to pubescent; lamina 5–19 × 1–8.7 cm, oblanceolate or obovate to lanceolate or ovate, basally attenuate to acute or cuneate with the lobes equal, marginally entire, apically acuminate to acute or rarely obtuse, herbaceous, glabrous to finely pubescent above, glabrous to pubescent below; midrib and primary veins (6–12 pairs) distinct. Inflorescences 3–40-flowered, umbelliform and rarely with 2 or 3 scorpioid branches, generally solitary; peduncle 2–7.5 cm, almost glabrous; bracts to 5(–10) mm long, lanceolate to linear; lateral branches, if present, to 3.5 cm long, almost glabrous; pedicels 6–12 mm long, finely pubescent. Flowers 5-merous; calyx lobes 1–1.5 mm long, triangular to ovate, acute, finely pubescent; corolla 4–7 mm long, cleft to near the base, externally glabrous or pubescent, internally glabrous to pubescent; lobes lanceolate, spreading to reflexed. Stamens 3–6 mm long, coherent; anther cells and apical appendages connate except for the free and incurved most apical parts, each of these formed into an open cylinder; anther cone ovoid, straight; filaments generally short, equal, straight or bent; sacs opening completely longitudinally; apical appendage ca. ¼–⅓ the anther length, thin and smooth; connective distinct, generally smooth. Style 4.5–7.5 mm long, pubescent or rarely glabrous, with a capitate stigma, shortly exserted. Fruit without furrows or ribs.

Ridley based *A. hullettii* on three collections, by *Haviland* and by *Hullett*. All are suitable for lectotypification. Bakhuizen f. (in herb.) selected the single *Hullett* specimen in SING, and I follow his choice. The elevation mentioned in the protologue is indicated only on that specimen.

Argostemma hameliifolium is common and is widely collected. It grows from low altitude to 2,000 m. Most collections are from sandstone; a few are from limestone. It grows on boulders or sand in wet places near streams or waterfalls.

Argostemma hameliifolium is part of a big, poorly understood complex, which includes *A. moultonii* (see discussion under that species). Ap-





MAPS 13, 14. Distributions in Borneo.—13. *Argostemma hameliifolium.*—14. *A. moultonii.*

proximately 100 specimens have been referred to *A. hameliifolium*, all large plants with large, equal, opposite leaves and more or less erect stems. The leaves vary in shape and size and in distinctness of nervation. In a few cases the leaves are very broad and obtuse; these are similar in appearance to *A. borragineum*. The stipules, of which only the upper first to third pairs are persistent, are large, ovate to ligulate, and entire or slightly cleft. The flower buds are narrowly ovate in outline. The anther cone is high with short, free apical appendages and generally short filaments. The margins are longer than the central part and incurved so that each apical appendage forms an open cylinder. The style is generally hairy with a distinct capitate and slightly bifid, slightly exserted stigma. In this treatment I maintain *A. hameliifolium* separate from *A. moultonii*. There are many distinguishing characters, though not always constant, and many specimens are impossible to determine with certainty. *Argostemma hameliifolium* is more erect and has larger vegetative organs. Its anthers have short apical appendages and shorter filaments.

A. mjoebergii Merr., Sarawak Mus. J. 3: 534. 1928. TYPE: Borneo. Sarawak: Mt. Poi, 4,500–5,500 ft., 1924, *Mjöberg s.n.* (holotype, UC).

A. murudense Merr., Sarawak Mus. J. 3: 535. 1928. TYPE: Borneo. Sarawak: Mt. Murud, 1,900–2,400 m, 1922, *Mjöberg 82* (holotype, UC; isotype, K).

Creeping to erect, isophyllous herb. Stem 2–40 cm, unbranched or slightly branched, glabrous to densely pubescent, rarely with corky or papery bark; internodes 5–60 mm. Leaves opposite, equal; stipules deciduous, 2–12 mm long, ovate to lanceolate, entire or slightly bifid, obtuse to acuminate at apex; petiole 3–11 mm long, glabrous to pubescent; lamina 1.2–6.5 × (0.2–)0.6–3.1 cm, linear to broadly ovate, basally rounded to attenuate, with the lobes equal or oblique, marginally entire or serrulate, apically obtuse with a short point or acute or acuminate, herbaceous, pubescent on both surfaces to glabrous; midrib distinct, the primary veins (4–7 pairs) distinct to obscure. Inflorescences 1–9-flowered, umbelliform, generally solitary; peduncle (1–)3–8 cm, glabrous; bracts to 5 mm long, ovate to lanceolate; pedicels 0.2–1.2 cm, pubescent. Flowers 5(–6)-merous. Calyx lobes ca. 1 mm long, triangular to ovate, acute, pubescent at least in lower parts. Corolla 3–9(–18) mm long, cleft to near the base, generally glabrous on both surfaces; lobes lanceolate, spreading to reflexed. Stamens 3–6 mm long, coherent; anther cells and apical appendages connate except for the most apical parts, these free and incurved, forming an open cylinder; anther cone ovoid, straight; filaments generally long, equal, straight or bent; sacs opening completely longitudinally; apical appendage ca. ⅓–½ of the anther length, thin and smooth; connective distinct, generally smooth. Style 3.5–6.5 mm long, pubescent or rarely glabrous, with a capitate stigma, shortly exserted. Fruit without furrows or ribs.

Bakhuizen f. (pers. comm. and on herbarium labels) treated *A. parvulum* as a synonym of *A. hameliifolium*; he believed it to be a dwarf form. However, I have found that *A. parvulum* is better accommodated as a synonym of *A. moultonii*.

Argostemma moultonii grows in wet, damp places among mosses on tree trunks, on cliffs, or on sandy or clayey soil, and a few collections are from limestone. It grows from low altitude up to ca. 2,000 m; most specimens are from ca. 1,000 m.

Ridley based *A. moultonii* on two collections by *Moulton*, in K. Both are suitable for lectotypification. Bakhuizen f. (in herb.) selected one of the specimens, *Moulton 6695*, and I follow his choice.

Ridley based *A. velutinum* on three collections, in K, by *Haviland*, *Moulton*, and himself. All are suitable for lectotypification. Bakhuizen f. (in herb.) selected the *Haviland* specimen, and I follow his choice.

Argostemma moultonii and *A. hameliifolium* form a complex in which a number of species have been recognized (see above). This complex is well defined as a group by unique characters: equal, opposite leaves; long, glabrous peduncles; pubescent pedicels; corolla cleft to near the base and with narrow, spreading or reflexed lobes; and connate anthers with distinct apical appendages which are free in the upper part and have margins longer than the central parts and incurved to form an open cylinder. There are at least two species (*A. hameliifolium* and *A. moultonii*) involved in the complex. I cannot recognize more in spite of the fact that this group is the most widely collected in Borneo. There are a few specimens similar in habit to the highly variable species *A. aequifolium* Ridley (1901) from the Malay Peninsula and Sumatra, but this species does not have the unique stamen characters. Specimens similar to the type of *A. hameliifolium*, erect, large plants, are referred to *A. hameliifolium*, but the rest could be separated into several variable groups within *A. moultonii*. There would be many specimens that could not be placed with certainty.

Argostemma moultonii needs further study. I have dealt with it in a manner similar to Dr. Bakhuizen f. (pers. comm.). *Argostemma moultonii* generally can be characterized and separated from *A. hameliifolium* by having a smaller, creeping habit, generally longer internodes, smaller stipules, and anthers with long filaments and long apical appendages. Within *A. moultonii* at least six local populations with distinct morphological characters can be identified. From some localities different populations are found without continuous variation between them. Characters separating these populations are indumentum of the stems, leaves, and floral parts and the shape, texture, and nervation of the leaves. The following examples illustrate this. At the summit of Mt. Matang the plants (including the type of *A. velutinum*) have ovate leaves with acuminate apices, distinct primary veins, and long petioles, and the plants are covered by long hairs. Close to that locality, at Lundu and Berumput, the collections (including the type of *A. mjoebergii*) are similar in habit but less pubescent and have shorter petioles and less distinct veins. At Gunong Murud several different populations occur. One is

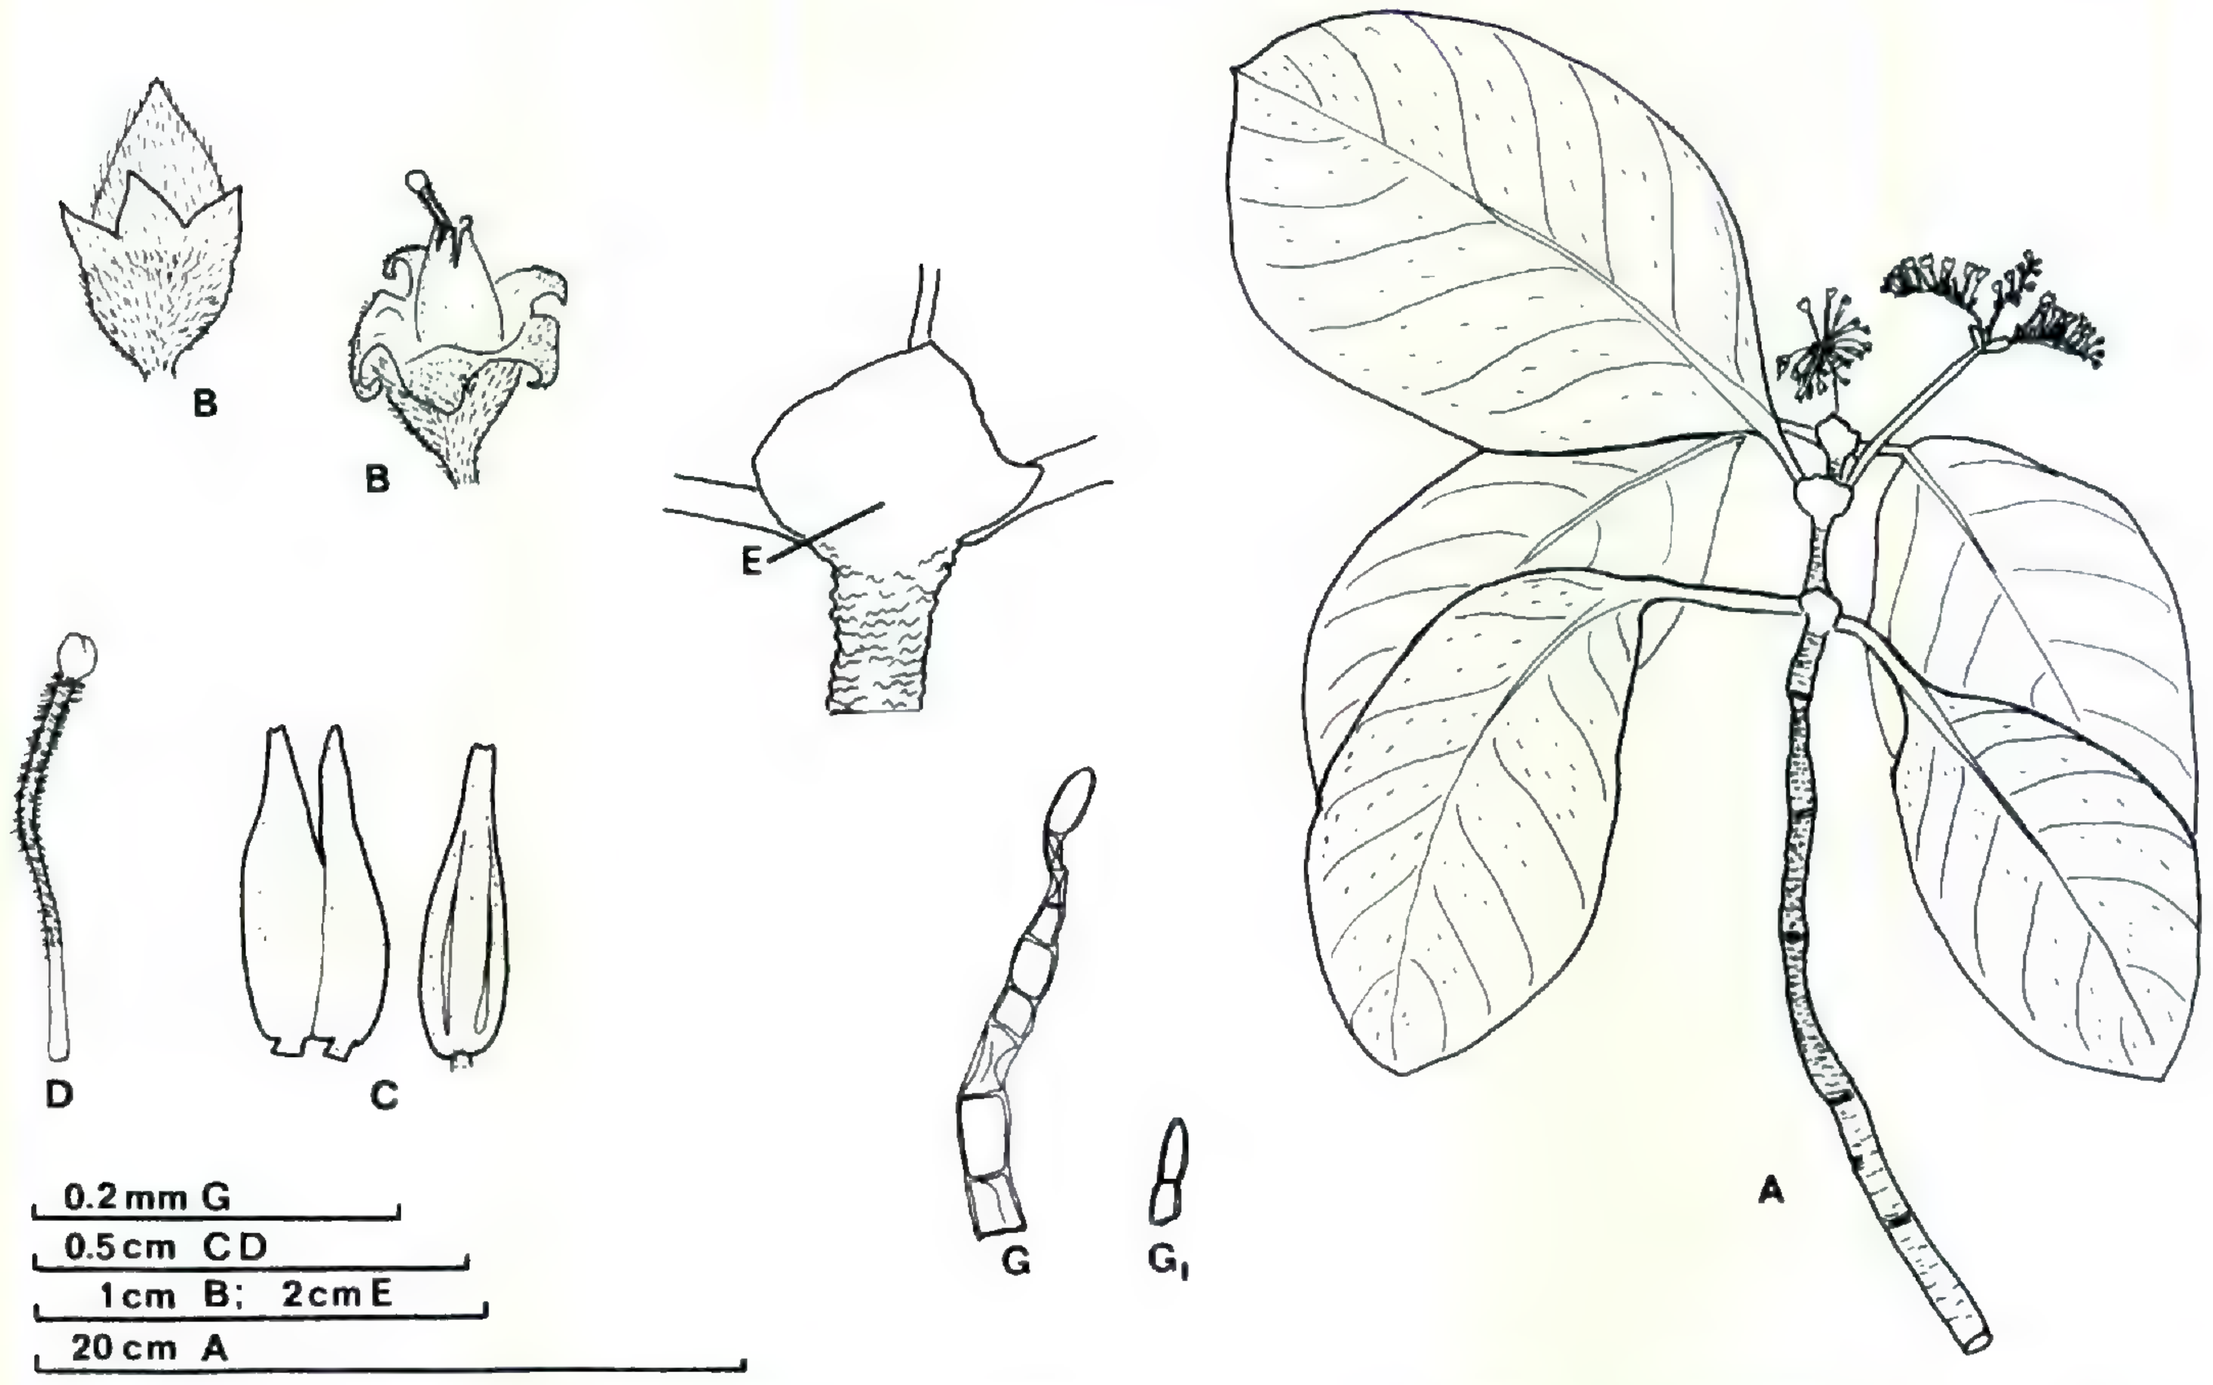

FIGURE 18. *Argostemma borragineum*.—A. Flowering branch.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—G. Hair from outer surface of the corolla.—G_1. Hair from inner surface of the corolla. From *Bremer 1668* (S).

almost glabrous (dry specimens) with very thick, veinless, elliptic, acuminate leaves and with very long internodes (*Burtt & Martin 5326, Nooteboom & Chai 1935*). Except for the very long internodes, they are similar to the type of *A. parvulum* from Baram. Another population includes the type of *A. murudense* with small, broad, ovate to rounded, obtuse to acute, densely pubescent leaves. These specimens are similar to the type of *A. moultonii* from the upper Baram. *Martin 38848* represents a different population with glabrous, obovate leaves with distinct prominent veins. From Ulu Tinjar in Baram, there is a collection (*Chai 34832*) with glabrous linear leaves. From Mt. Kinabalu, there are several different populations—one (*Gardner 88*) is glabrous with thick, veinless leaves but different from the glabrous specimens from Gunong Mulu. There are also specimens with ovate to obovate, slightly pubescent leaves. Plants from Kutei and Gunong Tapa Sia in Kalimantan (*Endert 3614, 4238* and *Axelius 112B*) are small rosettes with ovate, obtuse leaves having very long hairs. These collections are similar to *Nooteboom 921* from Gunong Alab in Sarawak. Perhaps these represent something different and distinct from *A. moultonii*, but based on the scanty material available, it is impossible to decide.

Additional specimens examined. BORNEO. BRUNEI: Kuala Belalong, 1959, *Ashton 199* (K). SABAH: W Coast Res., Kinabalu, Silau Silau trail, 1,400 m, 1979, *Anderson 4349* (MO, UC); Bebangan River, 5,000 ft., 1964, *Chew & Corner RSNB4618* (K); Tenompok, 5,000 ft., 1932, *Clemens 28250* (BM, BO, K); Tenompok, 5,500 ft., 1932, *Clemens 29499* (BM, K); Columbon basin, 4,500 ft., 1933, *Clemens 40049* (BM, BO, NY); Masilau, 6,000–8,000 ft., 1933, *Clemens 51670* (BM, NY); Marai Parai, 6,000 ft., 1958, *Collenette 60* (BM); 1937, *Grieswold 27* (GH); Lumu-Lumu, 1957, *Sinclair 9212* (E, L); W Coast Res., Gunong Alab, Crocker range, 1,600 m, 1980, *Argent 1308* (E); 1,400 m, 1969, *Nooteboom 921* (B, L); 1,600 m, 1969, *Nooteboom 1035* (L); Sandakan Res., Tawau Plateau, 50 m, 1977, *Gardner 88* (E, L); Interior Res., Sipitang, Ulu Moyah, 2,750 ft., *Wood SAN16695* (L, SING). 15. Argostemma borragineum Blume ex DC., Prod. 4: 417. 1830. TYPE: *Blume* in G-DC (holotype, G-DC, not seen; microfiche, LD!). Figure 18.

A. borragineum var. *rotundifolium* Valeton in H. Winkler, Bot. Jahrb. 44: 548. 1910. TYPE: S.O. Borneo: Batu Babi in Lumowia, 1908, *Winkler 2853* (lectotype, L; Bakh. f. in herb., confirmed here; isolectotypes, BM, BO).

A. streblosifolium Valeton, Icones Bogorienses 4: 271. 1914. TYPE: Borneo: Oeloe Tjihan, 1898–99, *Amdjah 319* (lectotype, BO; Bakh. f. in herb., confirmed here).

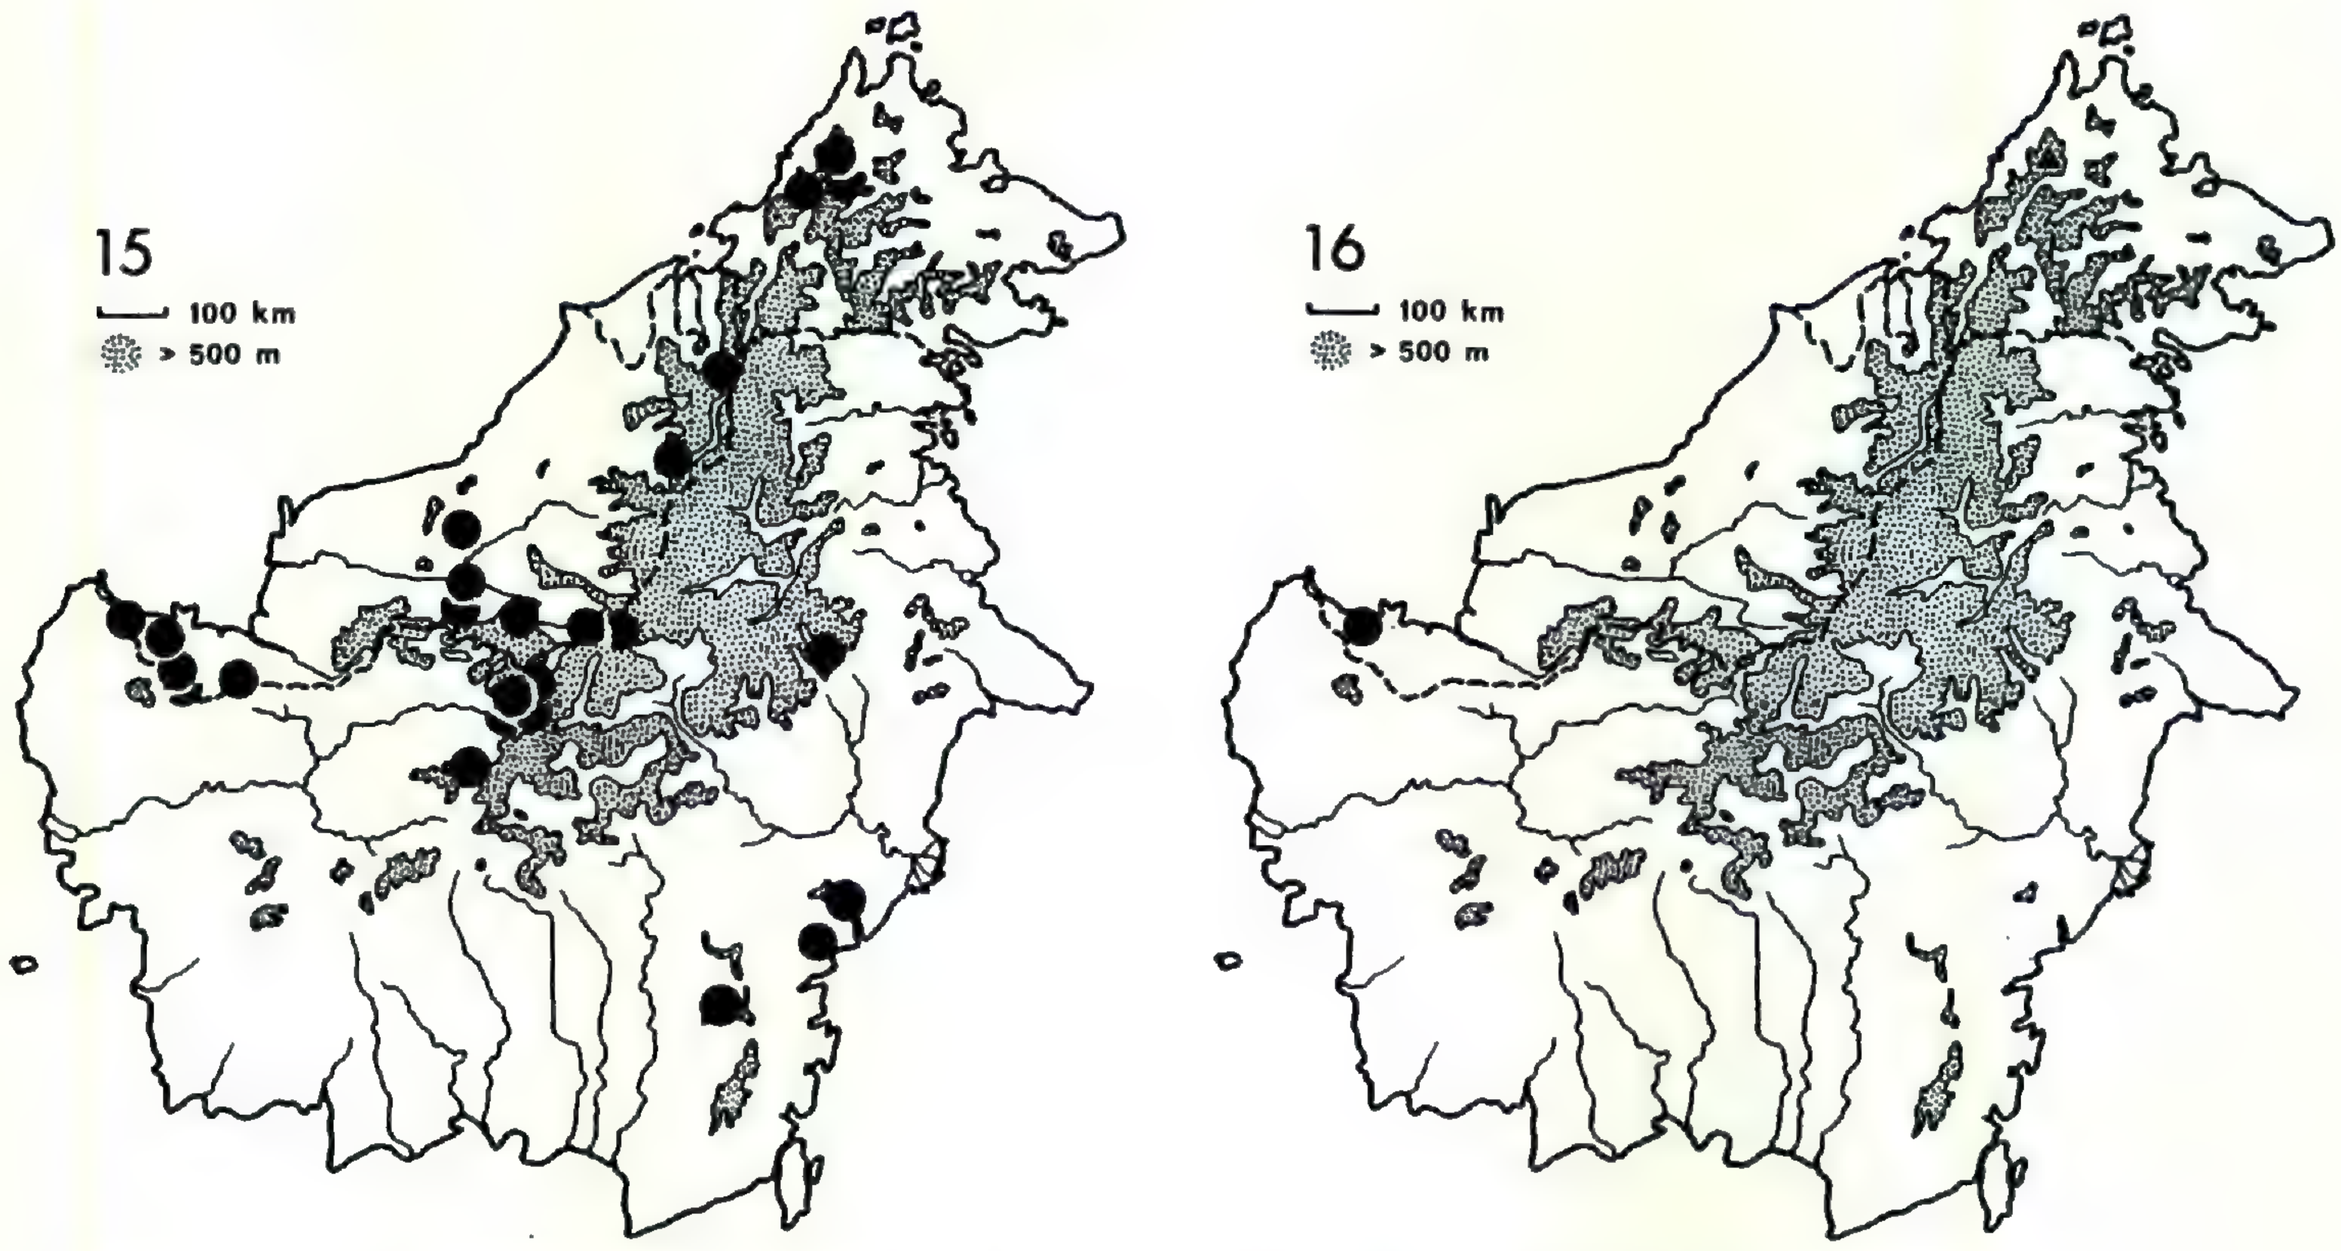
A. nutans var. *borneense* Ridley, J. Bot. 65: 33. 1927. TYPE: Borneo: Gunong Semapok ("Temapok" Ridley, 1927, sphalm.), 1,000 ft., 1920, *Moulton 6653* (holotype, K; isotype, SING).

Large, erect, isophyllous herb. Stem to 100 cm, glabrous to finely pubescent, black, with distinct scars in upper part; internodes 5–45 mm. Leaves opposite, equal; stipules persistent, ca. 10 mm long, broadly ovate, obtuse to acute at apex; petiole 0.5–7 cm, pubescent to glabrous; lamina 4.5–21 × 2.5–13 cm, broadly ovate to broadly obovate, basally rounded or acute to attenuate with the lobes equal, marginally entire or serrulate, apically obtuse, then sometimes with a point, or acute, herbaceous, glabrous to pubescent, most prominently pubescent on the veins below; midrib and primary veins (4–12 pairs) distinct. Inflorescences 25–160-flowered, umbelliform or with 2 or 3 scorpioid branches, solitary or a few together; peduncle 2–8 cm, glabrous to pubescent; bracts to 1 cm long, oblong to ovate; branches, if present, to 5 cm, glabrous to pubescent; pedicels to 2 cm, pubescent. Flowers 5-merous; calyx lobes 1–2 mm long, ovate to triangular or lanceolate, pubescent at least on basal parts; corolla 4–5 mm long, cleft to about middle, externally pubescent, internally glabrous to pubescent on the lobes; lobes ovate to triangular, recurved. Stamens 2–4 mm long, coherent, coriaceous; anther cells and apical appendages connate except for the most apical part; anther cone ovoid or shortly so, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ⅓ the anther length, thin and smooth; connective indistinctly passing over to the thecae, smooth. Style 5–6 mm long, pubescent, with a capitate stigma, long-exserted. Fruit without furrows or ribs but covered with emergences.

Winkler based *A. borragineum* var. *rotundifolium* on one collection with several specimens. All specimens are suitable for lectotypification. Bakhuizen f. (in herb.) selected the specimen in L and I follow his choice.

Valeton did not indicate any collection in the protologue of *A. streblosifolium*. In the Bogor herbarium (BO) there is only one specimen (*Amdjah 319*) that fits the picture and the protologue. Bakhuizen f. (in herb.) has selected that specimen, and I follow his choice.

Argostemma borragineum is one of the most common *Argostemma* species from low altitudes to ca. 2,000 m. It often grows near shady streams. All notes concerning its habitat place it on sandy, loamy soil, sandstone, or sedimentary rocks. It is highly variable. The majority of the plants are large, to 1 m high, with black and scarred stems. The opposite leaves are equal, large, and rounded, and the stipules are broad and distinctive. The inflorescences are densely pubescent and generally very large, sometimes with more than 150 flowers. They commonly develop two or three scorpioid branches, which become most prominent after anthesis. The corollas are cleft for about half their length into recurved lobes. The stamens are unique. The entire stamen is coriaceous and (on dry specimens) dark, and no differences can be discerned between the connective and the thecae, at least not from the dorsal side. The apical appendages



MAPS 15, 16. Distributions in Borneo.—15. *Argostemma borragineum.*—16. *A. flavescens.*

are separated in a characteristic way. The style is generally densely pubescent and bears a distinct capitate stigma strongly exserted. There are also plants uniformly smaller in all organs except for the flower, with smooth stems and more densely pubescent inflorescences, but there are also other small plants which have scarred stems. Several different populations have been collected from Mt. Kinabalu. I have not found any correlation between the morphological variation and any pattern of distribution.

Additional specimens examined. BORNEO. 16. Argostemma flavescens Bakh. f., Blumea 7: 331. 1953. TYPE: Borneo. Path to Matang, *Haviland 84/75* (holotype, SING). Figure 19.

Creeping, anisophyllous herb. Stem ca. 10 cm, branched, pubescent; internodes 4–8 mm. Leaves opposite, very unequal; stipules persistent, to 3 mm long, ovate to cordiform, acute at apex; larger leaves of the anisophyllous pairs with pubescent petioles 3–8 mm long; lamina 1–3 × 0.1–1.5 cm, obovate to ovate or elliptic, basally obtuse to acute and oblique, marginally entire to serrulate, apically acute, herbaceous, pubescent between the veins; midrib and primary veins (5–7 pairs) distinct. Nanophyllous leaves persistent, ca. 3 mm long, ovate. Inflorescences 1–3-flowered, solitary; peduncle 1–2 cm, pubescent; bracts to 0.3 cm, lanceolate; pedicels 0.5–0.8 cm, pubescent. Flowers 5-merous; calyx lobes ca. 1 mm long, broadly ovate, acute, pubescent in lower part; corolla 4 mm long. Stamens 5. Style pubescent, with an elliptic stigma, long-exserted.

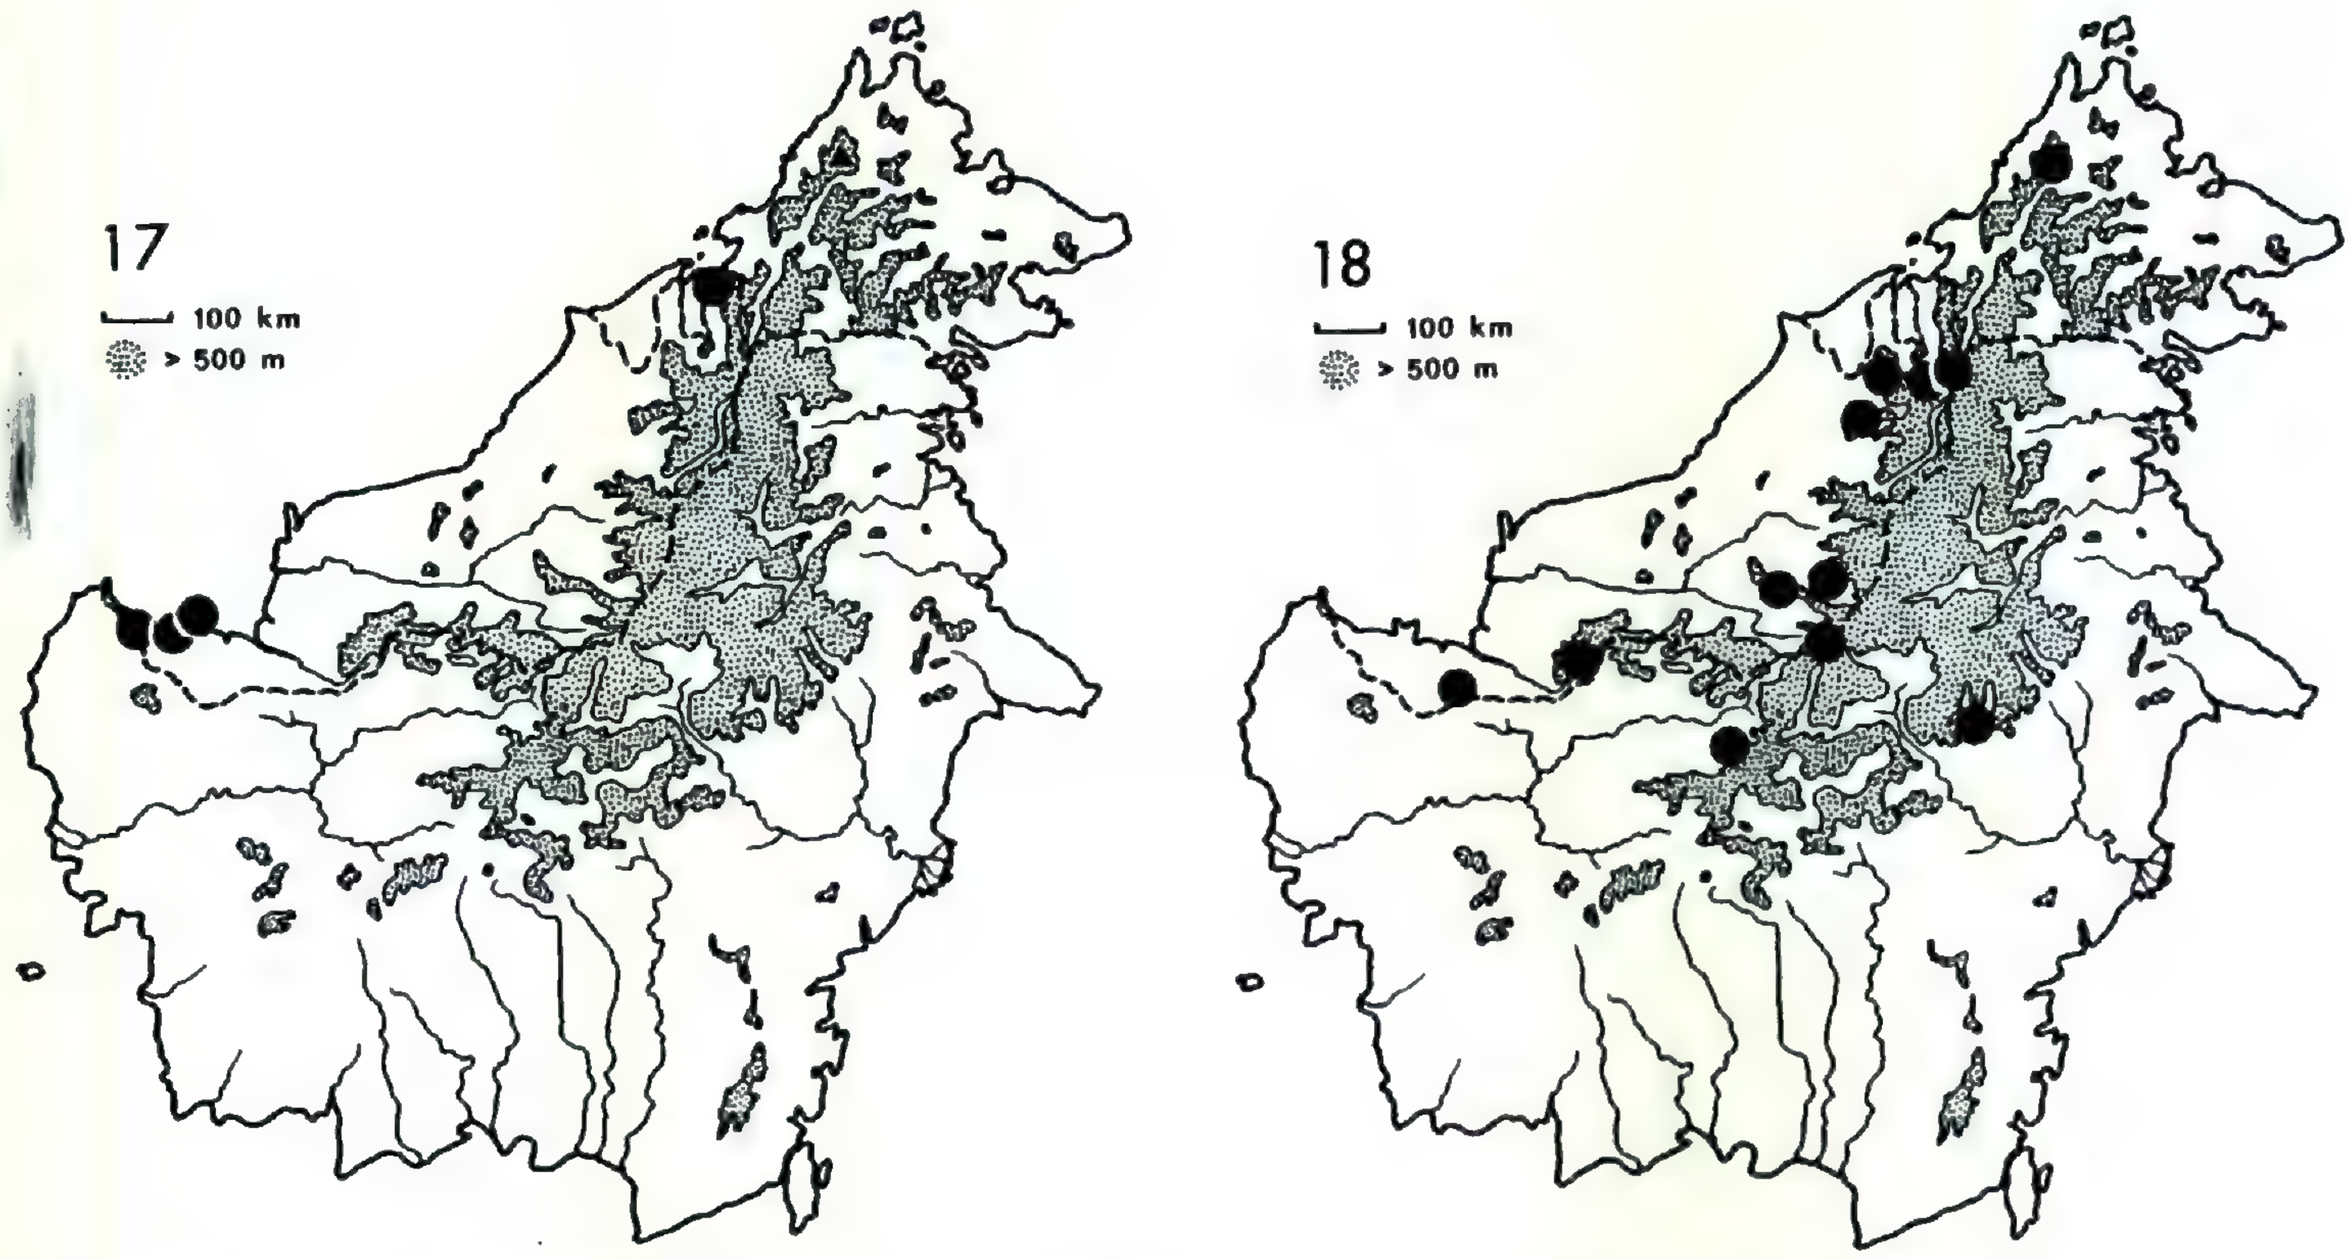
Argostemma flavescens is known from only two very poor collections. Both were examined, but there is still a great deal of information missing about the species. It has a characteristic habit, and its leaves are densely pubescent, particularly between the veins. In all other Borneo species the indumentum is more dense on the veins. The information on the flowers in the description is taken from Bakhuizen f. (1953, and pers. comm.). He placed *A. flavescens* close to *A. borragineum* because of its stamens. In my opinion it is not possible to determine its closest relatives within *Argostemma* at this time.

Additional specimen examined. BORNEO. SARAWAK: 1st Div., Mt. Matang, *Beccari 621* (L).

17. Argostemma chaii B. Bremer, nom. nov. *Argostemma enerve* Ridley (non Ridley 1912), nom. illeg., J. Bot. 65: 28. 1927. TYPE: Borneo. Sarawak: *native collector 1227* (holotype, K). Figure 20.

Small, erect, isophyllous herb. Stem very short to 11 cm, unbranched or slightly branched, glabrous; internodes very short to 10 mm long. Leaves opposite, subequal; stipules persistent, ca. 1 mm long, broadly ovate to cordiform, apically fringed with each point ending in a gland; petiole 3–9 mm long, glabrous; lamina 1.2–7 × 0.8–4.5 cm, ovate or elliptic or rarely lanceolate, basally acute to attenuate with the lobes equal, marginally entire, apically acute to obtuse, herbaceous to coriaceous, glabrous or with a few hairs above; midrib distinct, the primary veins obscure or absent. Inflorescences 2–15(–25)-flowered, umbelliform, solitary or a few together; peduncle 2–10 cm, glabrous; bracts to 0.6 cm long, ovate to lanceolate; pedicels 0.3–1.2 cm, pubescent or glabrous. Flowers 5-merous; calyx lobes 0.5–1 mm long, ovate to triangular, acute, glabrous to pubescent; corolla 3–5 mm long, cleft to near the base, externally pubescent or glabrous, internally glabrous; lobes lanceolate to oblong, erect-spreading. Stamens 3–4 mm long, at anthesis probably free; anther cells free, the apical appendage first connate then free, not forming a cone; filaments ca. ½ as long as the anthers, equal, straight; sacs opening completely longitudinally; apical appendages very short, thick and smooth; connective distinct, smooth. Style ca. 3–6 mm long, glabrous, with a discoid stigma, long-exserted. Fruit without furrows or ribs.

This species is named after Mr. Paul Chai of the Forest Department, Sarawak. *Argostemma chaii* grows on dead wood, wet rocks, or wet ground in the lowland rainforest, to 300 m. This species is a very small herb, with leaves more or less condensed into rosettes. Its primary veins are obscure, and the stipules are broad and fringed apically with colleters. The flowers are characteristic, with thick corolla lobes and free anthers. The filaments are wide, fixed at the base of the corolla, and adnate with it for a short distance. The stigma is discoid.



MAPS 17, 18. Distributions in Borneo.—17. *Argostemma chaii.*—18. *A. gracile.*

Argostemma chaii is a rare species collected from two different areas in Sarawak. The collections from the 5th Division are hairy on the pedicels, calyx, and on the outside of the corolla. The leaves also have scattered hairs. From the 1st Division the plants (including the type specimen) are glabrous in all parts. From Mt. Matang in the 1st Division the leaves are distinctly larger than from other localities.

Bakhuizen f. (pers. comm.) has treated this taxon as a synonym of *A. inaequale* (Bennett, 1838). Their habits are similar, but their flowers are different. *Argostemma inaequale* does not have the thick corollas nor the discoid stigma, and its anthers have long apical appendages, while the anther appendages of *A. chaii* are very short.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Bako, Telok Asam, 100 ft., 1956, *Purseglove 5096* (SING); 1st Div., Mt. Matang, 800 ft., 1954, *Brooke 9474* (L), *9478* (BM, L); 1st Div., Krangi, 1954, *Brooke 8502, 8512* (BM, L); 4th Div., G. Mulu, 120 m, 1978, *Nielsen 368* (AAU); 5th Div., Lawas, 1955, *Brooke 10542, 10268* (BM, L).

18. Argostemma gracile Stapf, Trans. Linn. Soc. London Bot. 4: 168. 1894. *Argostemella gracilis* (Stapf) Ridley, J. Bot. 65: 41. 1927. TYPE: Borneo. Kinabalu, Penokok, 3,500 ft., *Haviland 1325* (holotype, K; isotypes, SAR, SING). Figure 21.

A. podochiloides Merrill, Mitt. Inst. Allg. Bot. Hamburg 7: 279. 1937. Type: West Borneo: Bukit Tilung, 750 m, 1925, *Winkler 1479* (holotype, HBG; isotype, NY).

Small, creeping, anisophyllous herb. Stem 5–20 cm, slightly branched or unbranched, glabrous;

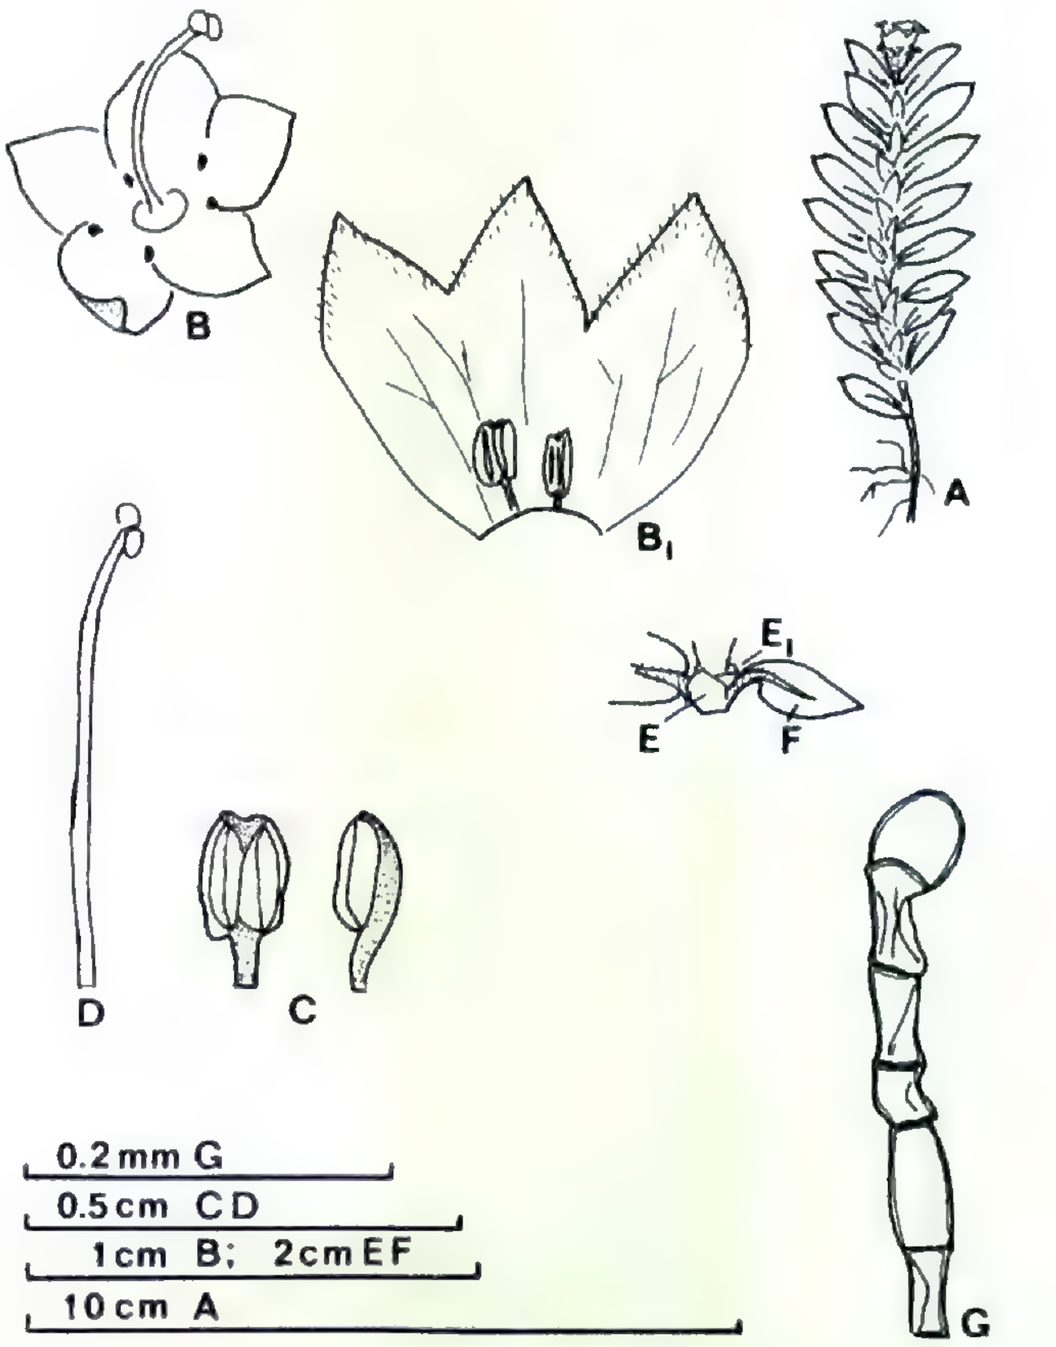


FIGURE 21. *Argostemma gracile.*—A. Habit.—B. Flower, inner surface of calyx.—B_1. Inside view of part of a corolla.—C. Anthers.—D. Style.—E. Stipule.—E_1. Amplexicaul sheath.—F. Nanophyllous leaf.—G. Hair from outer surface of the corolla. A from *Bremer 1667* (S); B–G from *Argent & Coppins 1142* (E).

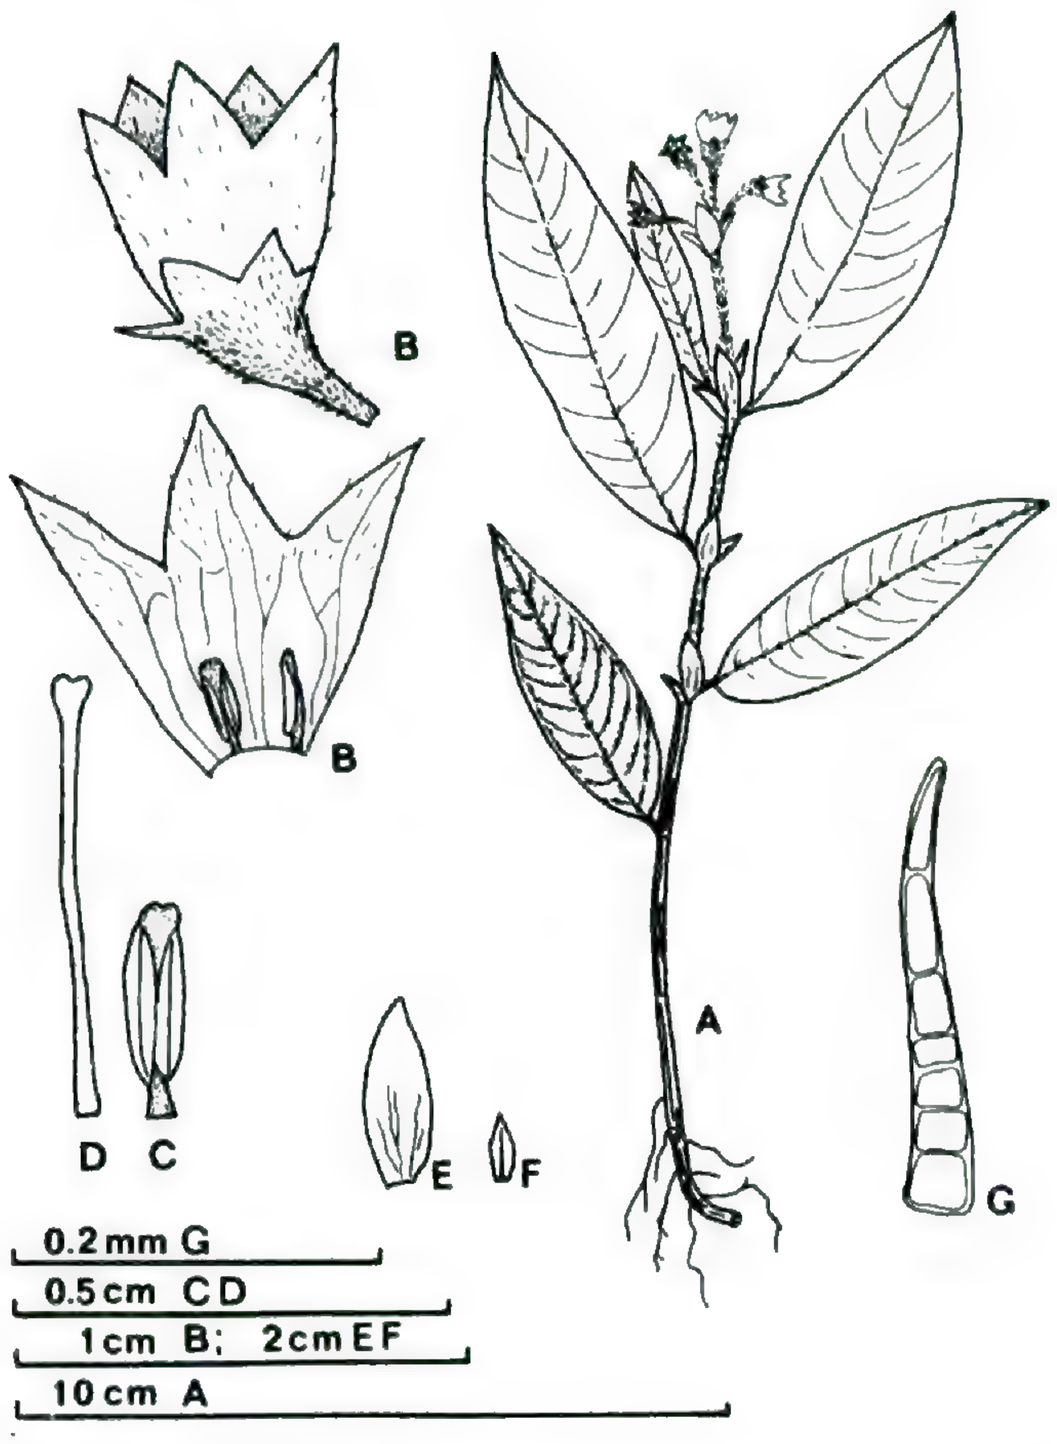

FIGURE 22. *Argostemma brachyantherum*. —A. Habit.—B. Flower.—C. Anther.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—G. Hair from outer surface of the corolla. A from *Bogle et al. 389* (GH); B–G from *Hou 225* (L).

internodes 2–5 mm. Leaves opposite, very unequal, distichous, pale silvery underneath; stipules persistent, ca. 2 mm long, broadly ovate or cordiform to auriculiform, ending apically in a distinct point; stipules and petioles ± fused into an amplexicaul sheath. Larger leaves of the anisophyllous pairs with pubescent petioles 0.5–1.5 mm long; lamina 0.6–1.7 × 0.3–0.7 cm, oblong to narrowly oblong or rarely obovate, basally rounded or acute with the lobes equal or oblique, marginally entire, apically obtuse or obtuse with a point, or acute, herbaceous to coriaceous, glabrous or with scattered hairs somewhat concentrated along the midrib on both sides; midrib distinct but without primary veins. Nanophyllous leaves persistent, 4–5 mm long, ovate. Inflorescences 1-flowered, solitary, without peduncle; pedicel 0.2 cm, pubescent. Flowers 5(or 6)-merous; calyx lobes 2–3 mm long, triangular to cordiform, pubescent in lower parts; corolla ca. 8 mm long, cleft less than ⅓ its length, externally glabrous and internally pubescent only along the margins of the lobes; lobes broadly triangular, spreading. Stamens ca. 2.5 mm long, free; anther cells and apical appendage free, not forming a cone; filaments ca. ⅓–½ as long as the anthers, equal, straight; sacs opening completely longitudinally; apical appendages almost absent, thick and slightly papillose; connective distinct, smooth. Style ca. 5 mm long, glabrous, with a discoid, bifid stigma, long-exserted. Fruit without furrows or ribs.

Argostemma gracile grows on fallen rotten logs or on rocks among mosses in submontane or montane forests from 1,000 to 1,600 m. One collection (*Bremer 1667*) is from low elevation, 350 m, in an area of lowland rainforest with big boulders covered by mosses.

Argostemma gracile is easily recognized, with its creeping habit and distichous, anisophyllous leaves, the nanophyllous leaves above the larger leaves. The leaves are thick with a distinct midrib but without other visible veins. They are silvery white beneath. The petiole and midrib have a few hairs on both surfaces, but one exception is the type specimen of *A. podochiloides* with completely glabrous leaves. The stipules and petioles are more or less connate with the amplexicaul sheath. This character, combined with the glabrous leaves, has been used for recogniton of *A. podochiloides*, a species not accepted here. Flowers in *A. gracile* are solitary on very short pedicels and without peduncles. The corolla is campanulate with spreading lobes. The stamens are free, and there are practically no apical appendages. The stigma is distinctly bifid and discoid.

Additional specimens examined. BORNEO. abalu, 3,000 ft., *Haviland 1326* (holotype, K). Figure 22.

A. kinabaluense Wernham in Gibbs, J. Linn. Soc. Bot. 42: 88. 1914. TYPE: British North Borneo. Kinabalu, near Dahobang and Kinitaki rivers, 4,000–5,000 ft., 1910?, *Gibbs 4056* (holotype, BM; isotype, K).

Erect, anisophyllous herb. Stem 3–40(–80) cm, slightly branched or unbranched, densely pubescent in upper part, in lower part with corky or papery bark; internodes 2–20(–45) mm. Leaves opposite, very unequal; stipules deciduous or persistent, 4–10 mm long, oblong to lanceolate, acute to acuminate at apex; larger leaves of the anisophyllous pairs with pubescent petioles 2–5 mm long; lamina 2.5–9 × 1–3 cm, obovate or oblanceolate or elliptic to narrowly elliptic, basally acute to obtuse with the lobes equal or oblique, marginally entire or serrulate, apically acute to acuminate, herbaceous, glabrous or with scattered hairs above, pubescent on the veins below; midrib and primary veins (6–14 pairs) distinct. Nanophyllous leaves deciduous or persistent, 3–10 mm long, ovate to lanceolate, acute to acuminate. Inflorescences 1–6(–12)-flowered, umbelliform, solitary or a few together; peduncle 1–3 cm, pubescent; bracts 0.2–0.7 cm long, ovate to lanceolate; pedicels 0.5–1.5 cm long, pubescent. Flowers 5-merous; calyx lobes 2–5 mm long, ovate to triangular, acute, sparsely pubescent; corolla campanulate, cleft less than ⅓ their length, externally pubescent, internally papillose to pubescent only on the lobes; lobes triangular, acute, erect(?). Stamens 2–3(–4) mm long, free; anther cells and apical appendages free, not forming a cone; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅕ the anther length, thick and slightly papillose; connective distinct, smooth. Style 3–6 mm long, glabrous, with a capitate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma brachyantherum grows in submontane or montane forest between 1,000 and 2,100 m in northeastern Borneo.

This species is generally small to medium sized with anisophyllous leaves and a few large, campanulate flowers with free, very short anthers. The indumentum, particularly on the leaves, differs among the collections, otherwise the species is rather uniform. The specimen *Argent & Coppins 1081* is much larger than those of other collections and also has many more flowers. Some characters of this specimen deviate from the typical range for the species and are enclosed in parentheses in the description.

Additional specimens examined. BORNEO. SABAH: W Coast Res., Kinabalu, vicinity of Kambaranga, 7,040 ft., 1962, *Bogle et al. 389* (GH); Tenompok, 5,000 ft., 1932, *Clemens 28179* (BM, BO, G, K, L, NY); Marai Parai, 5,000 ft., 1933, *Clemens 35136* (BM, BO, L, NY, UC); Marai Parai spur, 1915, *Clemens 10981* (UC); Upper Kinabalu, 6,000 ft., 1933, *Clemens 51020* (BM, G, K, NY); Marai Parai, 5,000 ft., 1958, *Collenette A77* (BM); on ridge parallel to Kinataki River, 45 ft., *Collenette A103* (BM); 1,650 m, 1966, *Ding Hou 225* (K, L); Kamarangoh, 7,000 ft., 1967, *Price 194* (K); W Coast Res., Gunong Alab, 1,400 m, 1969, *Nooteboom*

20. Argostemma brookei B. Bremer, sp. nov. TYPE: Borneo. Sarawak: 1st Div., Berumput, 4,800 ft., 1954, *Brooke 8562* (holotype, L; isotypes, BM, G, UC). Figure 23.

Herba inflorescentiis valde pubescentibus, staminibus liberis. Folia opposita, illis parium inaequalissimis. Inflorescentia umbelliformis, floribus pusillis. Lobi calycis ovati ad triangulares, acuti, patentes. Corolla profunde fissa. Lobi corollae recurvi. Stamina libera, sed approximata. Appendix apicalis ¼ longitudinem antherae aequans, crassa, laevis. Connectivum distinctum. Stylus glaber, stigmate leviter capitato.

Argostemma havilandii, A. calcicolum, A. trichosanthes, A. humifusum, A. psychotrioides, A. variegatum simile sed lobis corollae profunde fissis, staminibus liberis differt.

Erect, anisophyllous herb. Stem 5–22 cm, slightly branched or unbranched, finely pubescent; internodes 3–15 mm. Leaves opposite, generally very unequal; stipules deciduous or persistent, 4–6 mm long, ovate, acuminate at apex; larger leaves of the anisophyllous pairs with pubescent petioles 2–35 mm long; lamina 3–70 × 0.8–2.2 cm, oblanceolate to narrowly elliptic, basally acute with the lobes equal, marginally entire, apically acuminate, rarely acute or obtuse, herbaceous, glabrous above, pubescent on the veins below; midrib and primary veins (6–10 pairs) distinct. Nanophyllous leaves deciduous or persistent, 4–10 mm long, ovate to lanceolate, acute to acuminate. Inflorescences 5–16-flowered, umbelliform, solitary or a few together; peduncle 0.8–1.7 cm, pubescent; bracts ca. 0.5 cm long, lanceolate; pedicels 0.6–1.0 cm, pubescent. Flowers 5-merous; calyx lobes ca. 2 mm long, ovate to triangular, acute, sparsely pubescent, spreading; corolla cleft to near the base, externally with a few hairs, internally pubescent only on the distal part of the lobes; lobes ovate to triangular, recurved. Stamens ca. 3 mm long, free but close together; anther cells and apical appendage free; no true cone; filaments short, equal, straight; sacs opening completely longitudinally; apical appendage ca. ¼ the anther length, thick and smooth; connective distinct, smooth. Style ca. 6 mm long, glabrous, with a slightly capitate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma brookei has been collected from the ground in the forest in the Poi (= Pueh) range at elevations of 1,000 to 2,000 m.

It is medium sized with oblanceolate, anisophyllous leaves. The upper part of the stems, the peduncles, and the whole inflorescences are covered by rather stiff hairs. The length of the calyx lobes is intermediate between the short ones, most common among the Borneo species, and the long lobes of *A. psychotrioides*.

Most specimens of this taxon have been determined as *A. brachyantherum*, another mountain species, which occurs mainly at Kinabalu. In habit they are similar, but *Argostemma brookei* has many small flowers with deeply cleft corollas having evidently recurved lobes. The free anthers are longer and stand close together, like a cone; the apical appendages are much longer, and the filaments are shorter than in *A. brachyantherum*.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Mt. Poi (= Pueh), summit ridge, northern end, 4,400 ft., 1956, *Bell 2068* (BM); 6,000 ft., 1929, *Clemens 20064* (K, NY); forested slopes, 1929, *Clemens 20331* (NY); 4,500–5,500 ft., 1924, *Mjöberg s.n.* (UC); 1st Div., Gunong Berumput, 3,000 ft., 1954, *Brooke 8599* (L); 4,870 ft., 1962, *Burtt & Woods 2800* (E).

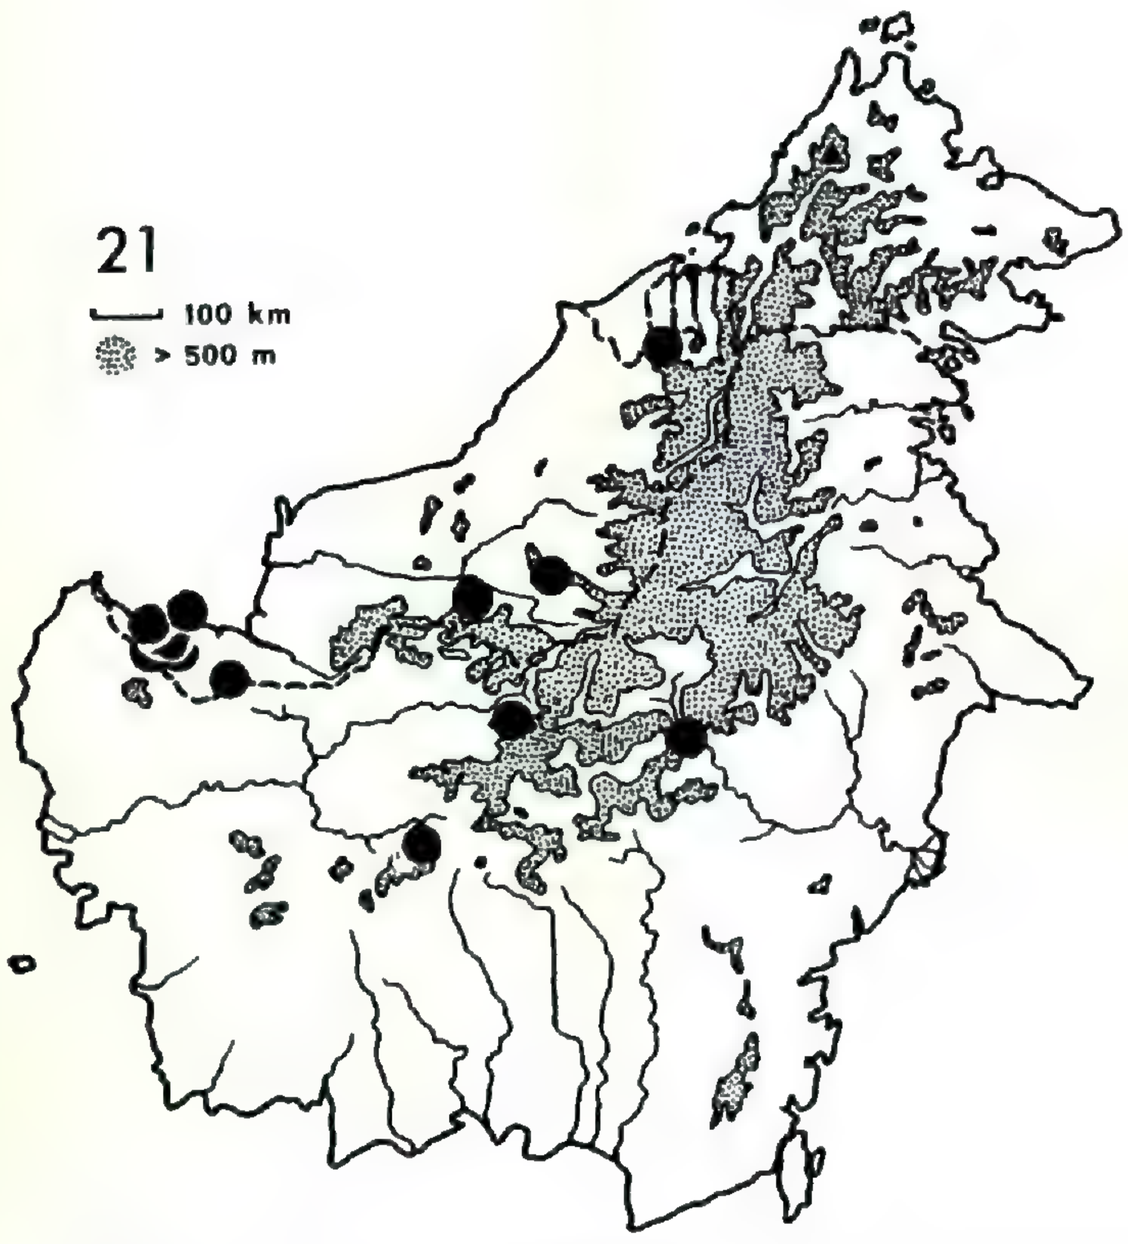
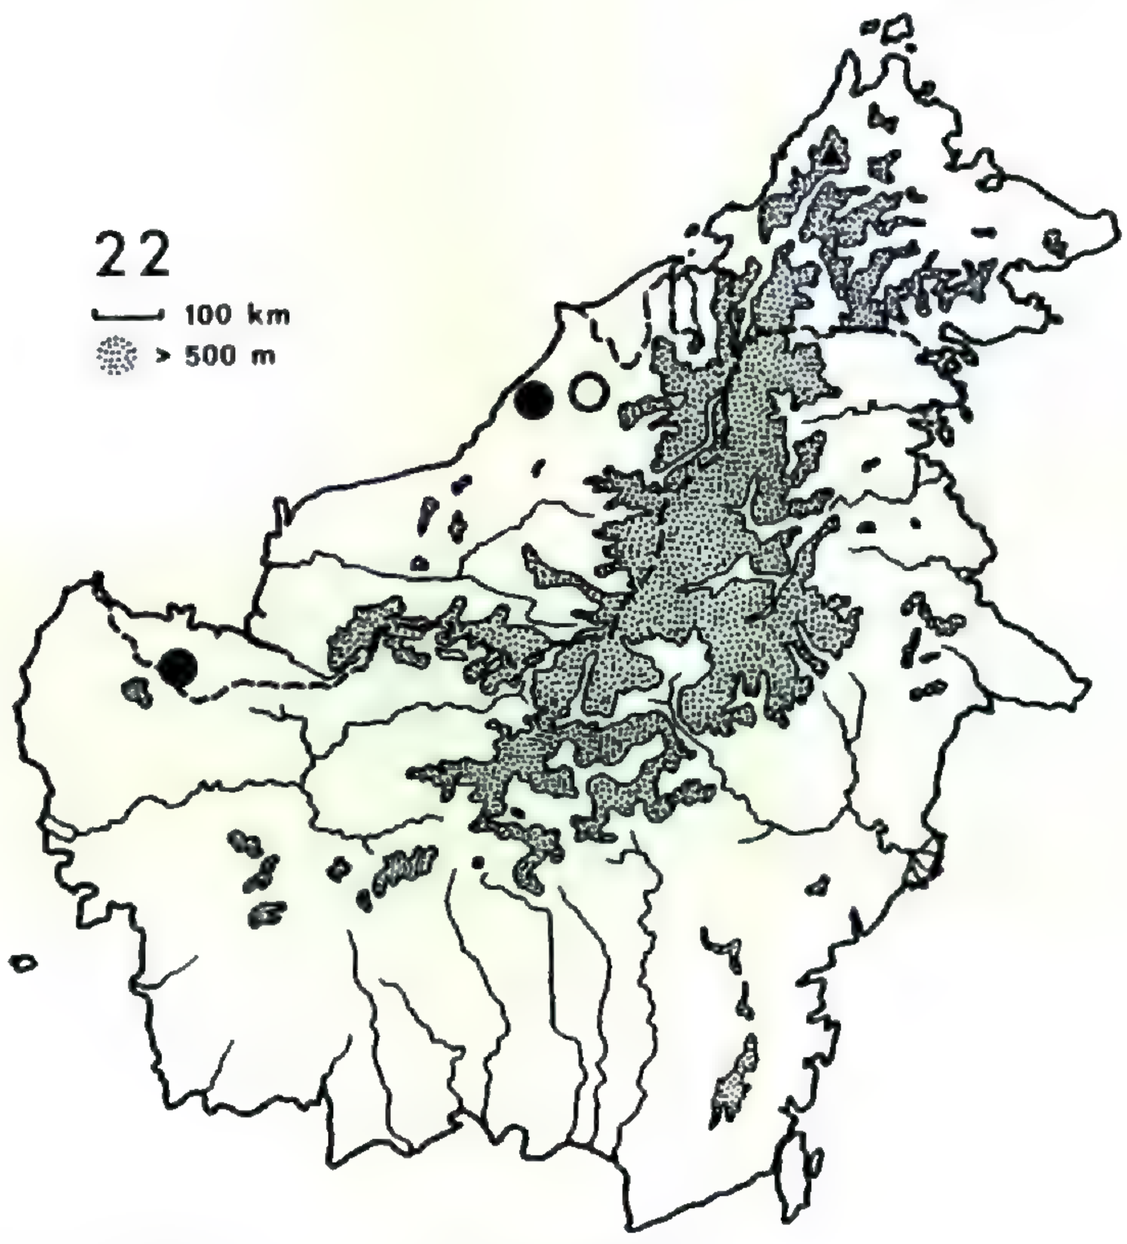
A. hallieri var. *sparsipilum* Merr., Mitt. Inst. Allg. Bot. Hamburg 7: 279. 1937. TYPE: West Borneo: Sungei Bika, 50 m, 1925, *Winkler 1428* (holotype, HBG; isotypes, HBG, NY).

Erect, anisophyllous herb. Stem 10–60 cm, unbranched or slightly branched, glabrous or rarely slightly pubescent, lower and older parts pale brown with elevated corky to papery longitudinal ridges and/or with transverse bars; internodes 9–30 mm. Leaves opposite, very unequal; stipules deciduous, 4–7 mm long, ovate to broadly ovate, obtuse at apex. Larger leaves of the anisophyllous pairs with glabrous or finely pubescent petioles 4–8 mm long; lamina 4–13 × 1.2–5 cm, obovate or oblanceolate to ovate to lanceolate, basally cuneate to acute or attenuate with the lobes equal, marginally entire, apically acuminate or rarely acute to obtuse, herbaceous to coriaceous, glabrous above or with a few hairs on the veins and margins, glabrous or generally pubescent on the veins below; midrib distinct, primary veins (6–11 pairs) generally distinct. Nanophyllous leaves deciduous, 4–10 mm long, lanceolate to linear. Inflorescences 4–18-flowered, umbelliform, solitary or a few together; peduncle 1.7–4.5 cm, glabrous; bracts to 0.6 cm long, ovate to broadly ovate; pedicels 0.7–1.8 cm,





MAPS 21, 22. Distributions in Borneo.—21. *Argostemma havilandii*.—22. *A. calcicolum*.

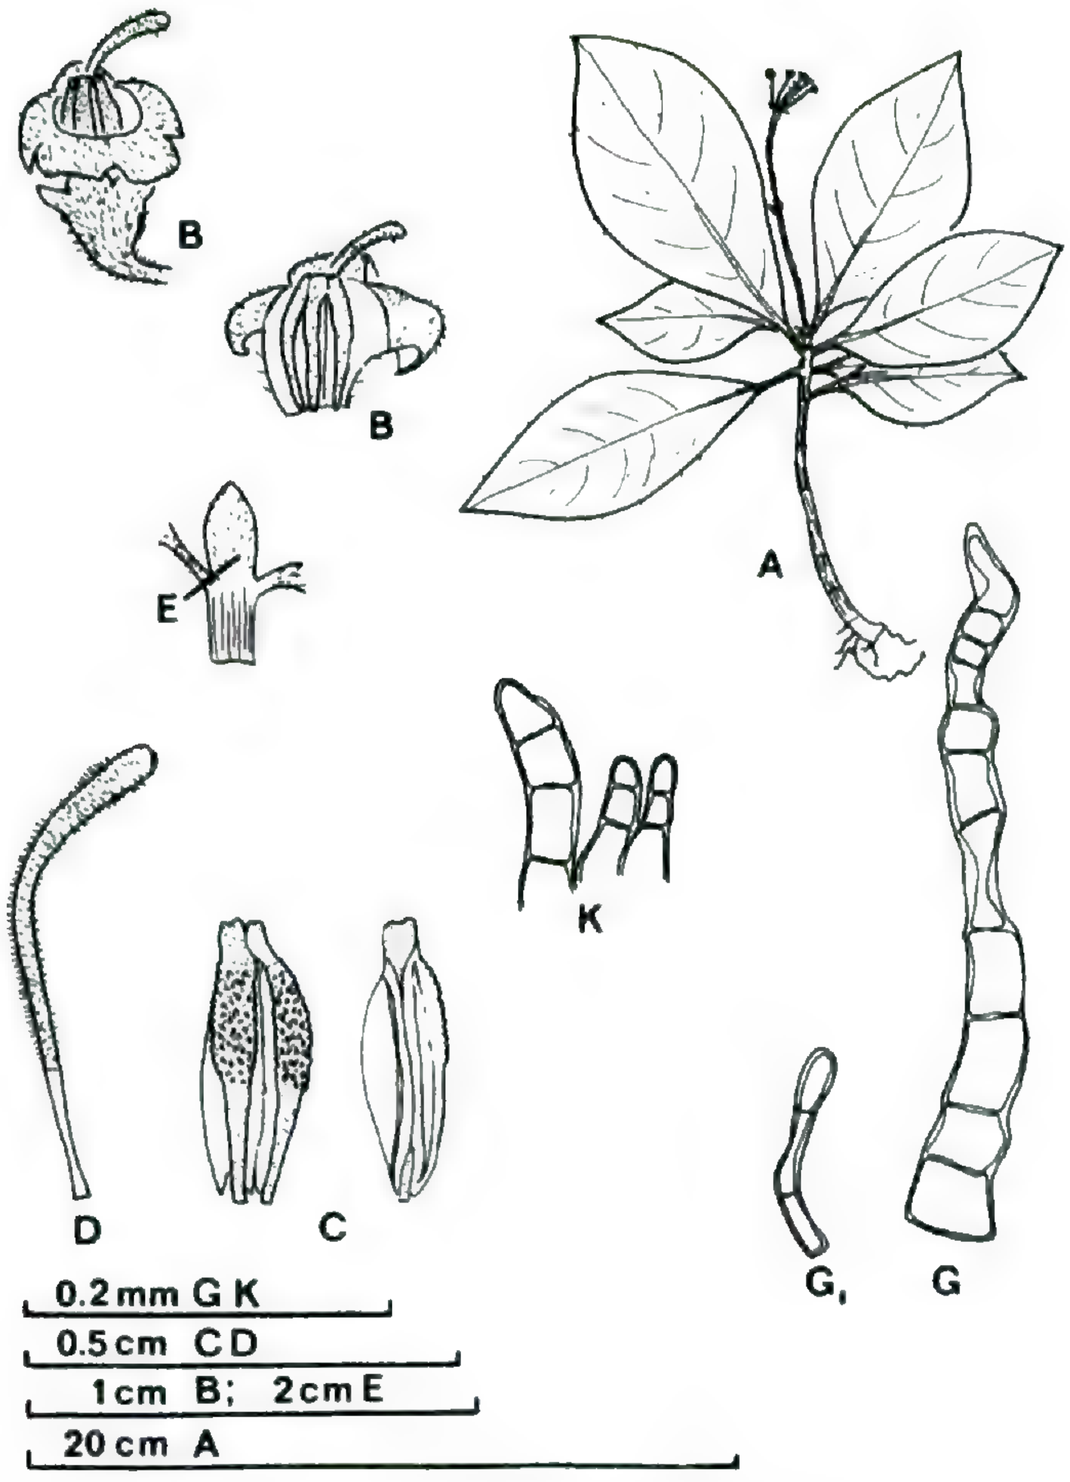


FIGURE 25. *Argostemma calcicolum.*—A. Habit.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—G. Hair from outer surface of the corolla.—G_1. Hair from inner surface of the corolla.—K. Hairs from the connectives. A, E from *Burtt & Woods 2005* (E); B–D, G, I from *Bremer 1707* (S).

pubescent or rarely glabrous. Flowers 5-merous; calyx lobes ca. 1 mm long, ovate to orbicular, obtuse or acute, pubescent; corolla 3–4 mm long, cleft to about ½, externally pubescent, internally papillose to pubescent only on the lobes; lobes ovate to triangular, recurved. Stamens 3–4 mm long, coherent; anther cells free, the apical appendages connate; anther cone ovoid to shortly so, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅛ the anther length, thick, coriaceous, smooth; connective coriaceous, distinct, generally smooth. Style ca. 3–6 mm long, pubescent, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

Valeton based *A. lanceolatum* on four collections by *Teysmann* and *Hallier*, in BO and L. All are suitable for lectotypification. Bakhuizen f. (in herb.) has selected *Teysmann 11292* in L, and I follow his choice.

Bakhuizen f. selected the K specimen of *A. havilandii* as the type (= holotype). This is a mistake because Ridley (1912) stated that the plants are preserved in the Singapore Botanical Gardens (note under *A. ophirense*).

Argostemma havilandii has a scattered distribution. Most, if not all, collections are from limestone. It grows from 50 to 1,100 m elevation on litter or more or less as an epiphyte on tree trunks, usually in lowland rainforest.

It is easily distinguished. The stem is black on the upper part (on dry specimens), and the lower part is pale brown to gray and papery to corky with elevated ridges and with more or less distinct transverse bars. The corolla is cleft to about its middle into recurved lobes. The anther cone is low and pale yellow to creamish. The connectives are distinct, and the thecae are separated from each other at anthesis. The broad, thick apical appendages are connate along their whole length.

Argostemma havilandii is easily circumscribed. There is little variation among the populations except for width and hair cover of the leaves. From around Gunong Api there is a population with a very dense hair cover, even more distinctive than the densely pubescent specimens from Sungei Bika in Kalimantan, where they have been described as *A. hallieri* var. *sparsipilum*.

Additional specimens examined. BORNEO. SARAWAK: 1st Div., Mt. Matang: 500 ft., 1954, *Brooke 9487* (L); 1,400 ft., 1927–1928, *native collector 5181* (NY, UC); 1st Div., Bau, Seburan, 200 ft., 1960, *Anderson 8982* (K, L, SAR); Seburan, 300 ft., 1960, *Anderson 12915* (K, L, SAR); Seburan, 200 ft., 1960, *Anderson 14600* (K, L, SAR); Jambusan, 100 ft., 1960, *Anderson 12581* (K, L, SAR); Bidi Gunong Umbut, 1979, *Bremer 1717* (S, SAR); 1st Div., Sabal, 1979, *Bremer 1662* (S, SAR); 1st Div., Setapok, mi. 4½ Batu Kawa Road, 1975, *James Mamit S35046* (L); 1st Div., Bako, 1979, *Bremer 1689* (S, SAR); 1st Div., Kuching, 1955, *Brooke 9770, 10792* (BM, L); 1893, *Haviland s.n.* (BM, L); 1913, *native collector s.n.* (E); 1st Div., Semengoh, 300 ft., 1958, *Anderson 9106* (L, SAR); 1979, *Bremer 1647* (S, SAR); 4th Div., Gunong Mulu, 1975, *Burtt 8300* (E); 4th Div., Gunong Api, 2,900 ft., 1971, *Anderson S30826* (E, K, L); 1,000 ft., 1977, *Argent et al. 666* (E); 3,500 ft., 1970, *Chai S30085* (K, L, SAR); 7th Div., Bukit Salong, 1980, *Burtt 12734* (E); without loc., *native collector 1232* (A); 1914, *native collector 2403* (A). 22. Argostemma calcicolum B. Bremer, sp. nov. TYPE: Borneo. Sarawak: 1st Div., Bukit Manok, halfway between Teng Bukap and Padawan, low alt., 1979, *Bremer 1707* (holotype, S; isotypes, K, L, SAR). Figure 25.

Herba caulibus porcatis et suberosis ad papyraceis. Folia opposita, illis parium aequalibus. Inflorescentiae umbelliformes aut ramis duobus scorpioides. Lobi calycis triangulares ad ovati, acuti. Corolla ad dimidio fissa. Lobi corollae recurvi. Antherae liberae. Appendices apicales connatae, ¼–⅕ longitudinem antherarum aequans, cras-

sae, coriaceae, laeves. Connectivum distinctum, papillosum. Stylus pubescens, stigmate clavato.

Argostemma havilandii simile, sed planta plus pubescens, foliis oppositis aequalibus differt.

Erect, isophyllous herb. Stem 5–30 cm, slightly branched or unbranched, slightly pubescent, the lower and older parts pale brown with elevated corky to papery longitudinal ridges and/or with transverse bars; internodes 4–10 mm. Leaves opposite, equal or subequal; stipules deciduous, 5–10 mm long, ovate to oblong, acute to obtuse at apex; petiole 3–14 mm long, pubescent; lamina 5–17 × 2–7 cm, obovate to elliptic, basally cuneate to attenuate with the lobes equal, marginally entire or serrulate, apically acuminate, herbaceous, pubescent on both surfaces; midrib and primary veins (7–9 pairs) distinct. Inflorescences 3–30-flowered, umbelliform or with 2 scorpioid branches, solitary or a few together; peduncle 3–4.5 cm, pubescent, the bracts to 0.5 cm long, lanceolate; pedicels 0.5–0.7 cm, pubescent. Flowers 5-merous; calyx lobes ca. 1 mm long, triangular to ovate, acute, pubescent; corolla ca. 4 mm long, cleft to about ½, externally pubescent, internally papillose to pubescent only on the lobes; lobes ovate to triangular, recurved. Stamens ca. 3.5 mm long, coherent; anther cells free, the apical appendages connate; anther cone ovoid to shortly so, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅕ the anther length, thick, coriaceous, smooth; connective coriaceous, distinct, papillose. Style 5–6 mm long, pubescent, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

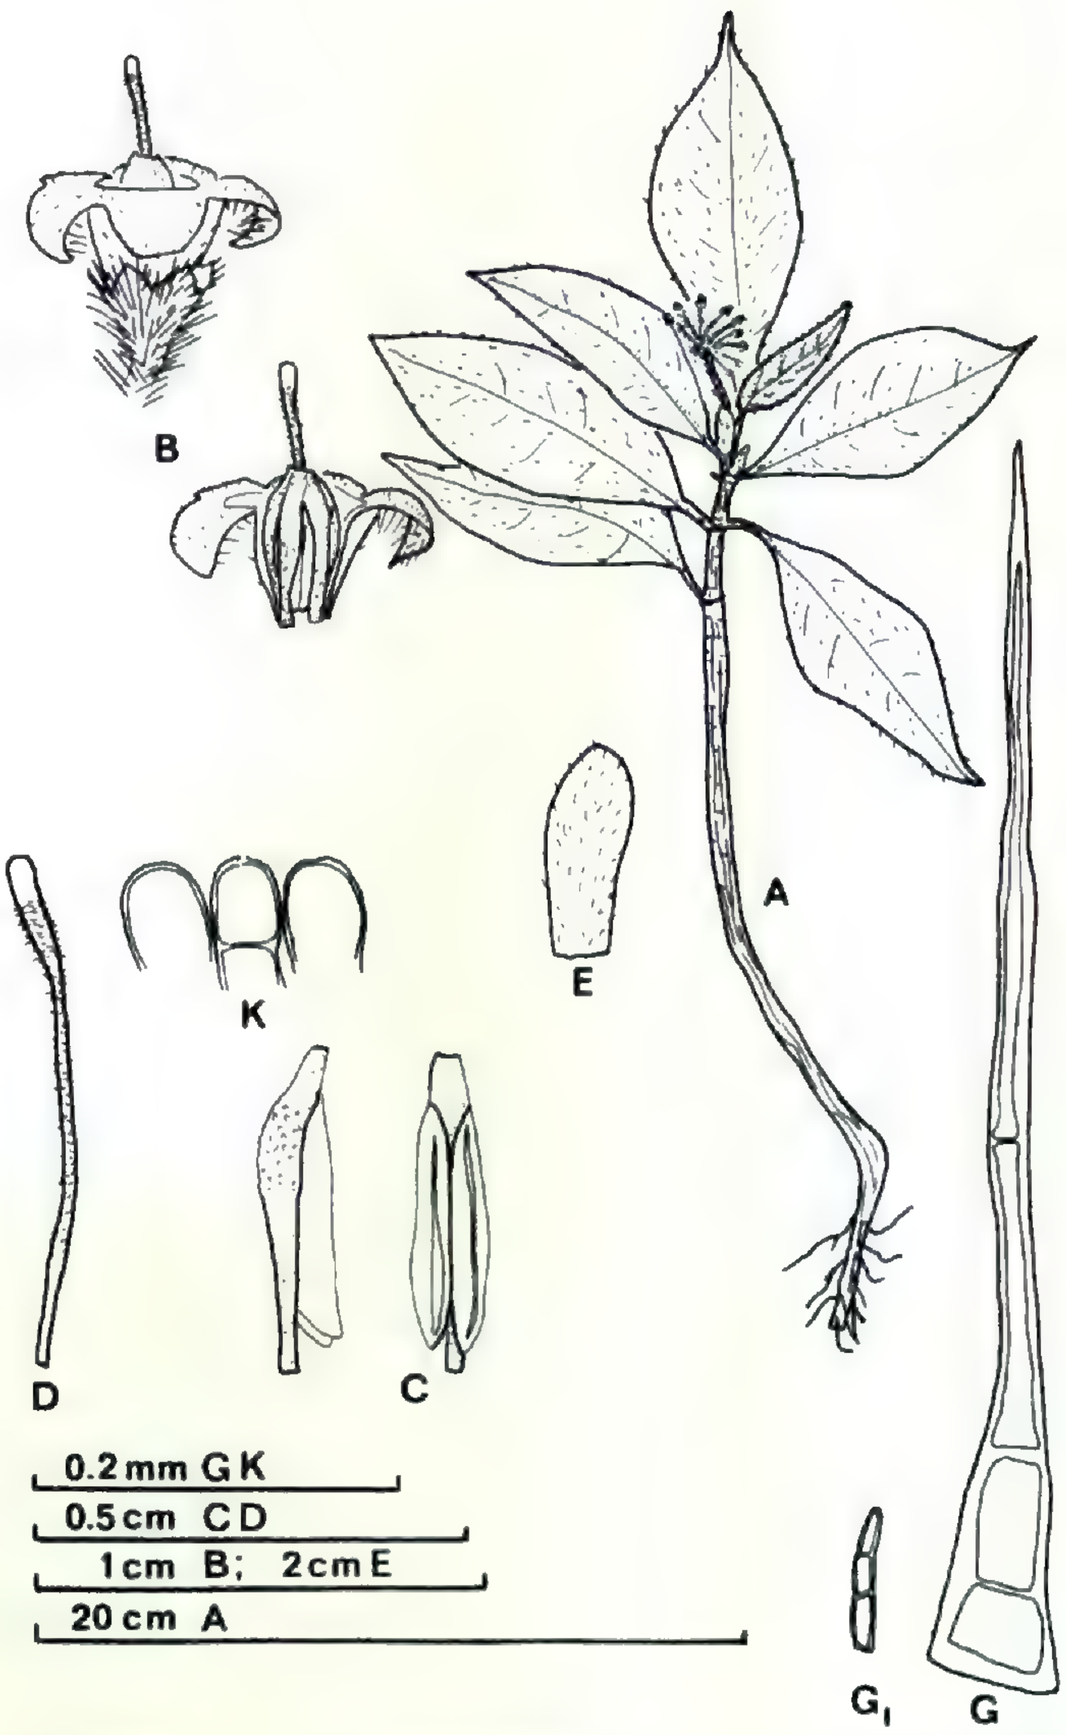

FIGURE 26. *Argostemma trichosanthes*.—A. Habit.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—G. Hair from outer surface of the corolla.—G_1. Hair from inner surface of the corolla.—K. Papillae or hairs from the connectives. From *Winkler 781* (NY).

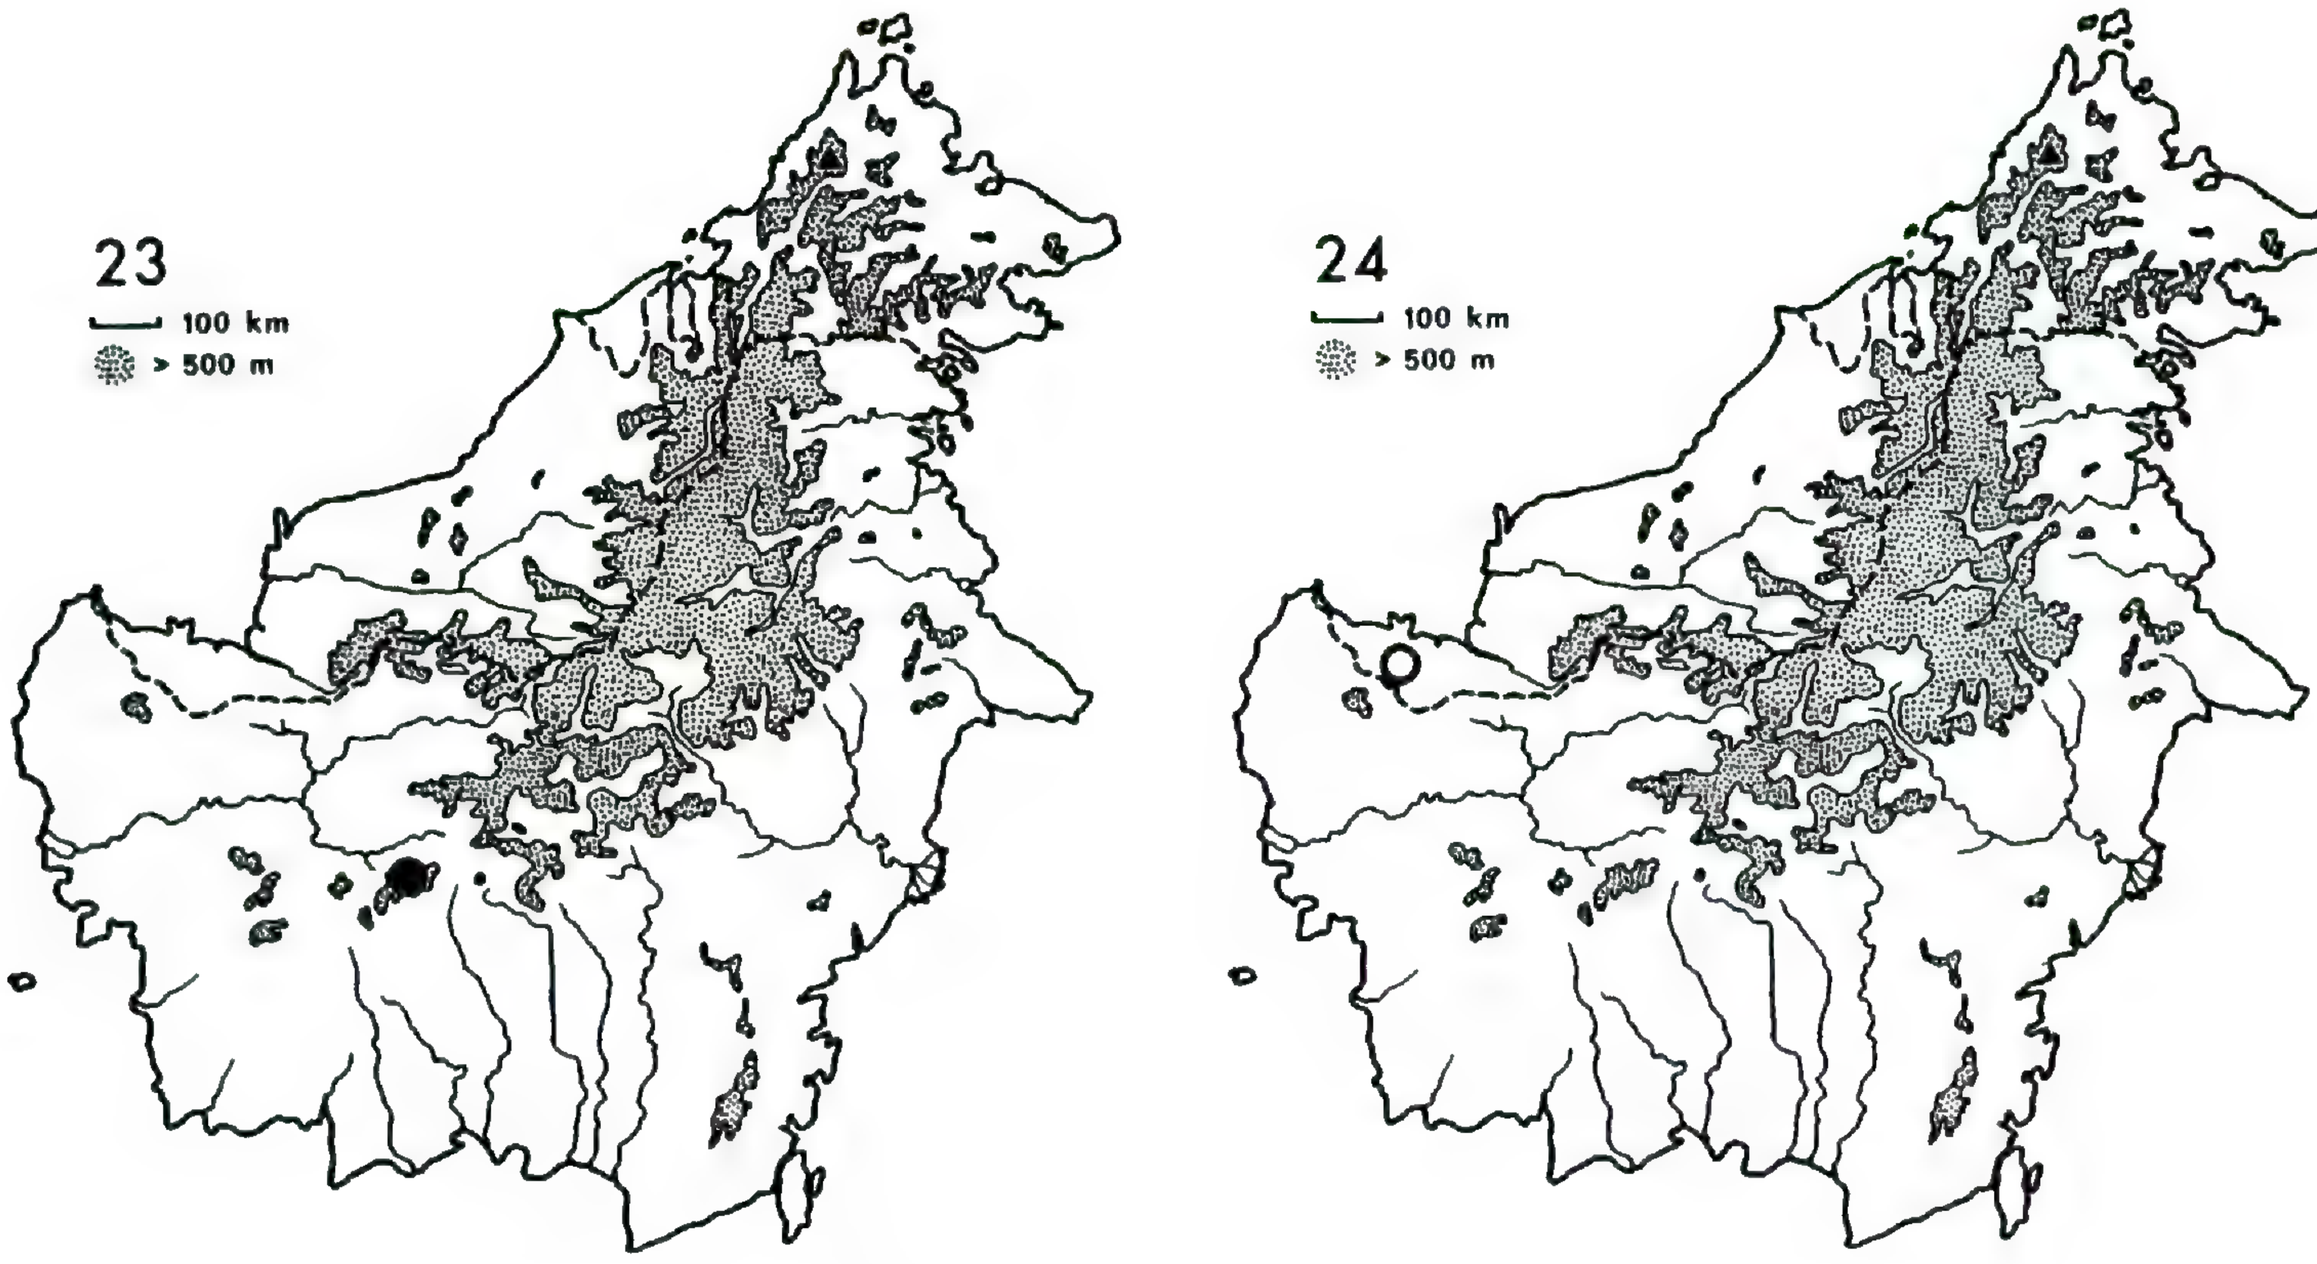
This rare species has been collected only four times. Haviland and Hose made the first collection, noting only the locality as Baram. Different collectors recorded it as growing on limestone. Anderson said "frequent in crevices on vertical limestone rocks." My collection is from low altitude in a limestone area. The earlier collections were all determined as *A. borragineum* because of the equal, opposite leaves. However, the stems, stipules, anthers, and style are quite different. It is close to *A. havilandii* and shares various characters with this species: lower stems pale brown to grayish, these having papery to corky surfaces and elevated ridges; anther shape; and clavate pubescent styles. However, *Argostemma calcicolum* differs from *A. havilandii* by its denser pubescence even on the peduncles and stipules, isophyllous leaves, and the upper part of the connectives distinctly papillose to hairy. The hairs on the connectives are not homologous to those on the anthers of *A. psychotrioides*, which has smooth connectives but papillose to hairy thecae and apical appendages. In *A. calcicolum* these parts are smooth.

Additional specimens examined. BORNEO. SARAWAK: 4th Div., Gunong Subis, 1972, *Anderson S31672* (A); 4th Div., Penkalan Lobang Niah Caves, *Burtt & Woods 2005* (E); 4th Div., Baram, 1894, *Haviland & Hose 3409* (K).

23. Argostemma trichosanthes Merr., Mitt. Inst. Allg. Bot. Hamburg 7: 280. 1937. TYPE: West Borneo. Bidang Menabei, 700 m, 1924, *Winkler 781* (holotype, HBG; isotype, NY). Figure 26.

Erect, densely pubescent, isophyllous herb. Stem ca. 25 cm, unbranched, densely pubescent, lower and older parts pale brown with elevated corky to papery longitudinal ridges and/or with transverse bars; internodes 7–15 mm. Leaves opposite, equal; stipules deciduous, 8–10 mm long, ovate, obtuse at apex; petiole 5–12 mm long, pubescent; lamina



MAPS 23, 24. Distributions in Borneo.—23. *Argostemma trichosanthes.*—24. *A. humifusum.*

6–11 × 3–5 cm, obovate to elliptic, basally cuneate to attenuate with the lobes equal, marginally serrulate, apically acuminate, herbaceous, pubescent on both sides; midrib and primary veins (ca. 8 pairs) distinct. Inflorescences 10–20-flowered, umbelliform, solitary; peduncle 1.5–3.2 cm, pubescent; bracts to 0.6 cm long, lanceolate to linear; pedicels 0.5–0.7 cm, pubescent. Flowers 5-merous; calyx lobes less than 1 mm long, triangular or ovate, acute, pubescent; corolla 3–5 mm long, cleft to about ½, externally pubescent, internally papillose to pubescent only on the lobes; lobes ovate to triangular, recurved. Stamens ca. 3.5 mm long, coherent, the anther cells free, the apical appendages connate; anther cone ovoid to shortly ovoid, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅕ the anther length, thick, coriaceous, smooth; connective coriaceous, distinct, papillose in upper part. Style ca. 6 mm long, pubescent, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma trichosanthes is known only from the type. It was collected at Bidang Menabei on Kalimantan at 700 m.

Argostemma trichosanthes is close to *A. havilandii* and *A. calcicolum*, with which it shares the stem characters pale brown to gray, papery to corky, and with elevated ridges on the lower stems. With *A. calcicolum* it shares opposite isophyllous leaves. *Argostemma trichosanthes* is easily distinguished by its dense indumentum. The upper part of the stems, particularly the younger leaves and most parts of the inflorescences, are densely covered by stiff, long, thick-walled hairs.

24. Argostemma humifusum W. Smith, Notes Roy. Bot. Gard. Edinburgh 8: 317. 1915. TYPE: Borneo. Sarawak: Gunong Bayat (= ?Gunong Sebayat near Kuching), 1914, *native collector D131* (holotype, E; isotypes, E, K, SAR). Figure 27.

Erect, anisophyllous herb. Stem 6–16 cm, slightly branched or unbranched, glabrous; internodes 4–15 mm. Leaves opposite, very unequal; stipules persistent, 6–8 mm long, cordiform or broadly ovate, acuminate at apex. Larger leaves of the anisophyllous pairs with finely pubescent petioles 5–16 mm long; lamina 4–9 × 2–4.5 cm, obovate, basally acute to obtuse with the lobes unequal, marginally serrulate, apically shortly acuminate, membranaceous to herbaceous, pubescent on both surfaces; midrib and primary veins (6–10 pairs) distinct. Nanophyllous leaves persistent, 5–10 mm long, ovate. Inflorescences 5–10-flowered, umbelliform, solitary or a few together; peduncle 1.7–2.5 cm, glabrous; bracts very small, ovate to linear; pedicels 0.3–0.6 cm, with a few hairs. Flowers 5-merous; calyx lobes less than 1 mm long, ovate, acute, pubescent; corolla ca. 4 mm long, externally pubescent, internally glabrous(?). Stamens ca. 3 mm long, coherent; anther cells free,

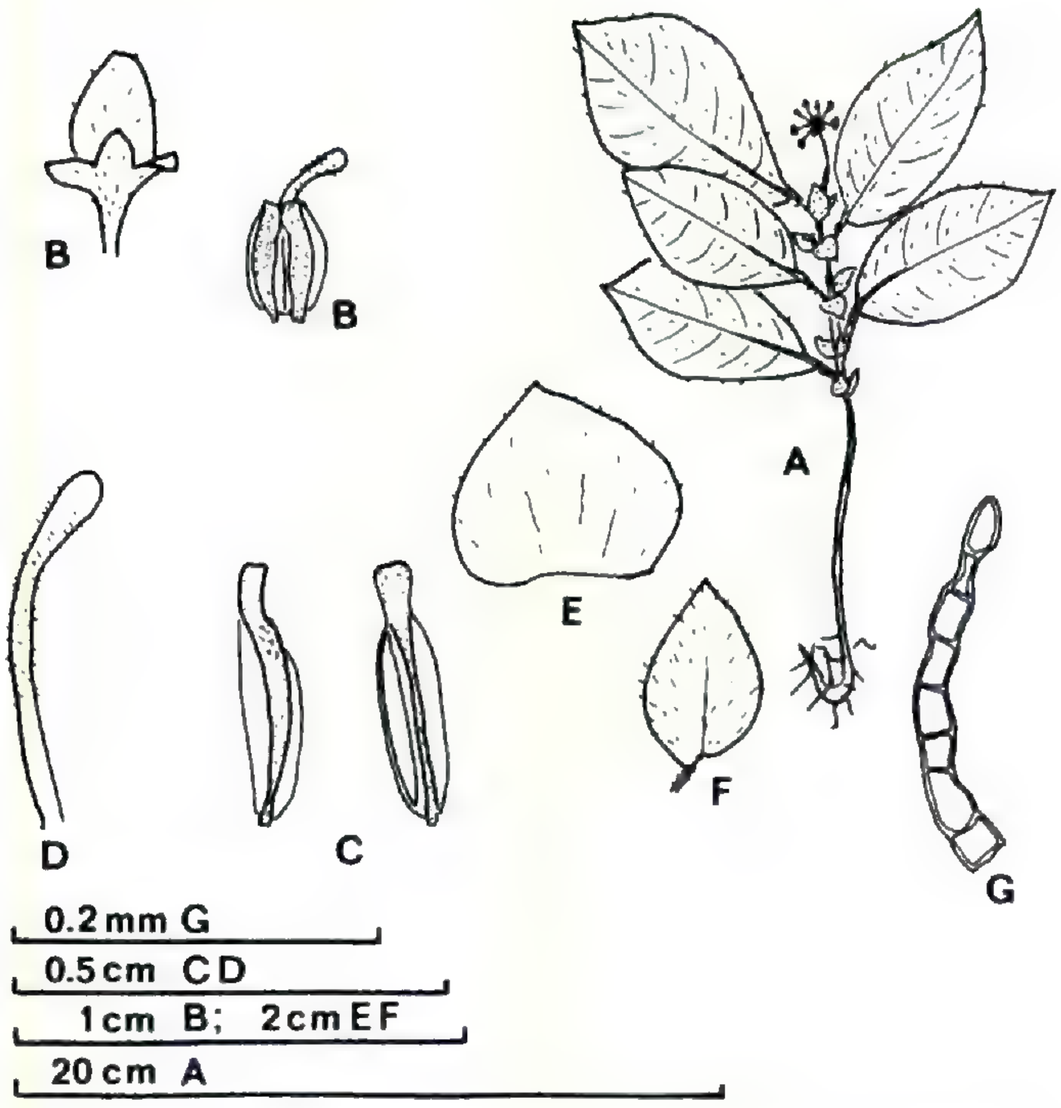


FIGURE 27. *Argostemma humifusum*.—A. Habit.—B. Flower bud, and anther cone.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—G. Hair from outer surface of the corolla. From *native collector D131* (E, K).

the apical appendages connate; anther cone ovoid to shortly ovoid, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅕ the anther length, thick, coriaceous, smooth; connective coriaceous, distinct, papillose in upper part. Style ca. 5 mm long, glabrous to pubescent, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma humifusum has been collected twice, but nothing was recorded about its habit or habitat.

This species is characterized by its broad, obovate leaves and large cordiform stipules. Because of incomplete material, I do not know the shape of the corolla. It has a thin corolla similar to those generally cleft halfway into recurved lobes. Internally the corolla seems to be glabrous, but among the other species with thin corollas, the lobes are usually pubescent. The upper part of the connective is probably papillose to pubescent as in *A. calcicolum* and *A. trichosanthes*.

Additional specimen examined. BORNEO. SARAWAK: Kutein, 1865–1867, *Beccari 150* (K, L).

25. Argostemma psychotrioides Ridley, J. Bot. 65: 38. 1927. TYPE: Borneo: *Haviland 689* (holotype, K; isotype, SAR). Figure 28.

Erect, anisophyllous herb. Stem 10–100 cm, slightly branched or unbranched, finely pubescent

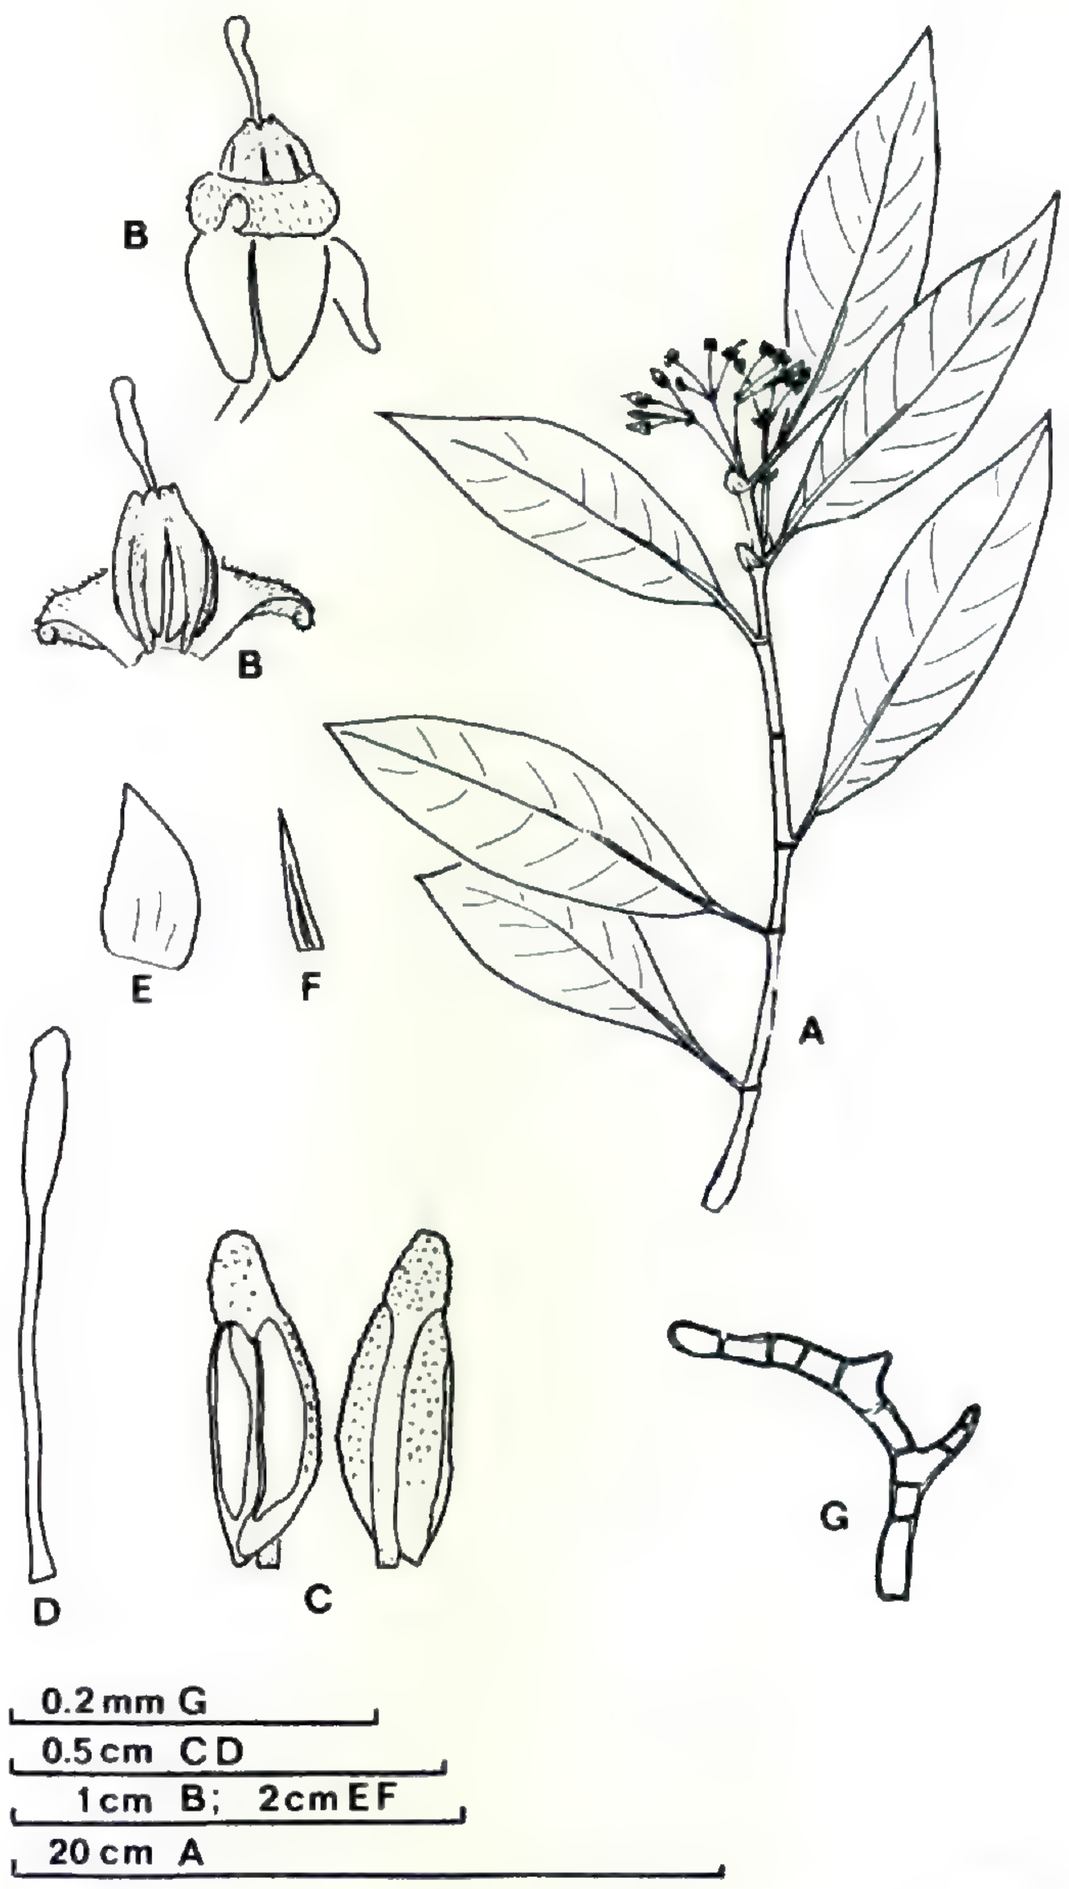

FIGURE 28. *Argostemma psychotrioides*.—A. Flowering branch.—B. Flower.—C. Anthers.—D. Style.—E. Stipule.—F. Nanophyllous leaf.—G. Hair from outer surface of the corolla. From *Burtt & Martin 4991* (E).

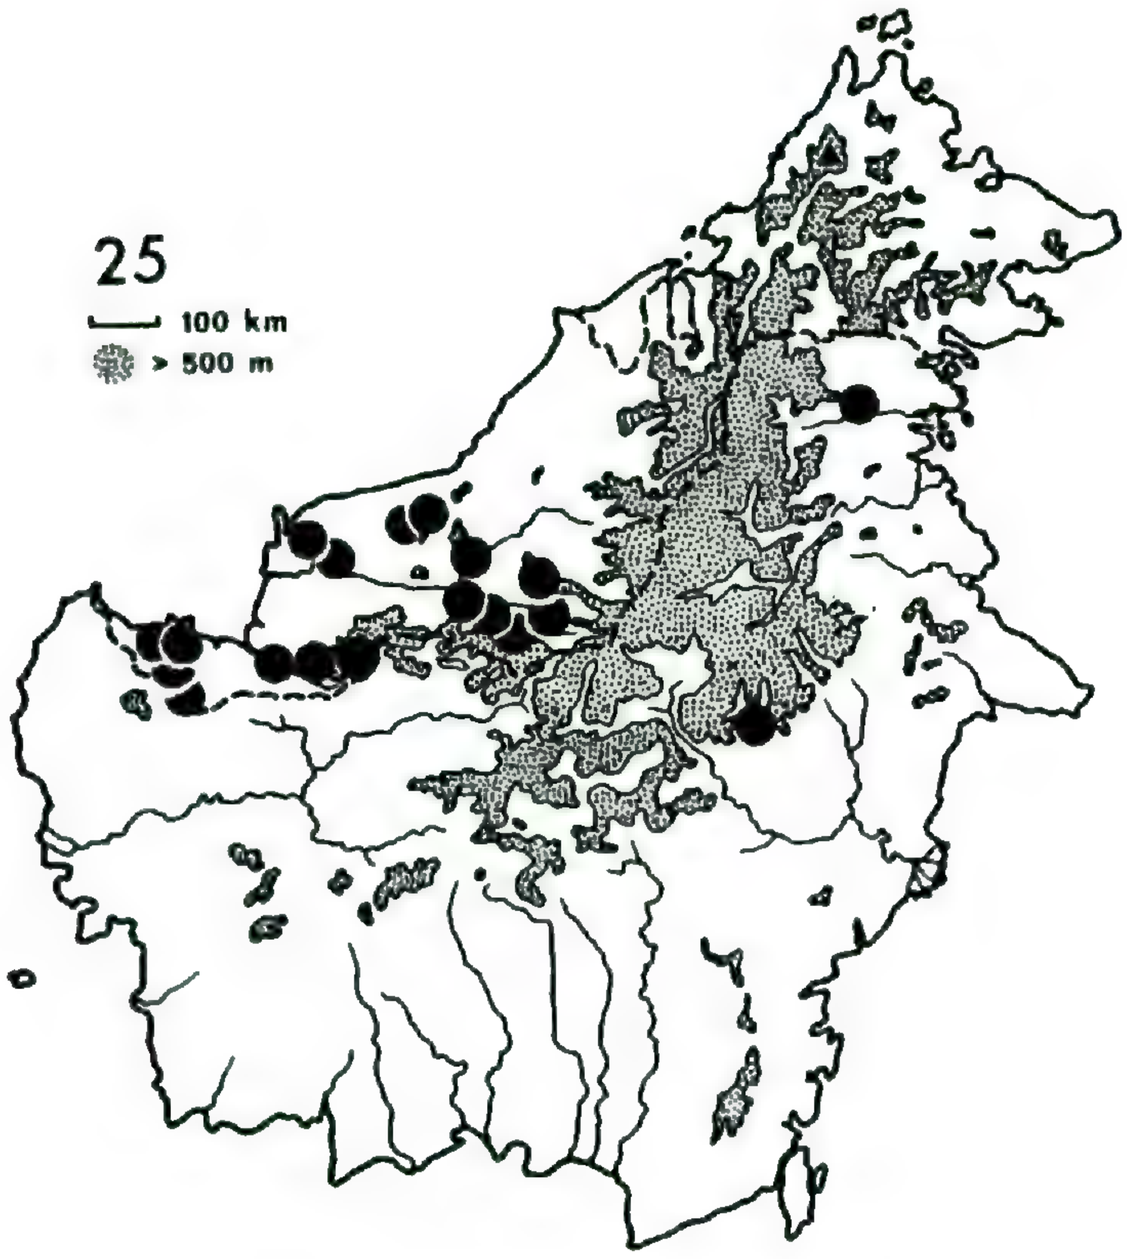
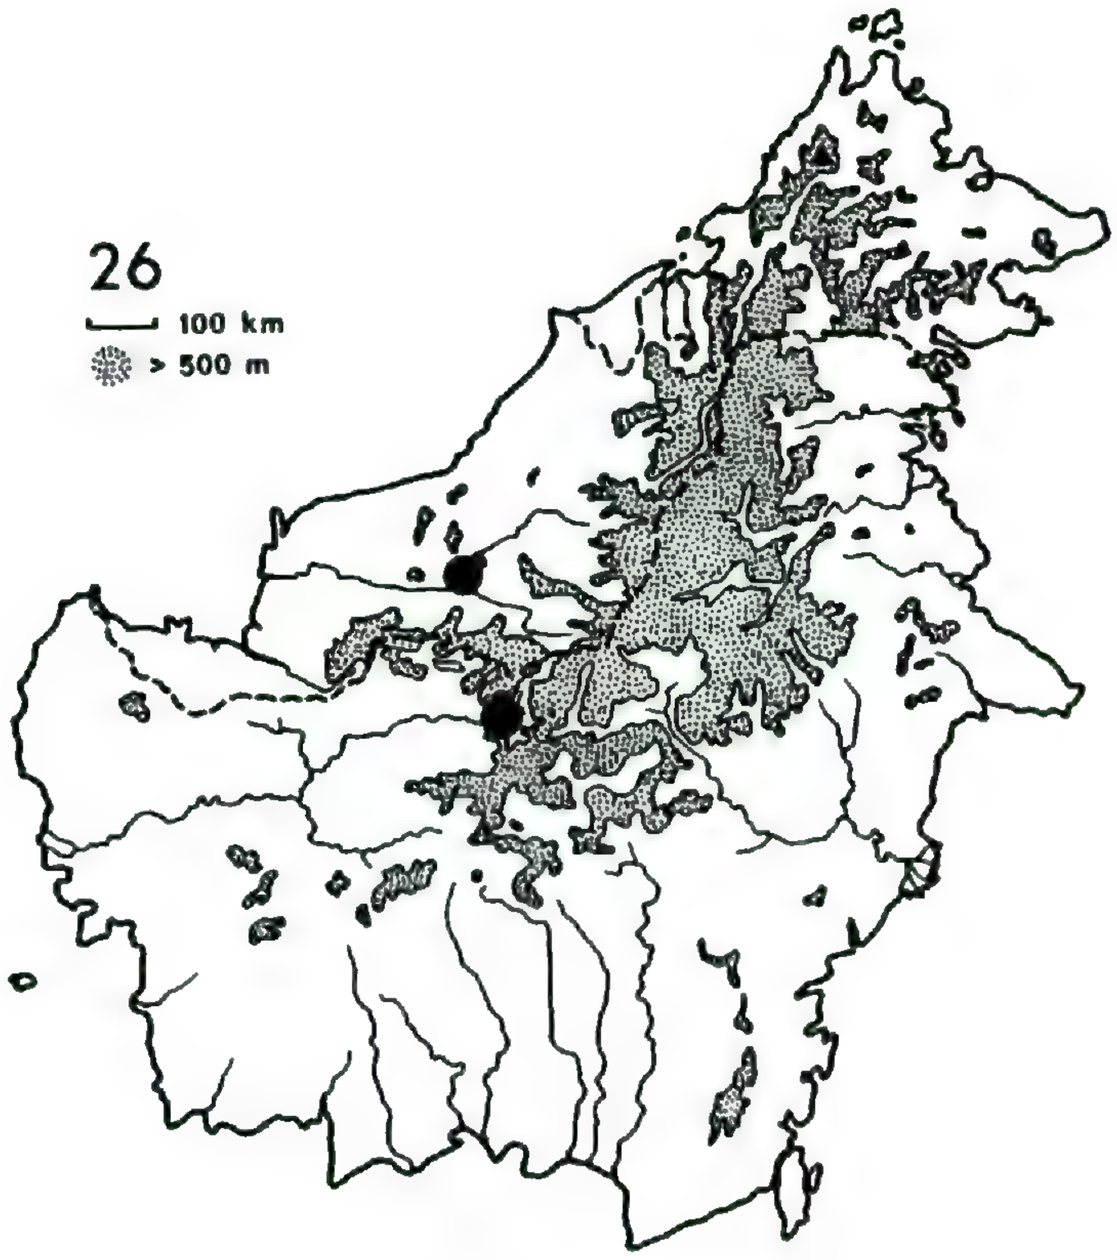
or glabrous; internodes 7–30 mm long. Leaves opposite, very unequal; stipules deciduous, 6–20 mm long, ovate to lanceolate, acuminate at apex; larger leaves of the anisophyllous pairs with finely pubescent or glabrous petioles 3–19 mm long; lamina 5–18 × 1–6 cm, obovate or oblanceolate to ovate or lanceolate, basally acute to attenuate with the lobes equal, marginally entire, apically acuminate or rarely acute to obtuse, herbaceous, glabrous above, glabrous to finely pubescent on the veins below; midrib and primary veins (7–15 pairs) distinct. Nanophyllous leaves deciduous, 5–13 mm long, ovate to lanceolate, acuminate. Inflorescences 3–30-flowered, umbelliform, rarely with lateral branches to corymbiform, solitary or a few together; peduncle 1–4 cm, pubescent or glabrous; bracts 0.7 cm long, ovate or lanceolate to linear; lateral branches, if present, to 3 cm, pubescent; pedicels 0.5–1.5 cm, pubescent. Flowers 5-merous; calyx





MAPS 25, 26. Distributions in Borneo.—25. *Argostemma psychotrioides.*—26. *A. variegatum.*

lobes 2–6 mm long, subspatulate or ovate to oblong, acute, reflexed and pressed against the ovary concealing it even before anthesis, pubescent to glabrous; corolla 3–5 mm long, cleft to about ½ its length, externally pubescent, internally papillose to pubescent only on the lobes; lobes ovate to triangular, recurved. Stamens 2–4 mm long, coherent; anther cells free, the apical appendages connate; anther cone ovoid to shortly ovoid, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅓ the anther length, thick, coriaceous, papillose; connective coriaceous, distinct, generally smooth. Style 4–7 mm long, glabrous or rarely with a few hairs, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma psychotrioides is found mostly at altitudes less than 250 m, although it occurs up to 1,000 m. It grows in shady, wet places on exposed roots and pneumatophores in swampy forests and on boulders in streams. It also grows under drier conditions on limestone and at higher altitudes in mossy forests.

It is easily identified by its strongly reflexed calyx lobes which in living material are green with white margins and tips. The corolla is thin and pubescent to densely pubescent and has recurved lobes. The anther cone is low, pale yellow to creamish. Only the apical appendages are connate, and the thecae are free. The thick apical appendages and the back of the thecae are distinctly papillose to hairy, while the connectives are smooth (cf. *A. trichosanthes*). There is little variation in the characters of the flowers, but a few specimens (*Bremer 1730, 1744, 1748*) from the 7th Division have shorter calyx lobes. The shape and size of the leaves as well as the occurrence of hairs are variable and do not correlate with distribution patterns.

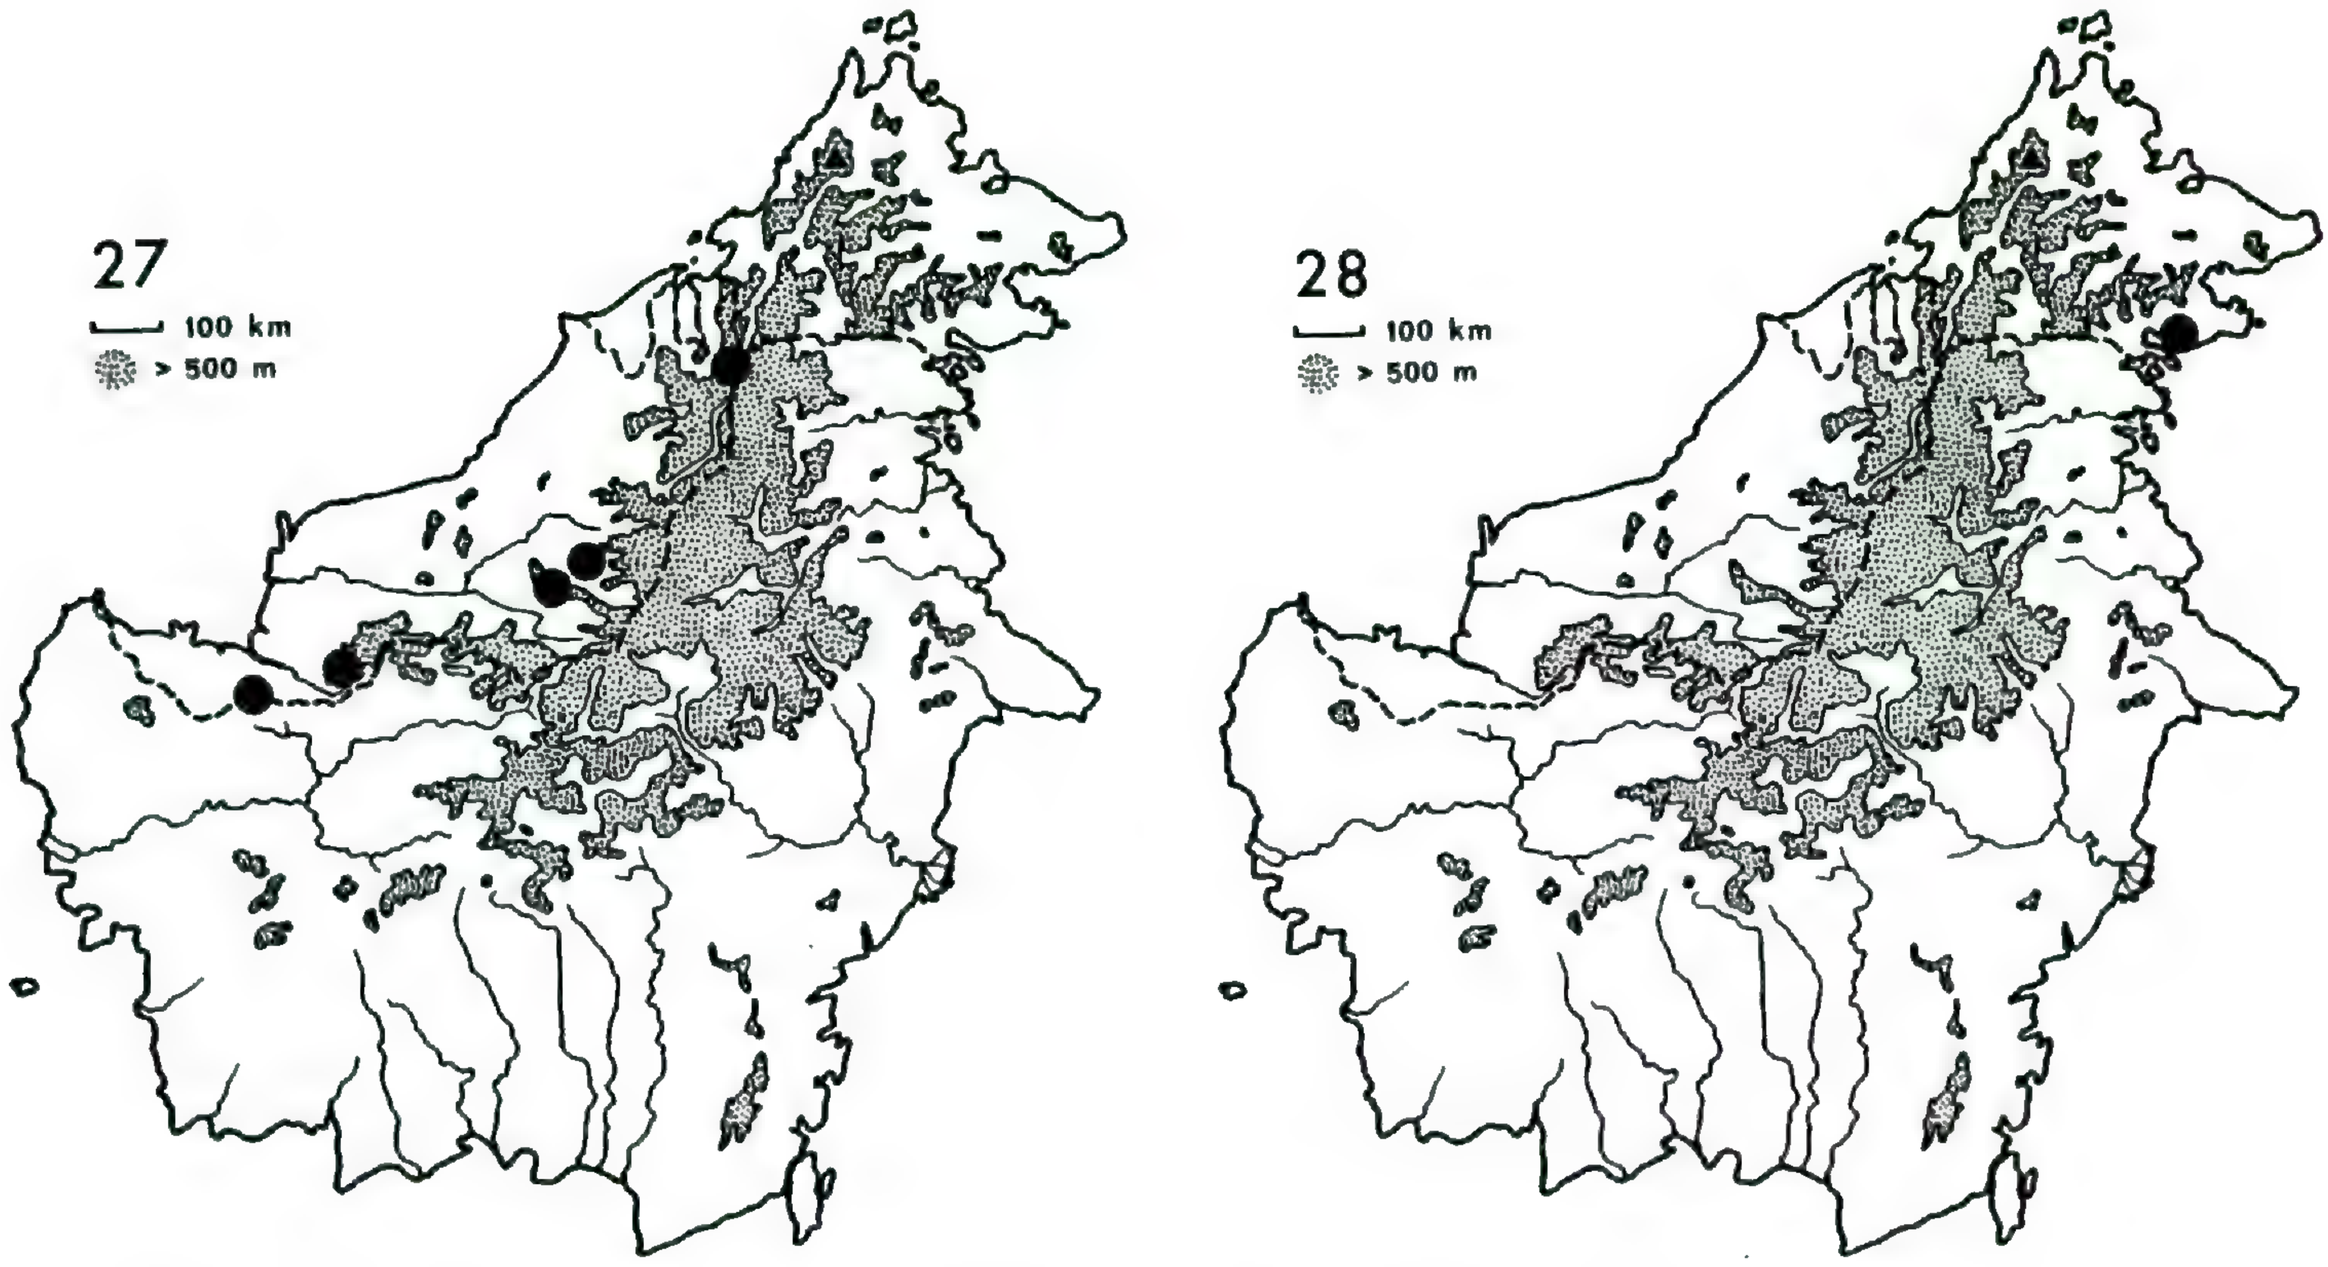
26. Argostemma variegatum Merr., Mitt. Inst. Allg. Bot. Hamburg 7: 280. 1937. TYPE: West Borneo. Nanga Era, 100 m, 1925, *Winkler 1561* (holotype, HBG; isotype, NY). Figure 29.

Creeping anisophyllous herb. Stem 10–20 cm, slightly branched or unbranched, pubescent; internodes 3–17 mm long. Leaves opposite, very unequal; stipules persistent, 3–6 mm long, lanceolate, acuminate at apex; larger leaves of the anisophyllous pairs with pubescent petioles 2–5 mm long; lamina 3.5–7 × 1.4–3.4 cm, obovate to oblanceolate, basally rounded or obtuse with the lobes unequal, marginally entire or serrulate, apically obtuse or obtuse with a point, herbaceous, glabrous above, finely pubescent on the veins and margins below; midrib and primary veins (7–9 pairs) distinct. Nanophyllous leaves persistent, ca. 5 mm long, linear, petiolelike. Inflorescences ca. 7–flowered, umbelliform, solitary; peduncle 1–3 cm, pubescent or almost glabrous; bracts ca. 0.5 cm long, linear; pedicels 0.5–0.9 cm, pubescent. Flowers 5(or 6)-merous; calyx lobes 3–4 mm long, subspatulate or ovate to oblong, acute, reflexed and pressed against the ovary concealing it even before anthesis, pubescent to glabrous; corolla ca. 3 mm long, cleft to about ½, externally pubescent, internally papillose to pubescent only on the lobes; lobes ovate to triangular, recurved. Stamens 2.5–3 mm long, coherent; anther cells free, the apical appendages connate; anther cone ovoid to shortly ovoid, straight; filaments very short, equal, straight; sacs opening completely longitudinally; apical appendage ¼–⅙ the anther length, thick, coriaceous, papillose; connective coriaceous, distinct, generally smooth. Style ca. 5 mm long, glabrous, with a clavate stigma, long-exserted. Fruit without furrows or ribs.

Argostemma variegatum has been collected on steep soil banks in disturbed primary forest and in primary forest at ca. 100 m. Its habit is like that of *A. elatostemma* and *A. densifolium*, that is, creeping with anisophyllous leaves, the larger ones with unequal leaf-base lobes. The stems, petioles, and veins are distinctly pubescent. The flowers,



MAPS 27, 28. Distributions in Borneo.—27. *Argostemma bryophilum*.—28. *A. neurocalyx*.

however, are different from the above species; they are similar to those of *A. psychotrioides*. The calyx lobes are long and reflexed, the corollas are cleft to about half their length into pubescent, recurved lobes. The original collection has silvery mottled leaves while the other does not (perhaps due to drying). *Argostemma variegatum* is close to *A. psychotrioides*; the similarities to *A. elatostemma* are superficial.

Additional specimen examined. BORNEO. SARAWAK: 7th Div., Bukit Raya, 1969, *Smith S28234* (A, K, L).

27. Argostemma bryophilum Schumann in Schumann & Lauterb., Nachträge zur Flora der Deutschen Schutzgebirge in der Südsee. 393. 1905. TYPE: from Kaiser Wilhelmsland, not seen. Figure 30.

Small, creeping to erect, generally isophyllous herb. Stem 2–10 cm, unbranched or slightly branched, densely pubescent; internodes 3–20 mm. Leaves opposite, generally equal; stipules persistent, to 4 mm long, broadly ovate to cordiform, acute to obtuse at apex; petiole 3–11 mm long, pubescent; lamina 1.5–4.2 × 0.6–1.9 cm, ovate or elliptic to lanceolate, basally cuneate to attenuate with the lobes equal, marginally serrulate or entire, apically acute to acuminate or obtuse with a point, membranaceous, pubescent on both surfaces, below most prominent on the veins; midrib and primary veins (5–8 pairs) distinct. Inflorescences 1–2-flowered, solitary or a few together; peduncle 3–6 mm long, almost glabrous; bracts ca. 4 mm long, lanceolate or triangular; pedicels ca. 7 mm long, pubescent. Flowers 5-merous; calyx lobes 2–4 mm long, triangular, acuminate; corolla cleft to near the base, glabrous on both surfaces; lobes 5–7 mm long, ovate to lanceolate, acuminate, spreading. Stamens 4–5 mm long, coherent; anther cells and apical appendages connate except for the most apical part; anther cone ovoid, straight; filaments short, equal, straight; sacs of different length, opening completely longitudinally; apical appendage very short, glabrous; connective ± distinct, papillose. Style 4–5.5 mm long, glabrous, with a clavate stigma, shortly exserted. Fruit without furrows or ribs.

Argostemma bryophilum grows on wet rocks, boulders, or banks among mosses from 350 to 1,500 m.

It is the first species described in a large complex from New Guinea and the Philippines with more than ten taxa. Bakhuizen f. (pers. comm.) has treated the complex as a single species. All details of the complex are not known and so I have only accepted one variable species. This is the first report from Borneo. The collections from Borneo are all rather similar, with the exception of *Axelius 112A*, which has anisophyllous leaves. The Borneo specimens form a homogenous group and may in the future be recognized as a distinct taxon separate from the New Guinea and Philippine members of the complex. It is a small plant with pale green, thin, and hairy leaves. With one exception, all

collections have isophyllous, opposite leaves, very pubescent stems, and cordiform, glabrate stipules. The flowers are solitary, starlike and with long, bright yellow anther cones. The thecae distinguish this species from all others: the inner pollen sac of each theca is only ca. half as long as the outer one, which is almost as long as the whole anther, and there is no distinct apical appendage. The stigma is distinctly clavate with papillae covering the clavate area. In all flowering specimens (five of the seven known specimens), the stigma is totally covered by germinated pollen grains. The pollen is probably from the same flower, because the stigma is partly covered by the apical anther parts. I have not found more than a few pollen grains on the stigmas of any other species. Probably this species is autogamous.

Specimens examined. BORNEO. SARAWAK: 1st Div., Sabal, 350 m, 1979, *Bremer 1664* (S, SAR); 2nd Div., Bukit Sadok, 1982, *Axelius 112A* (S); 5th Div., Bakelalan, 4,000 ft., 1955, *Brooke 10406, 10464* (BM, L); 7th Div., Hose Mts., Bukit Salong, 1980, *Burtt 12733* (E); Bukit Sanpandai, 4,500 ft., 1980, *Burtt 12800* (E); 7th Div., Bukit Dema, 1978, *Burtt 11328* (E).

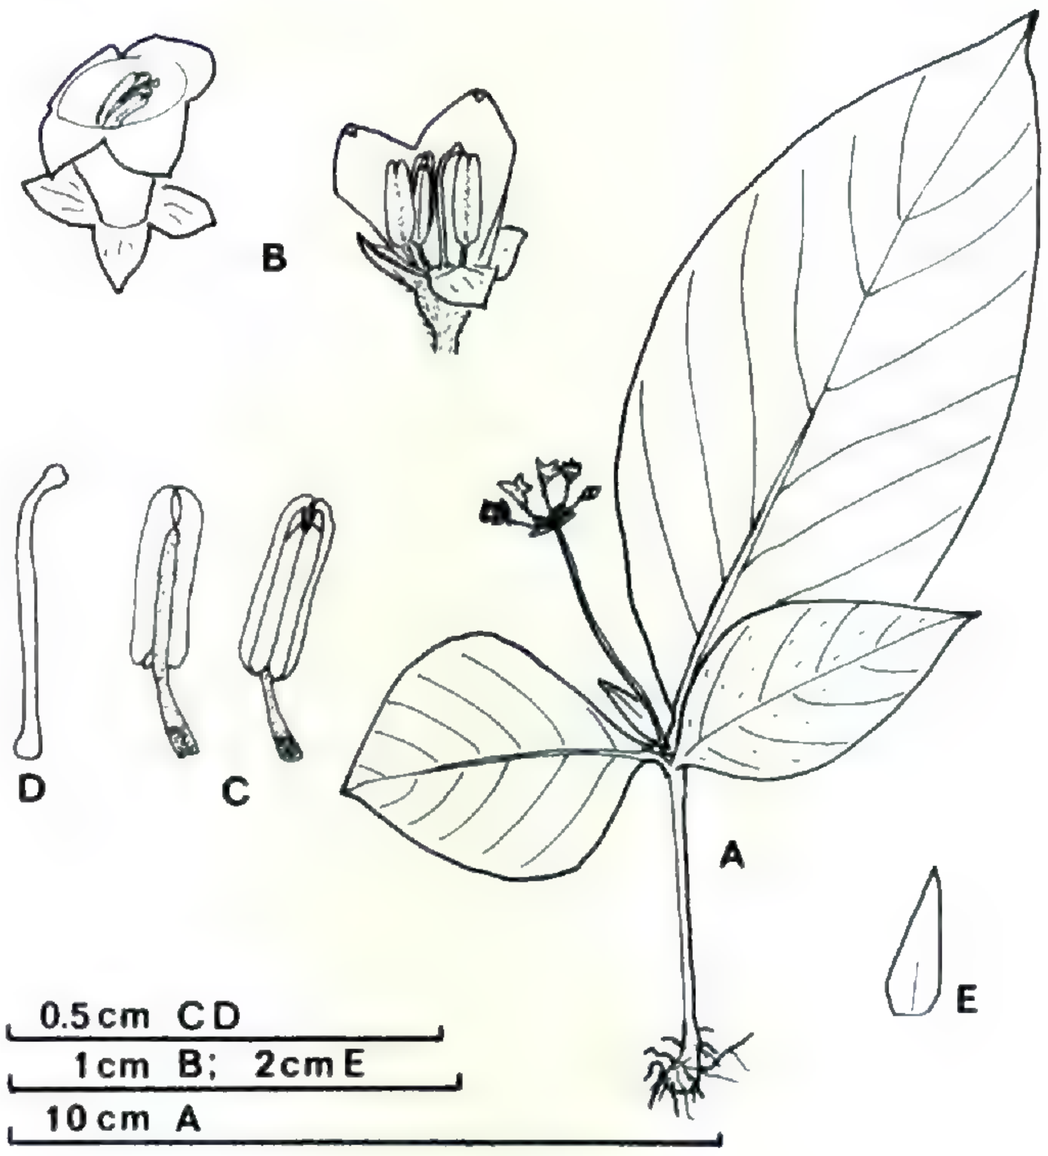


FIGURE 31. *Argostemma neurocalyx.*—A. Habit.—B. Flower.—C. Anthers.—D. Style.—E. Stipule? From *Elmer 21138* (G, SING).

28. Argostemma neurocalyx Miq., Ann. Mus. Bot. Lugd.-Bat. 4: 229. 1869. TYPE: Sumatra?: *Junghuhn s.n.* (holotype, U). Figure 31.

A. platyphyllum Merr., Univ. Calif. Publ. Bot. 15: 275. 1929. TYPE: British North Borneo: Tawao, 1922–1923, *Elmer 21138* (lectotype, K; Bakh. f. in herb., confirmed here; isolectotypes, BO, BR, G, GH, NY, S, SING, U, UC, US).

Erect anisophyllous herb with an apical rosette of 2–4 leaves. Stem 4–8 cm, unbranched, glabrous or glabrate, without distinct internodes. Leaves verticillate, compressed in an apical rosette; stipules(?) persistent, 4–9 mm long, lanceolate, acuminate at apex; petiole absent; lamina 2–15 × 12.7–7.6 cm, suborbicular or ovate to elliptic, basally obtuse or shortly attenuate and equal, marginally entire, apically acute to shortly acuminate, membranaceous, pubescent above, below with a few hairs on the veins; midrib and primary veins (7–9 pairs) distinct. Inflorescences 4–15-flowered, umbelliform, solitary or a few together; peduncle 2.3–5.5 cm, glabrous; bracts to 0.5 cm long, ovate; pedicels 0.4–0.7 cm, pubescent. Flowers 4(or 5?)-merous; calyx lobes 1–2 mm long, ovate to broadly ovate, acute, glabrous; corolla ca. 5 mm long, cleft less than ⅓ its length, glabrous on both surfaces; lobes ovate to triangular, erect. Stamens ca. 3 mm long; free, not forming a cone; filaments ca. ½ as long as the anthers, equal, straight; sacs opening by pores; without apical appendages; connective distinct, smooth. Style ca. 4 mm long, glabrous, with a capitate stigma, exserted. Fruit without furrows or ribs.

Merrill based *A. platyphyllum* on one collection by *Elmer*; no specimen is indicated. All specimens are suitable for lectotypification. Bakhuizen f. (in herb.) has selected the K specimen, and I follow his choice.

Argostemma neurocalyx was collected just once on Borneo, by Elmer, near Tawau, and was described by Merrill as *A. platyphyllum*. The protologue says "a succulent erect herb in dense forests on moss-covered basaltic rocks over which water trickles." It is not only the sole collection of the species on Borneo, it is also the only collection representing this section of the genus from Borneo. Possibly it was erroneously labeled in the herbarium by Elmer or Merrill. However, it is an easily distinguished species with two or four verticillate, slightly unequal leaves. On dry specimens, the leaves are very thin and membranaceous. It is difficult to determine from the herbarium specimens if there are stipules or just smaller leaves. The umbelliform inflorescences have long glabrous peduncles, rather large, ovate bracts, and pubescent pedicels. The flowers are tetramerous and campanulate, and the corolla lobes seem to be reflexed. The stamens are free with long filaments and connectives ending below the thecae. The pollen sacs open by pores formed by short, broad slits in the upper part of each pollen sac. The pores (slits) are placed between the sacs of each theca. As the dorsal sacs are larger

than the ventral sacs, only the pores of the dorsal ones can be seen (from the inside of the flower), and the pores of the ventral sacs are hidden by the longer dorsal sacs.

STUDIES IN NEOTROPICAL PALEOBOTANY. VII. THE LOWER MIOCENE COMMUNITIES OF PANAMA—THE LA BOCA FORMATION[1]

Alan Graham[2]

ABSTRACT

Thirty-nine palynomorphs have been identified from among 54 forms recovered from the lower Miocene La Boca Formation in the Canal region of Panama. These are ascomycete cleistothecia, the dinoflagellates *Spiniferites* and *Operculodinium*, *Lycopodium*, *Selaginella*, *Cyathea*, *Pteris* (types 1 and 2), cf. *Antrophyum*, other trilete fern spores (types 1–3), monolete fern spores (types 1–5), Gramineae, Palmae (*Attalea*, *Manicaria*, and *Synechanthus* types), *Ilex*, cf. *Aguiaria*, cf. *Ceiba*, *Pseudobombax*, *Alchornea*, *Alfaroa/Engelhardia*, *Crudia*, *Utricularia*, Malpighiaceae (types 1–5), Malvaceae, *Rhizophora* (constituting 67–88% of five samples counted), Rubiaceae (types 1 and 2), and *Pelliciera*. The flora is estuarine in aspect, and consistent with three other lower Miocene assemblages (Uscari, Culebra, Cucaracha), reflects low-lying volcanic islands fringed seaward by mangroves, with freshwater fern and palm swamp marshes in the lowlands and versions of the tropical wet, tropical moist, and premontane forests on the adjacent slopes. There is no palynological evidence for communities of drier to arid aspect (including savannahs) or of high altitudes; elevations of 1,200 to 1,500 m would accommodate all taxa present in the La Boca and other fossil floras. The affinity of the flora is distinctly with Central America and areas to the north. With the exception of *Crudia*, all genera occur in the modern vegetation of Panama, and consequently the paleoclimate, in agreement with Tertiary paleotemperature curves, was similar to that prevailing today in coastal, lowland, and moderate-altitude tropical habitats in southern Central America.

The La Boca Formation is the third in a series of three stratigraphically and lithologically similar formations from the geologically complex Canal region of Panama yielding well-preserved fossil pollen and spores. The Culebra Formation is oldest (basal) and is overlain by the Cucaracha Formation. The La Boca does not anywhere lie directly on the Cucaracha, but it interfingers (viz., is contemporaneous) with the Pedro Miguel Formation, which overlies the Cucaracha elsewhere in the Canal region. Age estimates are based primarily on molluscan (Woodring, 1957–1982) and ostracod (Van den Bold, 1972, 1973) data which suggest an early Miocene age for the three formations.

The La Boca outcrops along both sides of the Panama Canal from the Pacific entrance to the Las Cascadas Reach. The sediments were deposited in an estuarine environment and include an alternating sequence of mudstones, siltstones, sandstones, lignitic shales, tuffs (waterlain volcanic ash), and limestones typical of that environmental setting. The presence of the coralliferous Emperador limestone member in the lower part of the formation and *Rhizophora*-containing lignitic shales indicate deposition in warm temperate to tropical, shallow seas and in adjacent coastal, brackish-water habitats.

Fifty-four samples were collected from two exposures of the La Boca Formation along the Las Cascadas Reach in September 1967 (latitude 9°04′N, longitude 79°40′W; ground elevation 52.7 m). Locality A (samples 1–26) was at Canal marker 1600 (1766 in the new marking system), and locality B (samples 27–54) at markers 1622 (1788), 1625 (1791), and 1627 (1793). Since that time the Canal has been widened from 90 m to 155 m, and compared with the present physiography, the 1967 samples were collected about 25 m up and 60 m out over the present Canal. The beds dipped back into the slope at a 20–25° angle so that now

[1] The author gratefully acknowledges information provided by William Elsik (Exxon Company, U.S.A.) and William Evitt (Stanford University) on the fungi and dinoflagellates. Research was supported by National Science Foundation grant BSR-8500850.

the same lignite layers are nearly at water level. Other details of the collecting site and geology of the area are summarized in Graham et al. (1985: 495–502).

Materials and Methods

Extraction and processing techniques are described in Graham (1985). Slides are labeled according to locality, sample number, and slide number (e.g., Pan A 5-1). Of the 54 samples collected, 20 contained fair to well-preserved palynomorphs (locality A—5, 14, 16, 17, 19, 20, 21; locality B—27, 28, 29, 30, 33, 34, 35, 45, 46, 47, 50, 52, 54). Location of the specimens on the slides is by England Slide Finder coordinates (e.g., ESF C-29). The tabulations in Table 1 are based on five representative samples (14, 16, 20, 21, 50) containing diverse and well-preserved palynomorphs. All materials are deposited in the palynology collections at Kent State University.

Systematics

Thirty-nine palynomorphs have been identified from the La Boca Formation (Table 1) in addition to 15 others that cannot presently be identified (unknowns 1–15). Most of the specimens have been recovered from other Tertiary formations in the Gulf/Caribbean region and discussed in previous publications, hence the material presented here is synoptic. These formations and references are as follows: Gatuncillo (middle(?) to late Eocene, Panama; Graham, 1985); San Sebastian (middle to late Oligocene, Puerto Rico; Graham & Jarzen, 1969); Uscari (early Miocene, Costa Rica; Graham, 1987a, b); Culebra (early Miocene, Panama; Graham, 1988a), and Cucaracha (early Miocene, Panama; Graham, 1988b). Present ranges of the modern analogs within the Neotropics and ecological data are based on field observations, personal communication with specialists, and the literature, especially Croat (1978), D'Arcy (1987), Hartshorn (1983), Tryon & Tryon (1982), and Woodson & Schery (1943–1980). Terminology for vegetation types follows Holdridge (1947; Holdridge et al., 1971), used by Croat (1978) and Hartshorn (1983) for describing the plant communities of Panama and Costa Rica. In instances where the modern analogs extend into South America, their altitudinal ranges and community affiliations may differ slightly from their Central American occurrences. The data for Central America are considered first in paleocommunity and paleoenvironmental reconstruction of the La Boca flora, since communities in South America are more distant and were isolated from Central America until about 3 Ma.

FUNGI

Ascomycete cleistothecium (Fig. 1). Flattened, circular, multicellular, cells cubical, 6 × 9 μm, outer and some lateral walls of peripheral (marginal) cells thickened, center opaque (solid?), cells disrupted along outer edge, forming slitlike opening 35 μm long (attachment scar?); 124 μm.

Reproductive structures of the Plectomycetes group of ascomycete fungi are frequent in Gulf/Caribbean Tertiary deposits but never in large numbers. Although entire specimens are relatively rare, fragments are present in almost all samples. Another type with radially aligned cells and marginal spines was recovered from the lower Miocene Uscari sequence of Costa Rica (Graham, 1987a, fig. 1).

PYRROPHYTA

Spiniferites (Figs. 2, 3). These dinoflagellate cysts, as fossils referable to *Spiniferites*, are common in the Tertiary and extend back to the Early Cretaceous. They are produced by some species of the extant *Gonyaulax* group (Evitt, pers. comm., 1987).

Operculodinium centrocarpus (Fig. 4). This is also a common Tertiary form produced by the modern *Gonyaulax grindleyi* (= *Protoceratium reticulatum*) and a frequent associate of *Spiniferites* in the Miocene. According to Evitt (pers. comm., 1987), "These two cyst types are common constituents of Tertiary nearshore sediments. They occur, virtually to the exclusion of other forms, in the Miocene Monterrey Formation in California (*Spiniferites* much the more abundant), and together with a very rich associated assemblage in the Calvert Formation along the east coast. It would be entirely plausible to find them in estuarine deposits of Miocene age virtually anywhere. No examples of *Spiniferites*, which has a very distinctive and easily recognized morphology (at least at the generic level), have been found in fully freshwater sediments."

LYCOPODIACEAE

Lycopodium (Fig. 5). Amb triangular, apices rounded; trilete, laesurae straight, narrow, ca. 20–22 μm long, extending to spore margin, inner margin entire, distal surface with numerous circular punctae ca. 1 μm diam., proximal face laevigate; wall 1–1.5 μm thick; 40 μm.

These spores are similar to those of *L. reflexum*

TABLE 1. Identification and numerical representation of fossil palynomorphs from the lower Miocene La Boca Formation. Figures are percentages based on counts of 200 specimens from four samples at locality A (14, 16, 20, 21) and one sample at locality B (50). Minus sign (−) indicates specimens are present in the sample but were not encountered in counts of 200. The counts do not include clusters of 20 or more grains of *Rhizophora* found in sample 14, or *Pelliciera* in sample 16.

Lam. and *L. linifolium* L. presently occurring in moist shaded habitats in Panama. They have been recovered from the Culebra, Uscari, and Paraje Solo formations, although the Uscari specimens have thicker walls (3–4 μm vs. 1–1.5 μm).

SELAGINELLACEAE

Selaginella (Fig. 6). Spherical, amb circular to oval-triangular; trilete, laesurae frequently obscured by dense sculpture, arms variously developed and spores often appearing monolete, straight, narrow, ca. 20–24 μm long, extending nearly to spore margin; echinate, echinae short (ca. 2–3 μm), occasionally curved, dense, bases broad; wall ca. 2 μm thick (excluding echinae); 30–32 μm.

Selaginella is widespread in moist, shaded habitats in the Neotropics. The spores occur in low numbers in the Gatuncillo, San Sebastian, Uscari, Culebra, Cucaracha, and Paraje Solo formations.

CYATHEACEAE

Cyathea (Figs. 10, 13). Amb oval-triangular, apices rounded; trilete, laesurae straight, narrow, 19–21 μm long, extending to or nearly to spore

FIGURES 1–7. Fossil spores from the La Boca Formation, Panama.—1. Ascomycete cleistothecium, Pan B 27-1, ESF C-29, 3–4.—2, 3. *Spiniferites* sp., Pan A 14-1a, ESF R-46, 1–3.—4. *Operculodinium centrocarpus*, Pan A

margin, inner margin entire, bordered by lip 2–3 μm wide with punctae 1 μm diam.; distal surface finely punctate, proximal surface more laevigate near laesurae; wall 1.5–2 μm thick; 32–36 μm.

Tryon & Tryon (1982: 204) noted that the classification of tree ferns differs among various authors and that the name *Cyathea* has been used to include nearly all members of the family. The labels on reference slides used for identification often reflect this confusion, especially between *Cyathea* and *Alsophila*. A further complication is that the lip surrounding the laesurae is difficult to observe on some fossil specimens because of preservation and/or orientation. According to recent illustrations by Gastony & Tryon (1976) and Tryon & Tryon (1982), trilete, micropunctate forms with a lip often bordered by punctae are referred to *Cyathea*, while forms with a laevigate surface beneath the perine belong to *Alsophila*. Laevigate spores of similar size and morphology lacking the lip and bordering punctae are produced by several extant genera (e.g., species of *Adiantum*). Following this classification, *Cyathea* spores are known from the Culebra, Cucaracha, La Boca, and Paraje Solo formations (as *Alsophila* in the latter; Graham, 1976, figs. 16–18). *Alsophila* is known from the Gatuncillo Formation (Graham, 1985, fig. 10, as trilete fern spore type 1) and from the Paraje Solo Formation (Graham, 1976, fig. 19, as *Cyathea*).

In Central America *Cyathea* grows primarily in low rain forests, montane forests, and cloud forests, usually between 1,500 and 2,000 m.

PTERIDACEAE

Pteris. *Pteris* is a genus of about 250 species, with some 55 occurring in the Neotropics from northern Mexico (Nuevo León) and Florida to Argentina and Chile (Tryon & Tryon, 1982: 334). It usually grows at altitudes below 2,000 m in wet, cloud, or gallery forests. Spores are frequent but not abundant in the Gatuncillo, San Sebastian, Uscari, Culebra, Cucaracha, and Paraje Solo formations.

Type 1 (Figs. 8, 9). Amb oval-triangular, apices rounded, margin entire to slightly undulating; trilete, laesurae straight, narrow, inner margin entire, 23–25 μm long, extending to spore margin; wall with coarse irregular verrucae on distal surface, proximal surface more laevigate, hyaline marginal flange 12–15 μm wide; 62–68 μm.

Type 2 (Figs. 11, 12). Smaller (40–42 μm), the marginal flange narrower (4–5 μm wide), and the verrucae smaller and more numerous.

VITTARIACEAE

Cf. Antrophyum (Fig. 14). Amb triangular, apices rounded; trilete, laesurae relatively small in relation to spore diam., straight, narrow, 12–16 μm long, extending ca. ⅔ distance to spore margin, inner margin entire; laevigate; wall ca. 1.5 μm thick; 50–52 μm.

Antrophyum is represented by about 10 species in the Neotropics, growing in cloud and rain forests usually at elevations between 100 and 1,500 m from Mexico (Hidalgo) through Central America and the Antilles to northern Argentina and southeastern Brazil (Tryon & Tryon, 1982: 360). The spores are similar to those of *Acrostichum aureum* L. (cf. Tryon & Tryon, 1982, figs. 49.10, 12 and 51.8), a species expected in the La Boca and other estuarine formations because it grows in brackish mangrove swamps. The spores of *A. aureum* in our reference material (nine collections) have a granular, scabrate sculpture, while those of *Antrophyum* are more laevigate. The distinction is difficult among fossil specimens, and it is possible that both genera are represented in Gulf/Caribbean Tertiary deposits. Since the fossils are laevigate, however, they are referred to cf. *Antrophyum*. Similar spores are known from the Gatuncillo, San Sebastian (not figured in Graham & Jarzen, 1969), Culebra, Cucaracha, and Paraje Solo (as an unknown in Graham, 1976, fig. 227) formations.

OTHER TRILETE FERN SPORES

Several trilete fern spores were recovered for which biological affinities could not be determined. Three of the more distinctive ones are described below.

Type 1 (Fig. 7). Amb oval-triangular, apices rounded, margin entire; trilete, laesurae straight, narrow, inner margin entire, 12 μm long, extending ca. ¾ distance to spore margin; laevigate; wall 1.5 μm thick; 29–32 μm.

These spores are similar to those of several ferns, including *Adiantum*, and cannot be referred to any

one genus. They are also known from the Uscari sequence of Costa Rica (Graham, 1987a, fig. 30).

Type 2 (Fig. 15). Amb oval-triangular to circular; trilete, laesurae straight, narrow, 17–20 μm long, extending ca. ¾ distance to spore margin, inner margin entire; finely reticulate; wall 1.5 μm thick; 45–48 μm.

Type 3 (Figs. 16, 17). Amb triangular, trilete, laesurae straight, narrow, 12–14 μm long, extending to or nearly to spore margin, prominent lip (partially folds?), inner margin entire; distal surface divided into low, irregular, verrucaelike segments by short, sinuous furrows, proximal surface more laevigate; wall 2–3 μm thick; 31–33 μm.

MONOLETE FERN SPORES

Reniform, monolete fern spores are common in all Tertiary formations studied for the Gulf/Caribbean region. They are produced by members of the Blechnaceae, Polypodiaceae, and Pteridaceae and range from Paleozoic to Recent. Five types illustrate the range in sculpture and size. Type 1 (Fig. 18; 45 × 32 μm) is laevigate; type 2 (Fig. 19; 70 × 46 μm) is finely verrucate; type 3 (Fig. 20; 69 × 51 μm) has numerous, small, densely arranged verrucae; type 4 (Fig. 21; 42 × 36 μm) is coarsely verrucate; and type 5 (Fig. 22; 54 × 36 μm) has prominent, widely scattered, peglike verrucae.

GRAMINEAE

Spherical, amb circular; monoporate, pore circular, 2 μm diam., inner margin entire, annulus ca. 2 μm wide, outer margin entire; tectate, wall ca. 2 μm thick; psilate to faintly scabrate; ca. 30 μm (folded) (Fig. 23).

The Gramineae are stenopalynous, and the specimens cannot be referred to any single genus. Grass pollen continues to be rare or absent in Gulf/Caribbean Tertiary deposits studied to date, with only a few grains previously reported from the Culebra and Paraje Solo formations. Specimens are known in the stratigraphic literature as *Monoporites annulatus* and range from the Paleocene (Brazil) to Recent (Muller, 1981, 1984).

PALMAE

Although several surveys of modern palm pollen are available (e.g., Ferguson, 1986; Thanikaimoni, 1970), it is still difficult to identify Gulf/Caribbean Tertiary specimens. The palms were a prominent component of the vegetation, and three types are recognized for the La Boca Formation.

Attalea type (Fig. 24). Wedge-shaped, with greatest diam. near pole; amb ca. rectangular; monocolpate, colpus straight, narrow, 19–22 μm long, inner margin entire to minutely dentate; scabrate; tectate, wall ca. 1.5 μm thick; 43–47 × 25–29 μm.

Attalea is a genus of about 40 species occurring in South America, the West Indies, and the Old World tropics, with one species (*A. allenii* H. Moore) listed for Panama (D'Arcy, 1987), where it grows at elevations up to ca. 1,000 m.

Manicaria type (Figs. 25–27). Prolate, with greatest diam. at or near equator; monocolpate, colpus straight to slightly sinuous, narrow, 30–42 μm long, extending nearly entire length of grain, inner margin entire; finely reticulate (diam. of lumen 1 μm or slightly less); tectate-perforate, wall ca. 1 μm thick; 36–48 × 21–30 μm.

Manicaria is a tree up to 10 m tall, with three species in the Antilles, Central America, and South America (fide Bailey, 1943), where it often occurs in dense groves in wet places. Similar pollen is known from the Gatuncillo and Culebra formations.

Synechanthus type (Figs. 28, 29). Prolate; monocolpate, colpus straight, narrow, 30–42 μm long, extending entire length of grain, inner margin entire; microreticulate; tectate-perforate, wall 1.5–2 μm thick; 36–48 × 30–38 μm.

Synechanthus grows in Panama at low elevations in the tropical moist, premontane wet, and premontane rain forests (Croat, 1978: 178). Similar pollen occurs in the Culebra Formation.

AQUIFOLIACEAE

Ilex (Fig. 31). Oblate-spheroidal, amb oval to circular, tricolporoidate, colpi straight, 18 μm long, equatorially arranged, meridionally elongated, equidistant, inner margin diffuse, pores obscure, diam. ca. 2–3 μm, circular, situated at midpoint of colpus; intectate, clavate, wall 3 μm thick; 27 × 18 μm.

In Central America *Ilex* commonly grows at mid altitudes in moist to slightly drier habitats. It is a frequent component of Gulf/Caribbean Tertiary microfossil floras in low percentages and has been recovered from the Gatuncillo, San Sebastian, Uscari, Culebra, Cucaracha, and Paraje Solo formations.

BOMBACACEAE

The pollen of several Bombacaceae are distinct (Tsukada, 1964; Nilsson & Robyns, 1986), but other generalized types cannot be referred to any one genus (see listings in Muller, 1981: 46–48). There is also some overlap with the closely related families Sterculiaceae and Tiliaceae, and in fossil deposits types are recovered that do not match exactly any extant members of the complex (Graham, 1976, figs. 248–255). It is possible that some unidentified pollen represents extant species not yet collected or extinct taxa from early speciation after introduction into the Caribbean region. Further studies are needed on the pollen morphology of modern forms, including newly described taxa, and a complete assessment should be made of fossil types.

Bombacaceae are prominent members of neotropical forests, and the pollen is frequent but not abundant in Tertiary sediments. Muller (1981: 46–48) listed the oldest occurrence of this family as Maestrichtian (uppermost Cretaceous) from the southeastern United States and cited other records supporting Wolfe's (1975) suggestion that the family originated in eastern North America and subsequently spread to South America and Africa where it diversified. In the Caribbean region it first appears in the Paleocene of northern South America (*Bombacacidites annae* = *Bombax ceiba* type; Germeraad et al., 1968: 277), and in our material, pollen of the family occurs in the San Sebastian Formation and Uscari sequence.

Cf. Aguiaria (Fig. 30; cf. modern pollen illustrated by Nilsson & Robyns, 1986, fig. 7f, g). Oblate, amb circular; tricolpate, colpi short (8–10 μm apex to equator), equatorially arranged, meridionally elongated, equidistant, inner margin minutely dentate, bordered by narrow margo ca. 1.5–2 μm wide; finely reticulate; tectate-perforate, wall ca. 2 μm thick; 30–34 μm.

Cf. Ceiba (Fig. 34; cf. modern pollen illustrated by Nilsson & Robyns, 1986, fig. 11I). Oblate, amb circular; tricolpate, colpi short (13–15 μm apex to equator), equatorially arranged, meridionally elongated, equidistant, inner margin entire to minutely dentate, bordered by narrow margo ca. 2–3 μm wide; reticulate, muri smooth, slightly sinuous, narrow (ca. 0.5–1 μm), lumina polygonal, 4–5 μm diam. at poles, smaller toward equator; tectate-perforate, wall ca. 1.5 μm thick; 56–60 μm.

Pseudobombax (Fig. 35; cf. modern pollen illustrated by Nilsson & Robyns, 1986, fig. 6I). Oblate, amb triangular, sides slightly concave, apices rounded; tricolpate, colpi short (8–10 μm apex to equator), equatorially arranged, meridionally elongated, equidistant, inner margin entire, bordered by faint narrow margo ca. 1 μm wide; reticulate at poles, muri smooth, straight to occasionally curved, narrow (ca. 1 μm), lumina polygonal, ca. 3 μm diam., becoming minutely reticulate around apices; tectate-perforate, wall 1.5–2 μm thick; 54–56 μm.

Pseudobombax is a tree to 25 m tall distributed from Nicaragua to Brazil and Peru. In Panama it typically occurs at lower elevations in the tropical moist forest but is also found in the premontane moist, tropical wet, and locally from the tropical dry forest (Croat, 1978: 591).

EUPHORBIACEAE

Alchornea (Fig. 32). Oblate, amb circular; tricolpate, colpi straight, 6–8 μm long (apex to equator), equatorially arranged, meridionally elongated, equidistant, extending within 6–7 μm of pole, inner margin entire, operculum distinct; psilate to faintly scabrate; tectate, wall 1.5 μm thick; 18–20 μm.

Pollen of *Alchornea* is frequent in low numbers in Gulf/Caribbean Tertiary deposits. It ranges from the lower and middle Eocene (Colombia; González Guzmán, 1967) to Recent (Muller, 1981). Its ecology and distribution have been summarized by Graham (1987a) based on Croat (1978) and Webster & Burch (1967). In Central America *Alchornea* grows in the tropical moist, premontane wet, and premontane rain forest typically at elevations between 300 and 2,000 m.

JUGLANDACEAE

Alfaroa/Engelhardia (Fig. 33). Oblate, amb oval-triangular; triporate, pores circular, ca. 2 μm diam., inner margin entire, equatorially arranged, equidistant; psilate; tectate, wall 1.5–2 μm thick; 20–25 μm.

These trees are distributed from Mexico through Central America, usually associated with lower- to mid-altitude temperate forests. Pollen occurs in the Gatuncillo, San Sebastian, Cucaracha, and Paraje Solo formations.

LEGUMINOSAE—CAESALPINIOIDEAE

Crudia (Fig. 37, 38). Prolate; tricolporoidate, colpi narrow, straight, 25 μm long, extending nearly entire length of grain, equatorially arranged, meridionally elongated, equidistant, pore area faint, circular, situated at midpoint of colpus; distinctly and coarsely striate, striae generally oriented parallel to long axis of grain, surface psilate, margins entire, occasionally appearing beaded from underlying pores in foot layer/endexine; tectate but with occasional separation between sculpture elements, wall 1.5 μm thick; 42–48 × 30–32 μm.

Crudia is a South American, mainly Amazonian, riverine tree of low altitudes (Cowan & Polhill, 1981: 131). Pollen ranges from the Eocene in northern South America (as *Striatocolpites catumbus*) and from the Paleocene in Africa (Muller, 1981). It occurs in Central America in the Gatuncillo and Cucaracha formations. Modern pollen has been studied by Graham & Barker (1981).

LENTIBULARIACEAE

Utricularia (Fig. 36). Oblate, amb circular; stephanocolpate, colpi 12–16, equatorially arranged, meridionally elongated, equidistant, 15–18 μm long, extending within 8–10 μm of pole, inner margin entire; psilate to faintly scabrate; tectate, wall 2 μm thick; 34–36 μm.

Utricularia is an annual or stoloniferous perennial, insectivorous, aquatic herb growing along the margins of freshwater lakes and rivers, swamps, and marshes from Florida to Mexico and south through the Antilles, Central America, and South America. It is represented by about 12 species in Panama (Taylor, 1976). Pollen also occurs in the Paraje Solo Formation.

MALPIGHIACEAE

Representation of the Malpighiaceae in the Gulf/Caribbean Tertiary is analogous to the Bombacaceae, wherein several types are present but many do not match exactly modern reference material or species illustrated in the literature. Generally similar modern forms include *Banisteria*, *Banisteriopsis*, *Bunchosia*, *Hiraea*, *Malpighia*, and *Mascagnia*; but since the specimens are slightly different, they are referred to types 1–5.

Type 1 (Fig. 39). Spherical, amb circular; periporate, pores circular, 3–4 μm diam., inner margin entire; scabrate; tectate, wall 5–6 μm thick; 42 μm.

The distinguishing features of this grain are the very thick wall and the absence of colpi connecting the pores.

Type 2 (Fig. 40). Spherical, amb circular; periporate, pores circular, 3 μm diam., inner margin entire, faint colpi with diffuse, granular margins connecting the pores; scabrate; tectate, wall 2 μm thick; 35 μm.

These specimens have moderately thick walls and faint connecting colpi.

Type 3 (Fig. 41). Spherical, amb circular; periporate, pores circular, 1.5–2 μm diam., inner margin entire, colpi with diffuse, granular margins connecting the pores; scabrate, some scabrae pointed; tectate, wall 2 μm thick; 36 μm.

The distinguishing features of type 3 are the moderately thick wall, distinct colpi, and some scabrae with pointed apices.

Type 4 (Fig. 42). Spherical, amb circular; periporate, pores circular, 3–4 μm diam., inner margin entire, colpi with diffuse granular margins connecting the pores; scabrate; tectate, wall 5 μm thick; 45 μm.

These specimens differ from the thick-walled type 1 by having distinct colpi.

Type 5 (Fig. 43). Spherical, amb circular; periporate, pores circular, 1.5 μm diam., colpi with diffuse granular margins connecting the pores, colpi and pores numerous, giving scalloped appearance to outer margin of grain; psilate; tectate, wall 5–6 μm thick; 37 μm.

These thick-walled specimens have numerous pores and colpi, and they are psilate.

MALVACEAE

Spherical, amb circular; apertures obscure, periporate(?), pores circular, small (ca. 1.5 μm), evenly

distributed, inner margins entire; echinate, echinae hyaline, straight, broad at the base, densely arranged, 5 μm long, decreasing to 2–3 μm on portions of the exine; psilate; tectate, wall 1.5–2 μm thick; 30 μm (Fig. 44).

This unusual specimen may be an aberrant form and cannot be identified to genus. The Malvaceae are represented in the Caribbean Tertiary by *Hampea/Hibiscus* (probably *Hibiscus tiliaceus* L.) in the Culebra Formation and are frequent in the Tertiary of northern South America (as *Echiperiporites estelae*, late Eocene to Recent).

RHIZOPHORACEAE

Rhizophora (Fig. 47). Prolate to prolate-spheroidal; tricolporate, colpi straight, 14–16 μm, equatorially arranged, meridionally elongated, equidistant, inner margin entire, costae colpi ca. 2–3 μm wide, pores elongated equatorially (colpi transversalis), 1 × 4 μm, constricted at midpoint of colpus; finely reticulate; tectate-perforate, wall 2–3 μm thick; 16–20 × 14–18 μm.

Pollen of *Rhizophora* has been recovered from the Gatuncillo, San Sebastian, Uscari, Culebra, Cucaracha, and Paraje Solo formations and comprises 90% or more of some samples. Its fossil record has been discussed by Langenheim et al. (1967), Leopold (1969), and Muller & Caratini (1977), and its occurrence in the Gulf/Caribbean Tertiary was summarized by Graham (1985: 519, 1987a). *Rhizophora* is indicative of coastal, brackish-water conditions in tropical to subtropical regions. It is known in the stratigraphic literature as *Zonocostites ramonae* and ranges from the late Eocene to Recent. In older Tertiary deposits in Latin America it is replaced by its presumed ecological equivalent *Brevitricolpites* of unknown biological affinity.

RUBIACEAE

The Rubiaceae are represented in the La Boca Formation by two similar pollen types typical of several extant genera. These tricolpate, densely sculptured forms are produced by *Anisomeris*, *Chomelia*, *Guettarda*, *Terebraria*, and others.

Type 1 (Fig. 45). Oblate to oblate-spheroidal, amb circular; tricolpate, colpi equatorially arranged, meridionally elongated, equidistant, short (4–5 μm apex to equator), often obscured by dense sculpture; reticulate, muri 1.5 μm wide, smooth, straight to occasionally curved or slightly sinuous, lumina 2–3 μm diam.; tectate-perforate, wall 2 μm thick; 26–36 μm.

Type 2 (Fig. 46). Similar to type 1 but is slightly larger (42–46 μm), and the muri are thicker (ca. 2–2.5 μm).

THEACEAE

Pelliciera (Figs. 48, 49). Oblate, amb circular; tricolporate, colpi equatorially arranged, meridionally elongated, equidistant, 20–26 μm, tapering to acute apex, inner margin entire, pore circular, 3–4 μm diam., situated at midpoint of colpus, inner margin entire; sculpture variable from finely to coarsely verrucate; tectate, wall 4 μm diam.; size variable, 40–60 μm.

Pelliciera is a small mangrove tree of lowland coastal areas from Costa Rica to northwest Colombia and Ecuador. In the Tertiary, however, it was widespread in the Gulf/Caribbean and is known from the lower middle Eocene Yellow Limestone Group of Jamaica, the middle(?) to late Eocene Gatuncillo Formation of Panama, the middle to late Oligocene San Sebastian Formation of Puerto Rico, the Oligo-Miocene Simojovel Group of Mexico, and from several localities in northern South America. Several anther-size clusters or fragments (Fig. 49) were recovered, indicating the plants grew in the immediate vicinity of the depositional basin. The presence of *Pelliciera* pollen in the La Boca Formation is one of the principal differences between that unit and the Culebra and Cucaracha formations. In the stratigraphic record it is known as *Psilatricolporites crassus* and ranges from the Eocene to Recent. Other details of the ecology and geologic record of *Pelliciera* have been summarized by Graham (1977).

UNKNOWNS

A number of specimens were recovered that could not be identified. Some of the more distinctive and/or abundant ones are illustrated and briefly described below.

Unknown 1 (Fig. 50). Spherical, amb circular; apertures obscure (nonaperturate?); echinate, echinae straight to slightly curved, dense, 2–3 μm long; wall 1.5 μm thick; 16 μm.

Unknown 2 (Fig. 51). This type is similar to unknown 1 but is slightly larger (22 μm), and the spines are shorter (1 μm) and blunt.

Unknown 3 (Fig. 52). Prolate, amb oval; monocolpate, colpus straight, 22 μm long, inner margin minutely dentate; reticulate, muri straight, smooth, 1.5 μm wide, lumina 1–1.5 μm diam., reticulum

becoming finer toward poles; tectate-perforate, wall 2 μm thick; 36 × 27 μm.

These monocot pollen grains may be palms but no exact match has been found.

Unknown 4 (Fig. 53). Prolate, amb oval; monocolpate, colpi straight, 28 μm long; reticulate, reticulum deep (columellae 3 μm long), muri straight, smooth, 1 μm wide, lumina 2 μm diam.; tectate-perforate, wall 3–4 μm thick; 40 × 30 μm.

Unknown 5 (Fig. 54). Prolate, amb oval; monocolpate, colpus 42 μm long, extending entire length of grain, inner margin entire; echinate, echinae straight, 1.5 μm long, moderately dense; tectate, wall 1–1.5 μm thick; 45 × 24 μm.

Unknown 6 (Figs. 55, 56). Oblate-spheroidal, amb circular; tricolpate, colpi often obscured by coarse sculpture elements, short (5–6 μm long), equatorially arranged, meridionally elongated, equidistant; coarsely verrucate; tectate, wall 3 μm thick; 22–26 μm. Similar specimens occur in the Paraje Solo Formation.

Unknown 7 (Fig. 59). Oblate-spheroidal, amb circular; tricolpate, colpi straight, 15 μm long, inner margin lobate; reticulate, muri straight, smooth, 2 μm wide, lumina polygonal, 4 μm diam., becoming finer toward colpi forming a margo, reticulum deep (columellae 5 μm long); tectate-perforate, wall 6 μm thick; 45 μm.

Unknown 8 (Fig. 60). Spherical, amb circular; periporate, pores circular, 3 μm diam., widely spaced, inner margin entire; scabrate; tectate, wall 2 μm thick; 43 μm.

Unknown 9 (Fig. 61). Oblate, amb oval-triangular; tricolpate, colpi short (4 μm apex to equator), equatorially arranged, meridionally elongated, equidistant, inner margin minutely dentate; echinate, echinae short (0.5 μm), moderately dense, bases forming subreticulum; tectate, wall 1 μm thick; 40 μm.

Unknown 10 (Fig. 57). Oblate-spheroidal, amb circular; stephanocolpate, colpi 6, straight, equatorially arranged, meridionally elongated, equidistant, inner margin entire; scabrate; tectate, wall 1 μm thick; 16–21 μm.

Similar specimens occur in the Culebra Formation.

Unknown 11 (Fig. 58). Oblate-spheroidal, amb circular; tricolpate, colpi straight, tapering to acute apex, 6–8 μm long, inner margin entire to minutely dentate, equatorially arranged, meridionally elongated, equidistant; finely reticulate; tectate-perforate, wall 2 μm thick; 27 μm.

Unknown 12 (Fig. 62). Prolate, amb oval; tricolporate, colpi straight, 45 μm long, equatorially arranged, meridionally elongated, equidistant, bordered by costae colpi 4–5 μm wide, inner margin entire, pores large, oval, 5 × 16 μm, situated at midpoint of colpus, inner margin entire; reticulate; tectate-perforate, columellae relatively coarse and clearly evident in median optical section, wall 2.5–3 μm thick; 58 × 36 μm.

Unknowns 12–15 are similar to pollen of several Anacardiaceae and Euphorbiaceae but cannot be referred to any one modern genus.

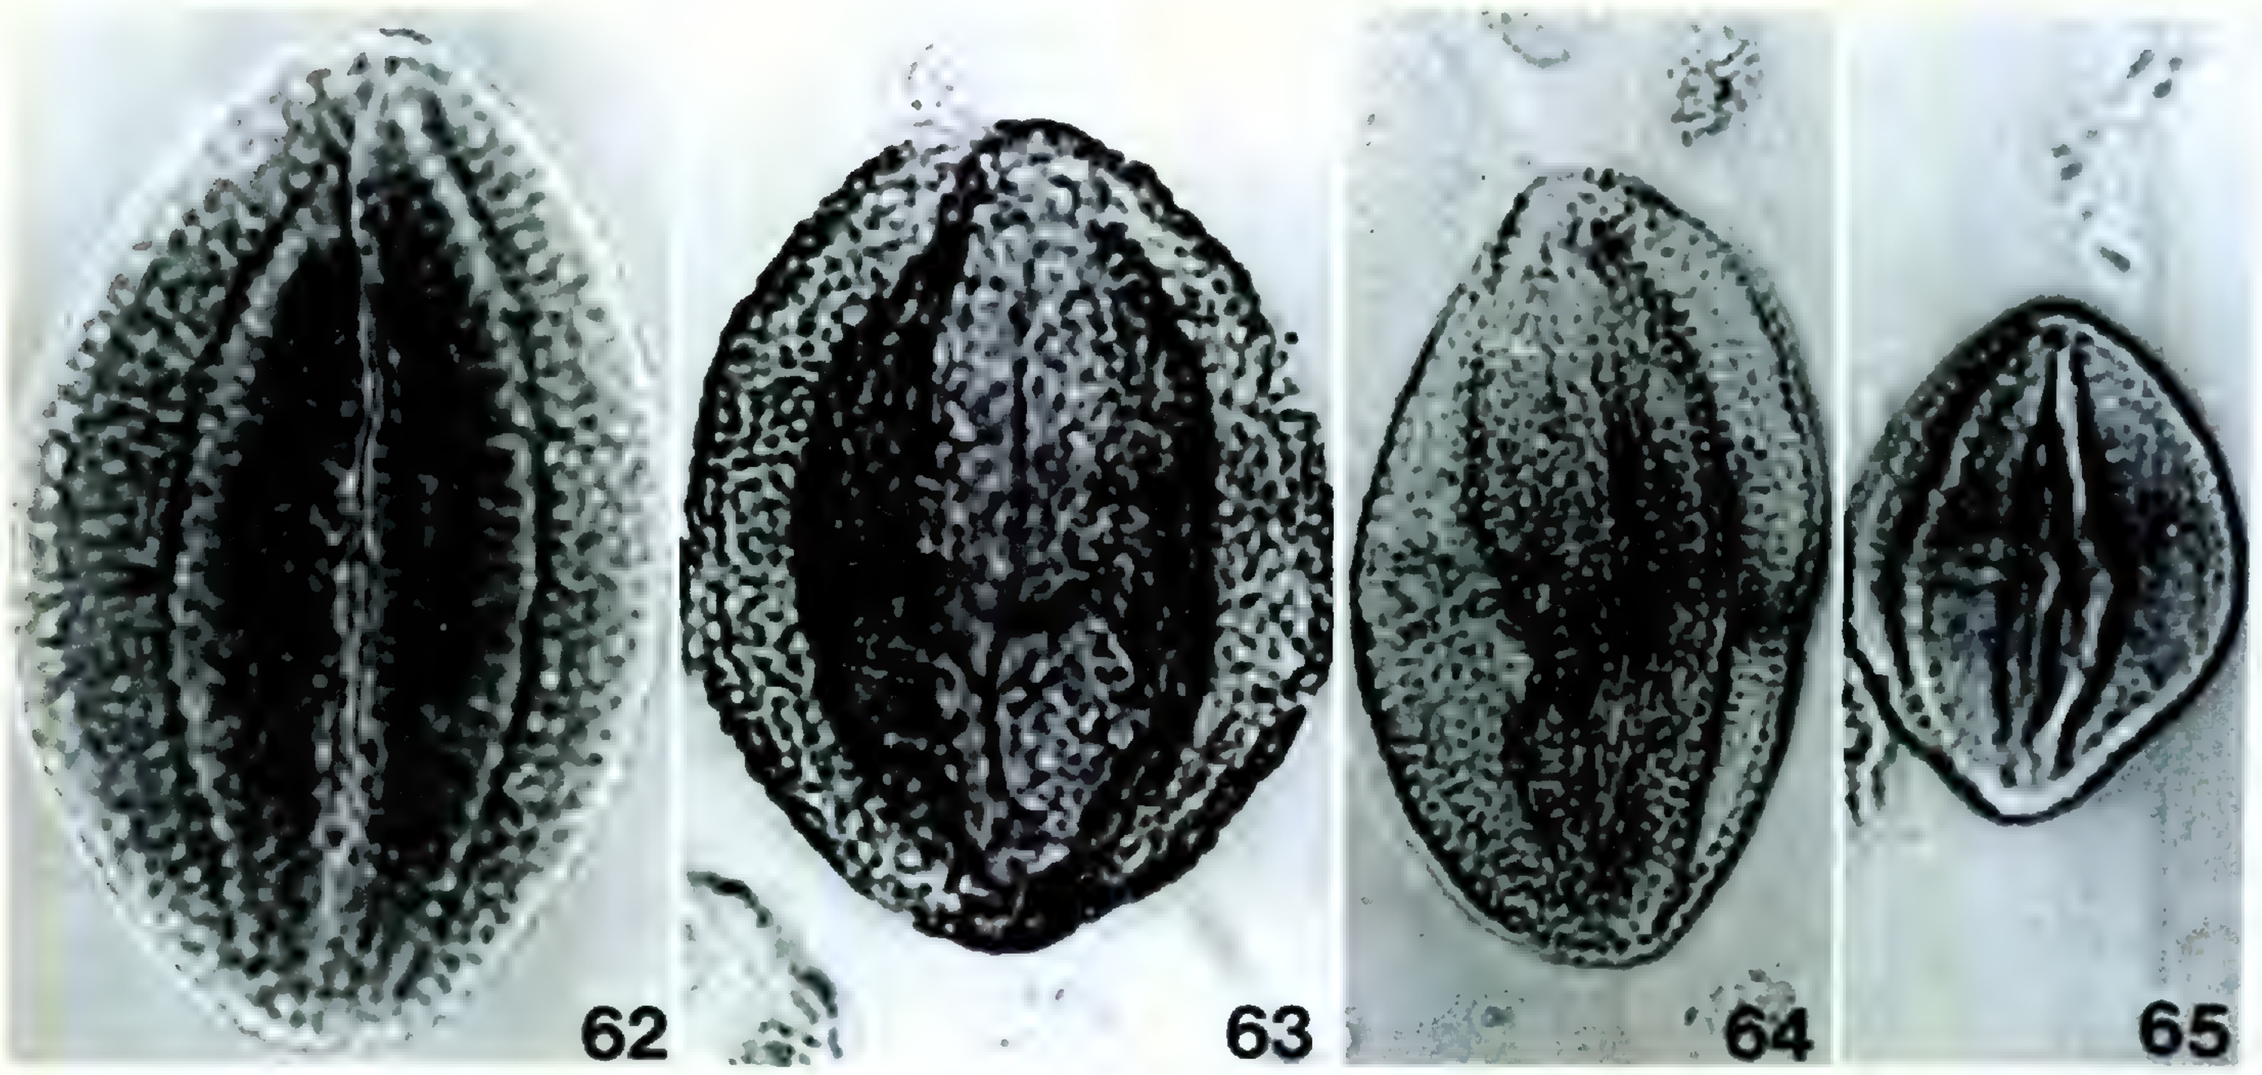
Unknown 13 (Fig. 63). This type is similar to unknown 12, but the columellae are shorter and finer; consequently, the wall is thinner (1.5–2 μm) and the reticulum finer.

Unknown 14 (Fig. 64). This type has an even thinner wall (1–1.5 μm), a finer reticulum, narrower costae colpi, and smaller and slitlike pores (2 × 4 μm).

Unknown 15 (Fig. 65). This type is similar to unknown 14 but is smaller (27–32 × 18–21 μm).

Paleocommunities and Paleoenvironments

Results of the La Boca study are of interest in demonstrating an internal consistency in paleocommunities, climates, and physiography among four fossil floras in two countries of Central America, as well as consistency with independent plate tectonic and paleotemperature data. The lower Miocene Uscari (Costa Rica), Culebra, Cucaracha, and La Boca (Panama) floras preserve elements of a mangrove swamp (*Pelliciera*, *Rhizophora*) fringing the volcanic islands constituting the isthmian region during most of the Tertiary. Freshwater marshes and swamps (palms, ferns, *Utricularia*) occupied lowland areas behind the mangrove zone. On the adjacent slopes were versions of the tropical wet, tropical moist, and premontane forests (*Lycopodium*, *Selaginella*, *Cyathea*, *Pteris*, *Ilex*, *Pseudobombax*, *Alchornea*, and *Crudia*, with *Alfaroa*/*Engelhardia* likely occupying distant, moderate highlands in the region). All available paleobotanical data are consistent in showing little evidence of dry (including savannah) habitats. Grass pollen continues to be poorly represented (maximum of 1% in one sample from the Culebra Formation; less than 0.5% in two samples from the La Boca) to absent (Uscaria, Cucaracha formations). If savannahs existed, as suggested by the



FIGURES 62–65. Fossil pollen from the La Boca Formation, Panama.—62. Unknown 12, Pan A 21-1, ESF X-14, 3.—63. Unknown 13, Pan A 16-1, ESF Q-44, 1–3.—64. Unknown 14, Pan A 16-3, ESF W-33, 4.—65. Unknown 15, Pan A 16-2, ESF W-36, 2–4.

grazing and browsing components of the Tertiary faunas, they were probably short-lived and developed locally as recovery vegetation in response to volcanic activity documented for central Panama in the form of extensive ash, tuff, and basalt deposits (see further discussion in Graham, 1988b). The affinities of the La Boca flora are clearly with Central America and areas to the north, reflecting the establishment of a land connection between Central America and South America only about 3 Ma.

The lack of any paleobotanical evidence for significant highlands is in agreement with plate tectonic models suggesting that elevation of the early volcanic islands and peninsulas gradually increased during the latter part of the Cenozoic, and that the highest elevations (3,475 m in the western mountains of Panama; 3,820 m, Cerro Chirripo, Costa Rica) are of recent origin. Altitudes up to about 1,200–1,500 m would accommodate all elements in the four lower Miocene floras known from southern Central America. No pollen was being blown, washed, or transported into the depositional basin to suggest dry vegetation or high altitudes in the Gatuncillo, Uscari, Culebra, Cucaracha, or La Boca formations of Costa Rica and Panama. Muller (1959) demonstrated that pollen from a variety of inland and upland communities is transported by rivers and deposited in coastal basins. Palynological data from Puerto Rico and southern Mexico further show that many of these habitats, represented by both wind- and insect-pollinated elements, are included in the microfossil record if such habitats exist in the region.

All taxa identified from the La Boca Formation except *Crudia* occur in the modern vegetation of Panama. Consequently the paleoenvironment must have been similar to the tropical conditions presently prevailing in coastal, lowland, and moderate-altitude habitats in southern Central America. This is consistent with paleotemperature curves (Savin, 1977; Savin & Douglas, 1985; Savin et al., 1975) that show the Uscari, Culebra, Cucaracha, and La Boca floras were deposited during a relatively warm interval just before the significant temperature drop in middle and late Miocene times.

A REVISION OF MESOAMERICAN *PSYCHOTRIA* SUBGENUS *PSYCHOTRIA* (RUBIACEAE), PART I: INTRODUCTION AND SPECIES 1–16[1]

Clement W. Hamilton[2]

Abstract

Psychotria subgenus *Psychotria* (Rubiaceae) comprises 61 species and eight varieties of understory shrubs and small trees in Mexico and Central America. The subgenus is most diverse in Panama (40 species) and Costa Rica (32 species), with a secondary center of diversity in southern Mexico (26 species) and Guatemala (26 species). Endemism is also greatest in Panama (15 species). Species-rich regions in Costa Rica and Panama are especially recommended for conservation efforts. The 61 species are grouped into eight species-groups; several groups and species complexes contain one wide-ranging species and several species with much smaller ranges. Only one species-rich group, the *P. calophylla* group, lacks a continuously wide-ranging member.

Psychotria is a pantropical and subtropical genus of mostly shrubs but also small trees, herbs, and even epiphytes. I presently estimate the number of species to be 1,650, making it the largest genus in the Rubiaceae; this includes 700 species in the Neotropics (my estimate), 250 in Africa (Petit, 1964, 1966), and 700 in Asia and Oceania (Sohmer, pers. comm.).

The present state of its infrageneric taxonomy reflects the lack of understanding of the genus as a whole; all that can be said with some certainty is that subg. *Psychotria* occurs in all three tropical regions and that each region has one or more groups distinguishable from subg. *Psychotria*. In the Neotropics, the other group is subg. *Heteropsychotria* Steyermark (1972); in Africa, it is subg. *Tetramerae* (Hiern) Petit (1964, 1966); and in Asia and Oceania, the situation is much more complex (Sohmer, 1977).

The infrageneric uncertainty extends to delimitations of *Psychotria* and related genera; the neotropical genera *Mapouria*, *Cephaëlis*, *Uragoga*, *Naletonia*, *Nonatelia*, and *Notopleura* have been variously merged with or separated from *Psychotria*. Most of these genera, if included in *Psychotria*, fall within subg. *Heteropsychotria* and are therefore not relevant here. *Mapouria*, named by Aublet in 1775, is more critical. The principal use of that generic name was by Mueller-Argoviensis (1876, 1881), who in his Rubiaceae treatment for *Flora Brasiliensis* distinguished between *Mapouria* and *Psychotria*; the former corresponded to what is properly considered *Psychotria* subg. *Psychotria*, while the latter encompassed Steyer-

[1] This paper is an amended portion of my Ph.D. dissertation at Washington University, St. Louis, Missouri, and the Missouri Botanical Garden. I thank the Division of Biological and Biomedical Sciences and the Department of Biology at Washington University and the Botany Department of the Missouri Botanical Garden for logistical and financial support during my study. Special thanks are due to A. Gentry, P. Raven, B. Schaal, and R. Foster for valuable guidance and to Karen Krager for overall assistance and many of the illustrations. Discussions on *Psychotria* with J. Dwyer, D. Lorence, J. Steyermark, and C. Taylor were very helpful. Comments on the manuscript by G. Rogers, S. Sohmer, and J. H. Kirkbride have improved it markedly. The following persons have helped me significantly at various stages of my overall study: C. & R. Hamilton, B. Tiffney, the late E. S. Barghoorn, S. J. Gould, D. Schindel, G. Congdon, P. Stevens, Puangpen Sirirugsa, W. H. Lewis, A. Templeton, G. Johnson, G. Allen, D. Neill, W. Wagner, J. Miller, P. P. Lowry, P. Hoch, W. Hahn, L. Hickey, J. Beach, W. D'Arcy, H. Stockwell, C. Augspurger, J. Fisher, D. Nicolson, and B. Hammel. I appreciate also the efforts and patience of those institutions that have provided material for study: the Harvard Herbaria (A, ECON, GH), B, CR, DUKE, ENCB, F, K, LL, MEXU, NY, SLPM, TEFH, and US.

[2] Center for Urban Horticulture, GF-15, University of Washington, Seattle, Washington 98195, U.S.A.

Ann. Missouri Bot. Gard. 76: 67–111. 1989.

mark's *Psychotria* subg. *Heteropsychotria*, including *Cephaëlis*. The discovery by Petit (1964), reaffirmed by Steyermark (1972), that the type species of *Psychotria*, *P. asiatica* L., falls well within the *Mapouria* generic concept makes that genus obsolete.

Members of *Psychotria* subg. *Psychotria* are distinguished easily from all others in the genus. Three characters serve to enable recognition of the subgenus: (1) the leaves are dry red-brown or sometimes dull green, as opposed to bright green; (2) the stipules are usually sheathing and caducous, leaving a small, usually pale ridge often with a fringe of red-brown hairs, as opposed to only slightly sheathing and conspicuously persistent; and (3) the seeds, hemispherical in cross section, have two longitudinal furrows on the flat ventral surface and usually four or five (or sometimes an irregular number of) longitudinal furrows on the rounded dorsal surface. *Psychotria* subg. *Heteropsychotria* has a variety of seed cross sections, none of which can be confused with those of subg. *Psychotria*. Additional characters of whole-plant architecture show differentiation between the two neotropical subgenera (Hamilton, 1985), as does mature fruit color, which is almost always red in subg. *Psychotria* and usually blue in subg. *Heteropsychotria*. The naturalness and monophyletic (or at least "convex"; see Meacham & Duncan, 1987) nature of subg. *Psychotria* is not in doubt.

In the Neotropics, *Psychotria* subg. *Psychotria* consists of ca. 200 species. It accounts for the vast majority of *Psychotria* species in the West Indies, just under half in Mesoamerica, and perhaps a third in South America, where subg. *Heteropsychotria* is most diverse. *Psychotria* subg. *Psychotria* in Mesoamerica, the subject of this treatment, includes 61 species, 15 of which are recently named (Hamilton, 1988), and eight varieties. I have sorted the species into eight species-groups; their recognition as sections awaits study of the subgenus throughout tropical America.

Systematic understanding of species-rich tropical taxa such as *Psychotria*, *Miconia*, *Piper*, *Bactris*, *Heliconia*, and *Anthurium* is the critical first step toward understanding geographical patterns of diversity and processes of diversification in the tropics. *Psychotria* subg. *Psychotria* appears to be a good index taxon for describing species diversity in tropical angiosperms as a whole (see Biogeography) and therefore provides a diversity data set of use to conservation planners and natural resource organizations. From an ecological and evolutionary standpoint, one hopes that results of the study of *Psychotria* can be extrapolated to other diversified tropical taxa.

Morphology and Terminology

In this section, characters and character states are explained and illustrated only as necessary in order to eliminate any ambiguity regarding their use in descriptions and discussions.

HABIT

Habit states, e.g., "shrub" versus "tree," are distinguished primarily by size, not by architecture or shape. Even 1-meter shrubs in this subgenus are usually treelike in having a main trunk and lateral branch complexes. Architecture of Panamanian species of *Psychotria* (both subgenera) has been studied (Hamilton, 1985); three basic types of branching event were found, differentiated by the number and orientation of new shoots to which the terminal node gives rise each growing season. In Type 1 branching, at the terminal node one lateral meristem gives rise to a relay axis that elongates the main axis by sympodial substitution. In Type 2 branching, two (or more) relay axes arise at the terminal node and remain equal, neither new axis assuming the same orientation as the axis that preceded it. Type 3 branching resembles Type 2 except that one of the new relay axes assumes the same orientation as the parent axis. Most species of subg. *Psychotria* shows Type 3 branching in both the vertical and lateral directions; this serves as an additional field character for recognizing members of the subgenus. Two exceptions within the subgenus—*P. limonensis* and *P. tenuifolia*—show Type 1 and Type 2 branching, confirming their taxonomic affiliation based on other characteristics (see Infrasubgeneric Relationships). Architecture has not been included in the descriptions because it has not yet been studied thoroughly for most species in the field.

STIPULES

Stipules can provide valuable information as to interspecific relationships but prove almost worthless as a source of key characters, since in this subgenus they are usually caducous, or deciduous. The two stipules on opposite sides of a node are frequently united to some degree into a sheath. As the young stem grows, mechanical pressure forces the stipules to sever their basal connections to the stem and subsequently to fall off (Fig. 1). Thus most herbarium specimens have no stipules re-

maining. The stipule scar consists of a ridge, usually pale in contrast to the stem, often with a dense fringe of minute red-brown hairs; the hairs often fall off shortly after the stipule. Exceptions to the above are found in the *costivenia* group, in which stipules are robust and not sheathing and thus are often found persisting several nodes from the terminus, and in the *calophylla* group, in which the herbaceous and suffruticose species do not grow sufficiently to force the stipules to break free.

Stipule shape and size vary considerably, with the general shape, apex, pubescence, and color differentiation providing critical distinctions between species and species groups (Fig. 2). Taxa descriptions include the stipule length along the stem followed by the maximum width.

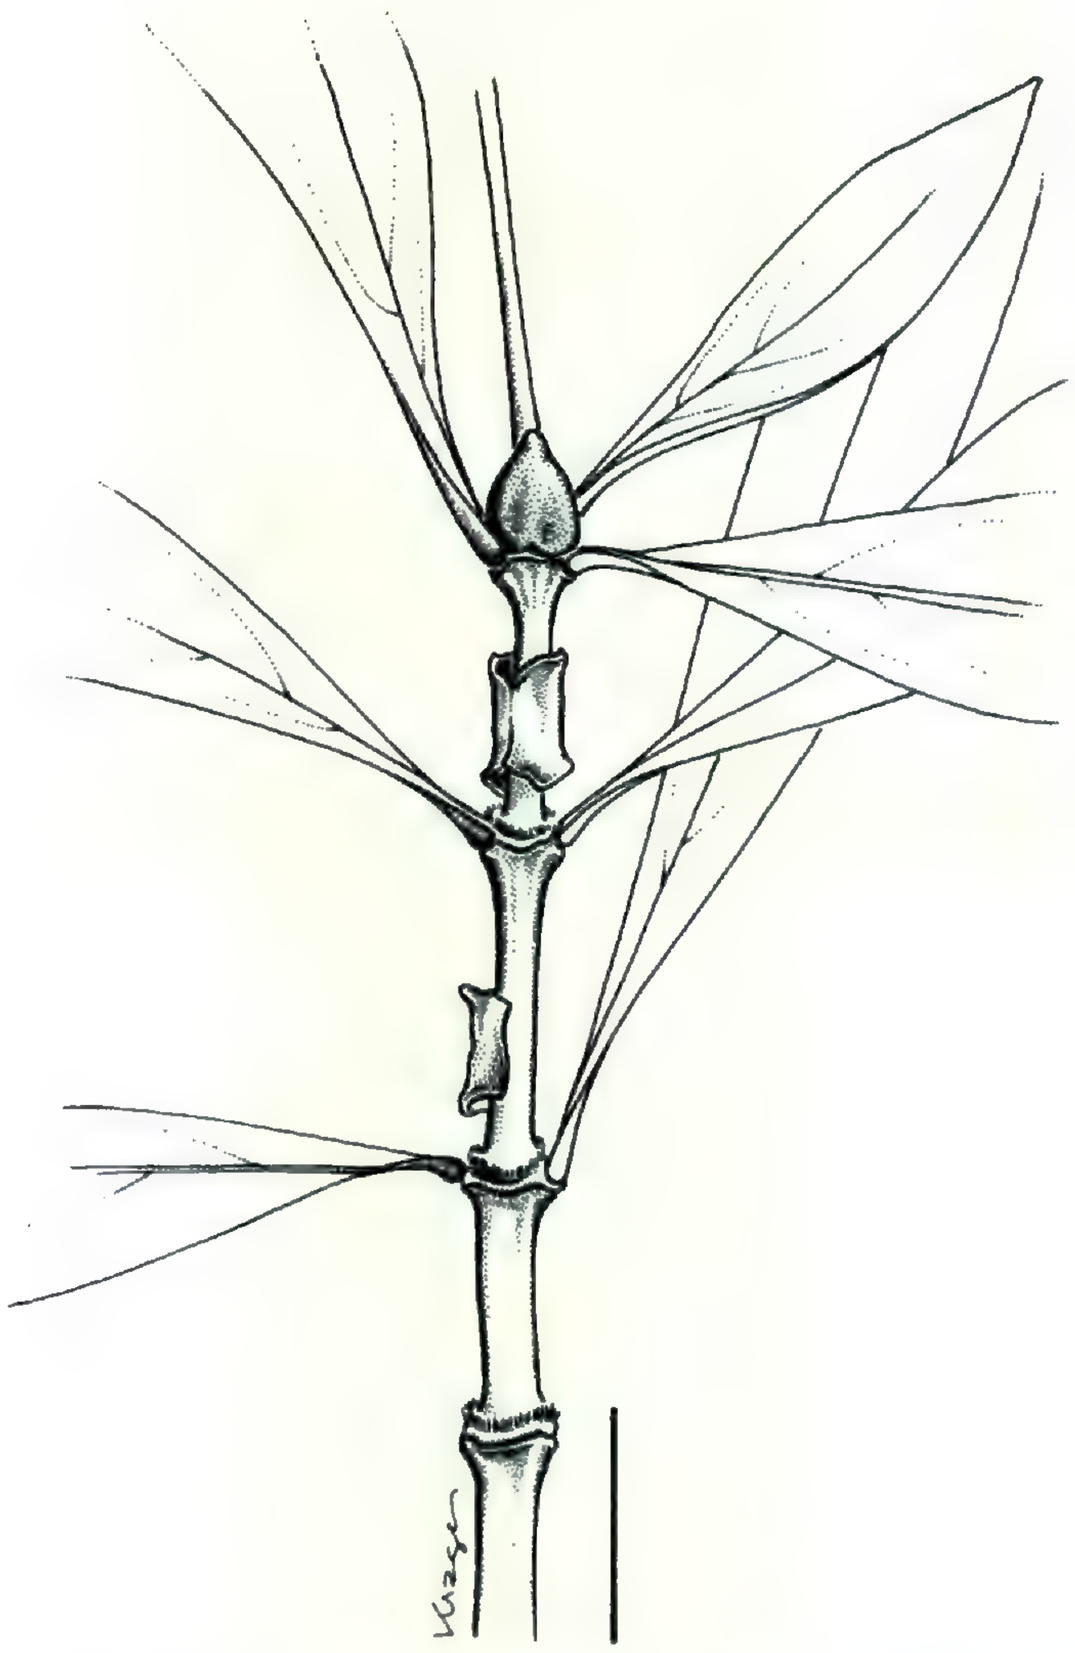

FIGURE 1. Caducous stipules being forced to fall from a branch of *Psychotria carthagenensis*. Only the terminal node has stipules firmly attached; at the node below, the sheath has broken free at the base and slid up the stem; at the next node the sheath has broken and one stipule has fallen. Note the ridge and minute fringe of hairs at the node where the stipule base has broken free. (*Knapp 4942.*) Scale bar = 1 cm.

LEAVES

Leaf characters are used extensively in this treatment in keys and as recognition characters. A single leaf, if examined critically, can suffice to identify most species in Mesoamerica. Most character states are unambiguous; descriptive terminology is from Hickey (1979). Blade measurements are the length followed by the width at the widest point. Venation character states are observed on the undersides of the leaf blades.

Secondary vein divergence is the angle formed at the junction of a secondary vein and the midvein, measured on the distal (on the leaf) side of the secondary vein. Most species have curved secondary veins, so the tangent at the base of the secondary vein was estimated and used. Angles were measured in the middle third of the leaf blade, as they often become more acute towards the base and towards the apex.

The character of secondary venation is considered to have basically three states: eucamptodromous, brochidodromous, and brochidodromous with a distinct collector vein (Fig. 3). In eucamptodromous venation, the secondary veins near the margins do not connect one to another in robust secondary arches or via a collector vein; they instead become less robust and distinct towards the margin and are often connected by a series of arches of tertiary veins (Fig. 3a). If just one connecting arch maintains the robustness of a secondary vein, the venation is said to be brochidodromous (Fig. 3b); consequently, the distinction between eucamptodromous and brochidodromous is one of degree, and many species show both states. (It may be assumed, unless stated otherwise, that the secondary arches are near the blade margin.) Much more distinct and easily differentiated—enough so to serve in the first couplet in the species-identification key—is the third state, brochidodromous with collector vein, in which there is a distinct collector vein running straight or slightly undulating near and parallel with the margin (Fig. 3c). (Note that, in keys and descriptions, the second state, "brochidodromous," should be assumed not to include a distinct collector vein unless it is otherwise stated.)

The arc shape of the secondary veins is also described, the states being: a) straight, b) constantly arcuate, and c) straight near midvein then arcuate near margin.

The axils of the secondary veins often have tufts of hairs or domatia or sometimes both. The origin and function of domatia is little understood, but the minute holes found in domatia of mature leaves suggest that early instars of some insects may inhabit the cavities (Fig. 4).

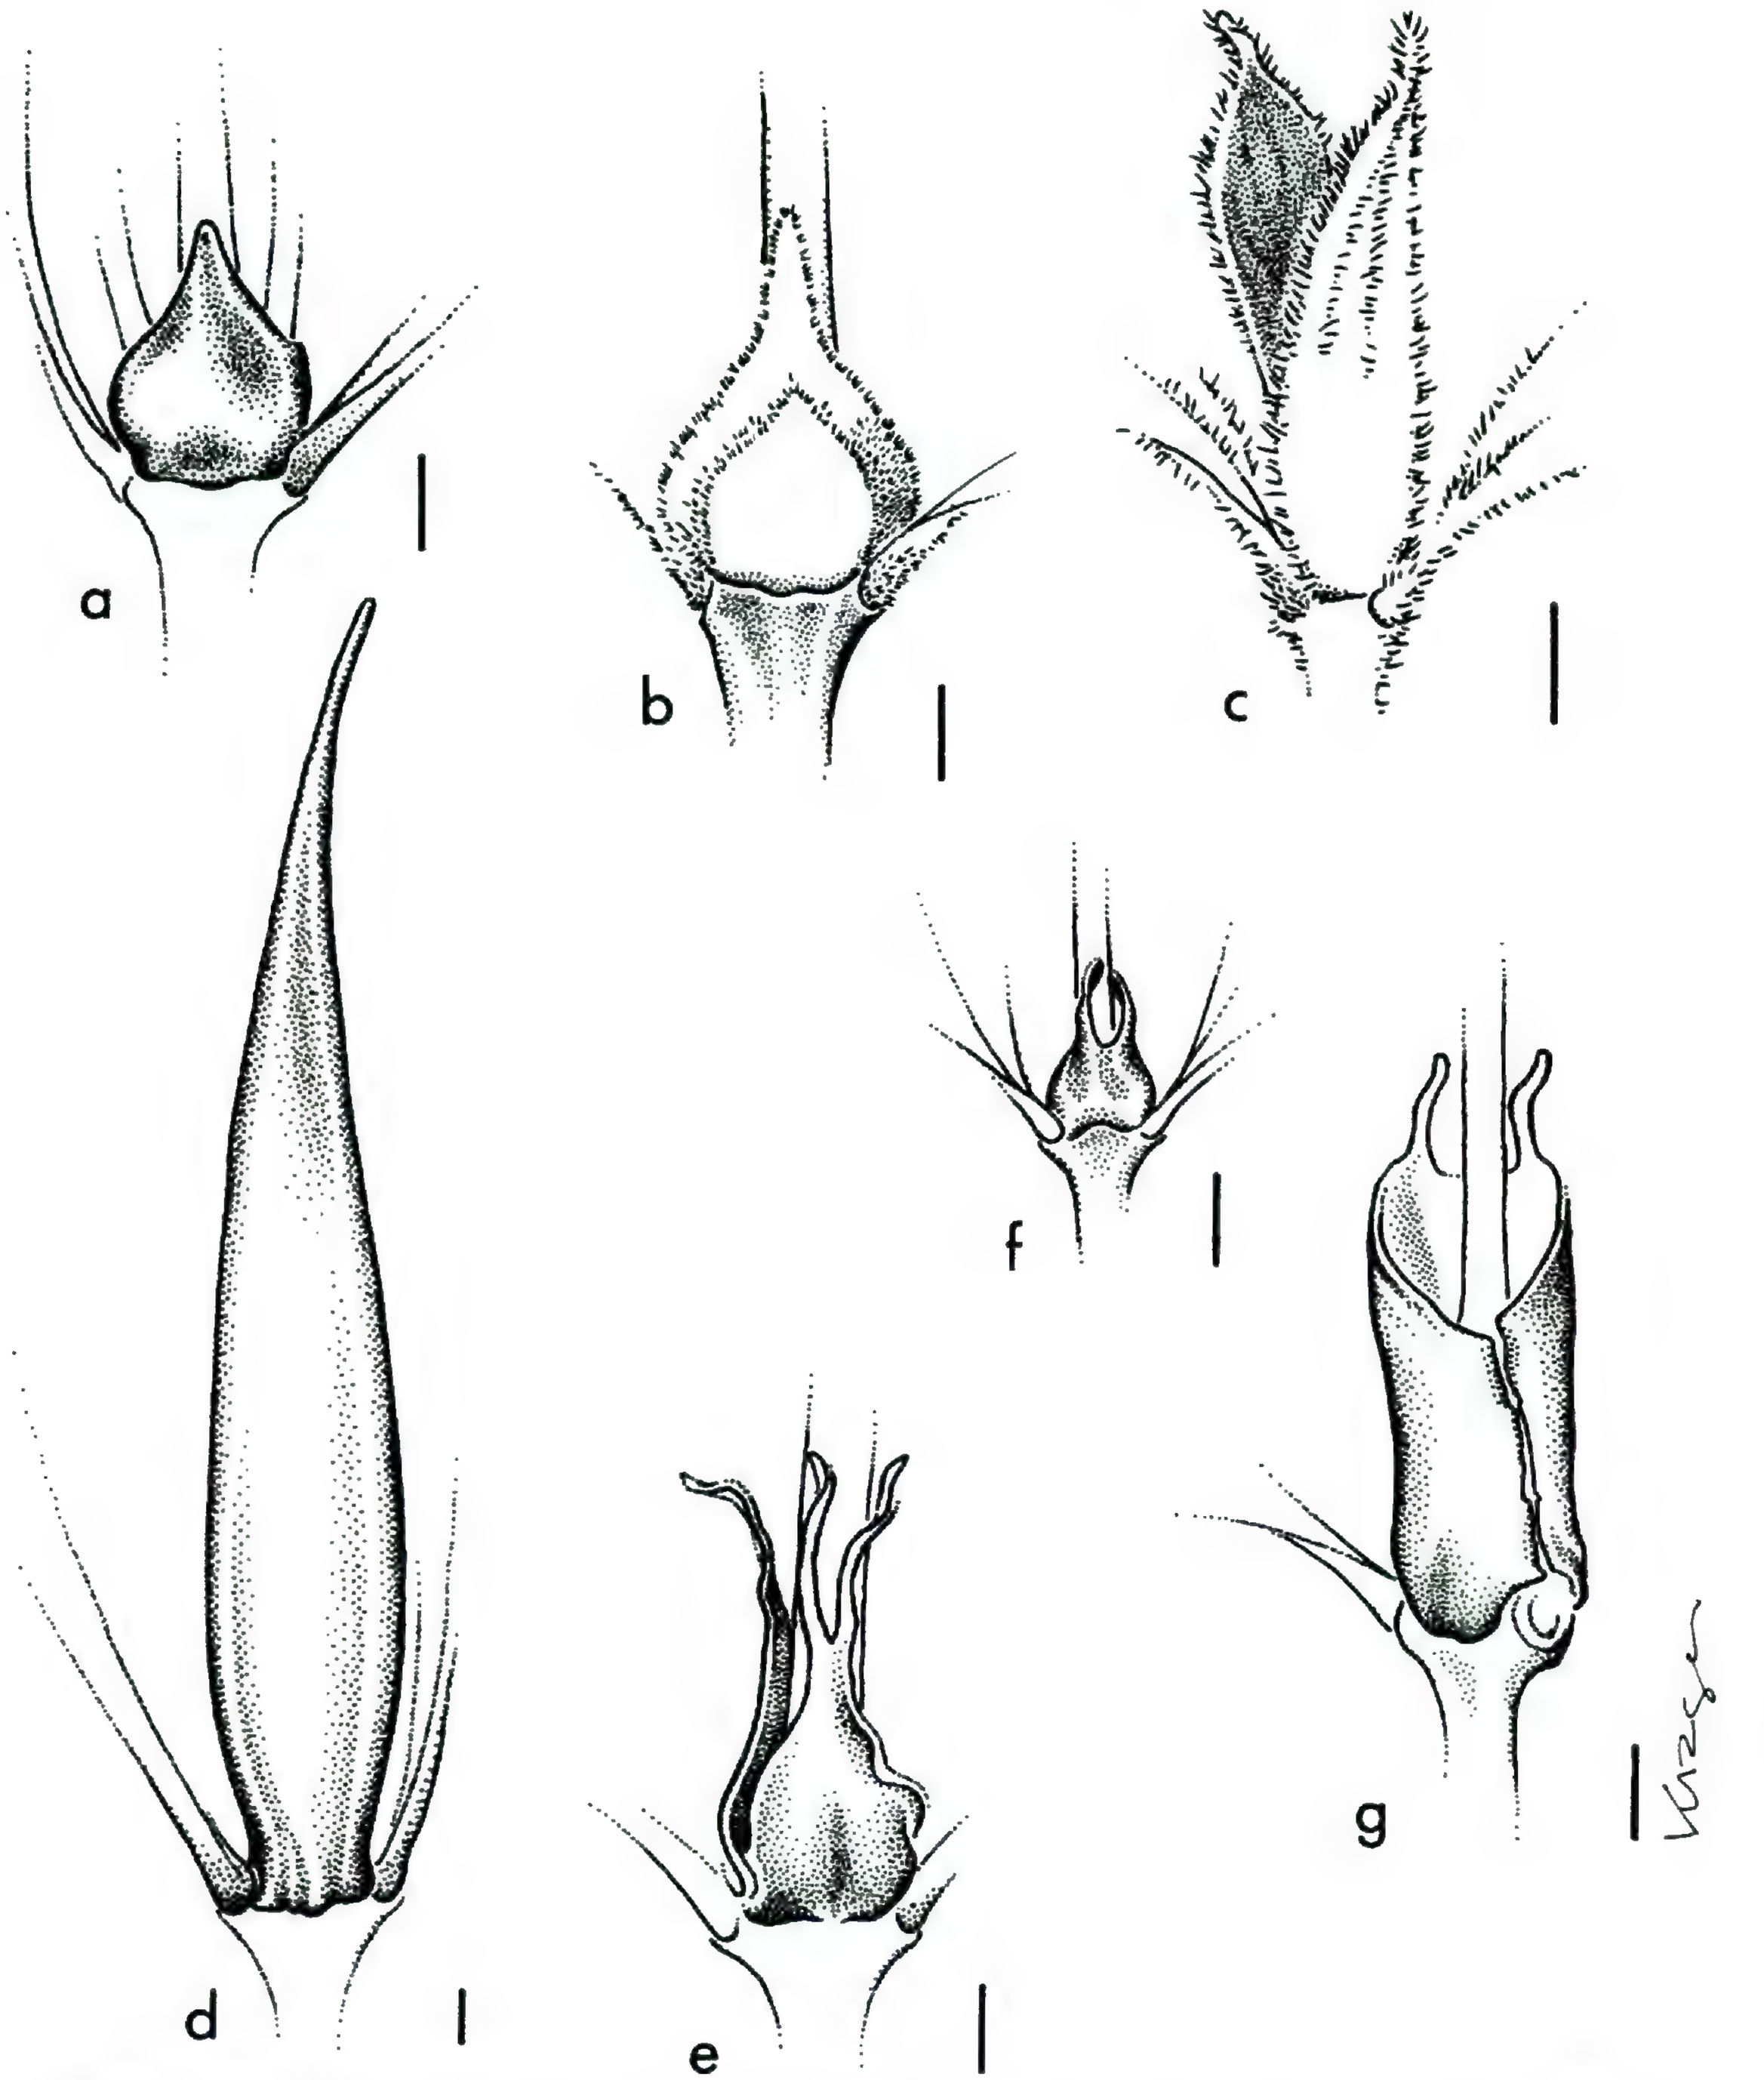

FIGURE 2. Stipule forms found in subg. *Psychotria*.—a. Sheathing, ovate, *P. carthagenensis* (*Croat 10347*).—b. Ovate, the apex cuspidate, with pale center, *P. costivenia* (*Molina & Molina 31059*).—c. Sheathing, lanceolate, *P. erythrocarpa* (*Standley 76317*).—d. Sheathing, lanceolate, *P. panamensis* (*A. Smith 1103*).—e. Ovate, the apex long-biacuminate, *P. tenuifolia* (*Hayden 174*).—f. Ovate to lanceolate, the apex biaristate, *P. orosiana* (*Knapp & Vodicka 5522*).—g. Sheathing, truncate, biaristate from apical corners, *P. psychotriifolia* (*Lewis et al. 2103*). Scale bars = 2 mm.

Tertiary veins in subg. *Psychotria* are generally either: a) orthogonal reticulate, joining each other and the secondaries, intersecting at roughly right angles, or b) percurrent, joining adjacent secondaries, making a ladderlike effect between them (Fig. 5). This distinction is often one of degree, as the major difference is that in percurrent tertiary venation the tertiaries joining the secondaries are more robust than the other reticulate veins, then considered quaternary veins. Few species, such as

P. micrantha, have strikingly percurrent tertiary venation. In several species, especially in the *costivenia* group, tertiary veins known as intersecondary veins intersect the midvein between the secondary intersections and run roughly parallel with the secondaries.

INFLORESCENCES

Inflorescences in subg. *Psychotria* consist generally of panicles of cymes, in which the cyme (dichasium) is the ultimate group of flowers and the panicle comprises the axes leading to the cymes (Fig. 6). The degree of branching of the panicle reflects the maximum branching found in the inflorescence: 2 degrees indicates that there are primary and secondary axes; 3 degrees indicates that there are primary through tertiary axes, etc. (Fig. 6a–c). Similarly, degree of branching of the cymes is also described (Fig. 6d–f). Cymes are often so contracted as to be glomerules of flowers. Bracts and bracteoles are present, though often inconspicuous, on the axes; bracts subtend branches of the panicle, and bracteoles subtend the cymes.

Inflorescence organization provides many of the most useful characters and so is described in great detail (Fig. 7). Secondary axes are borne in ranks along the main axis. The main axis itself is measured; the distance between the base of the main axis and the point of insertion of the basal (first) rank of secondary axes is the peduncle (its length included in the measure of the main axis). Secondary axes are usually two or four per rank; often when there are two or more pairs of axes per rank, the pairs are differentiated into a longer and a shorter pair (Fig. 7a). Often a specified node can have either one or two pairs of axes; measurements of a single pair are included under "the longer pair," while measurements of the "shorter pair" are relevant only when there are two pairs of axes. Sometimes secondary axes are reduced so that a cyme or flower cluster appears sessile on the main axis (Fig. 7b, k). The angle of divergence of the secondary axes (measured as is that of secondary veins) can also provide valuable information: species in the *graciliflora* group often have ca. 90° angles of divergence (Fig. 7h), and *P. stockwellii* shows obtuse angles of divergence (Fig. 7i), in striking contrast to the acute angles characterizing most species.

FLOWERS

The most interesting feature of the flowers of *Psychotria*, as is the case for much of Rubiaceae,

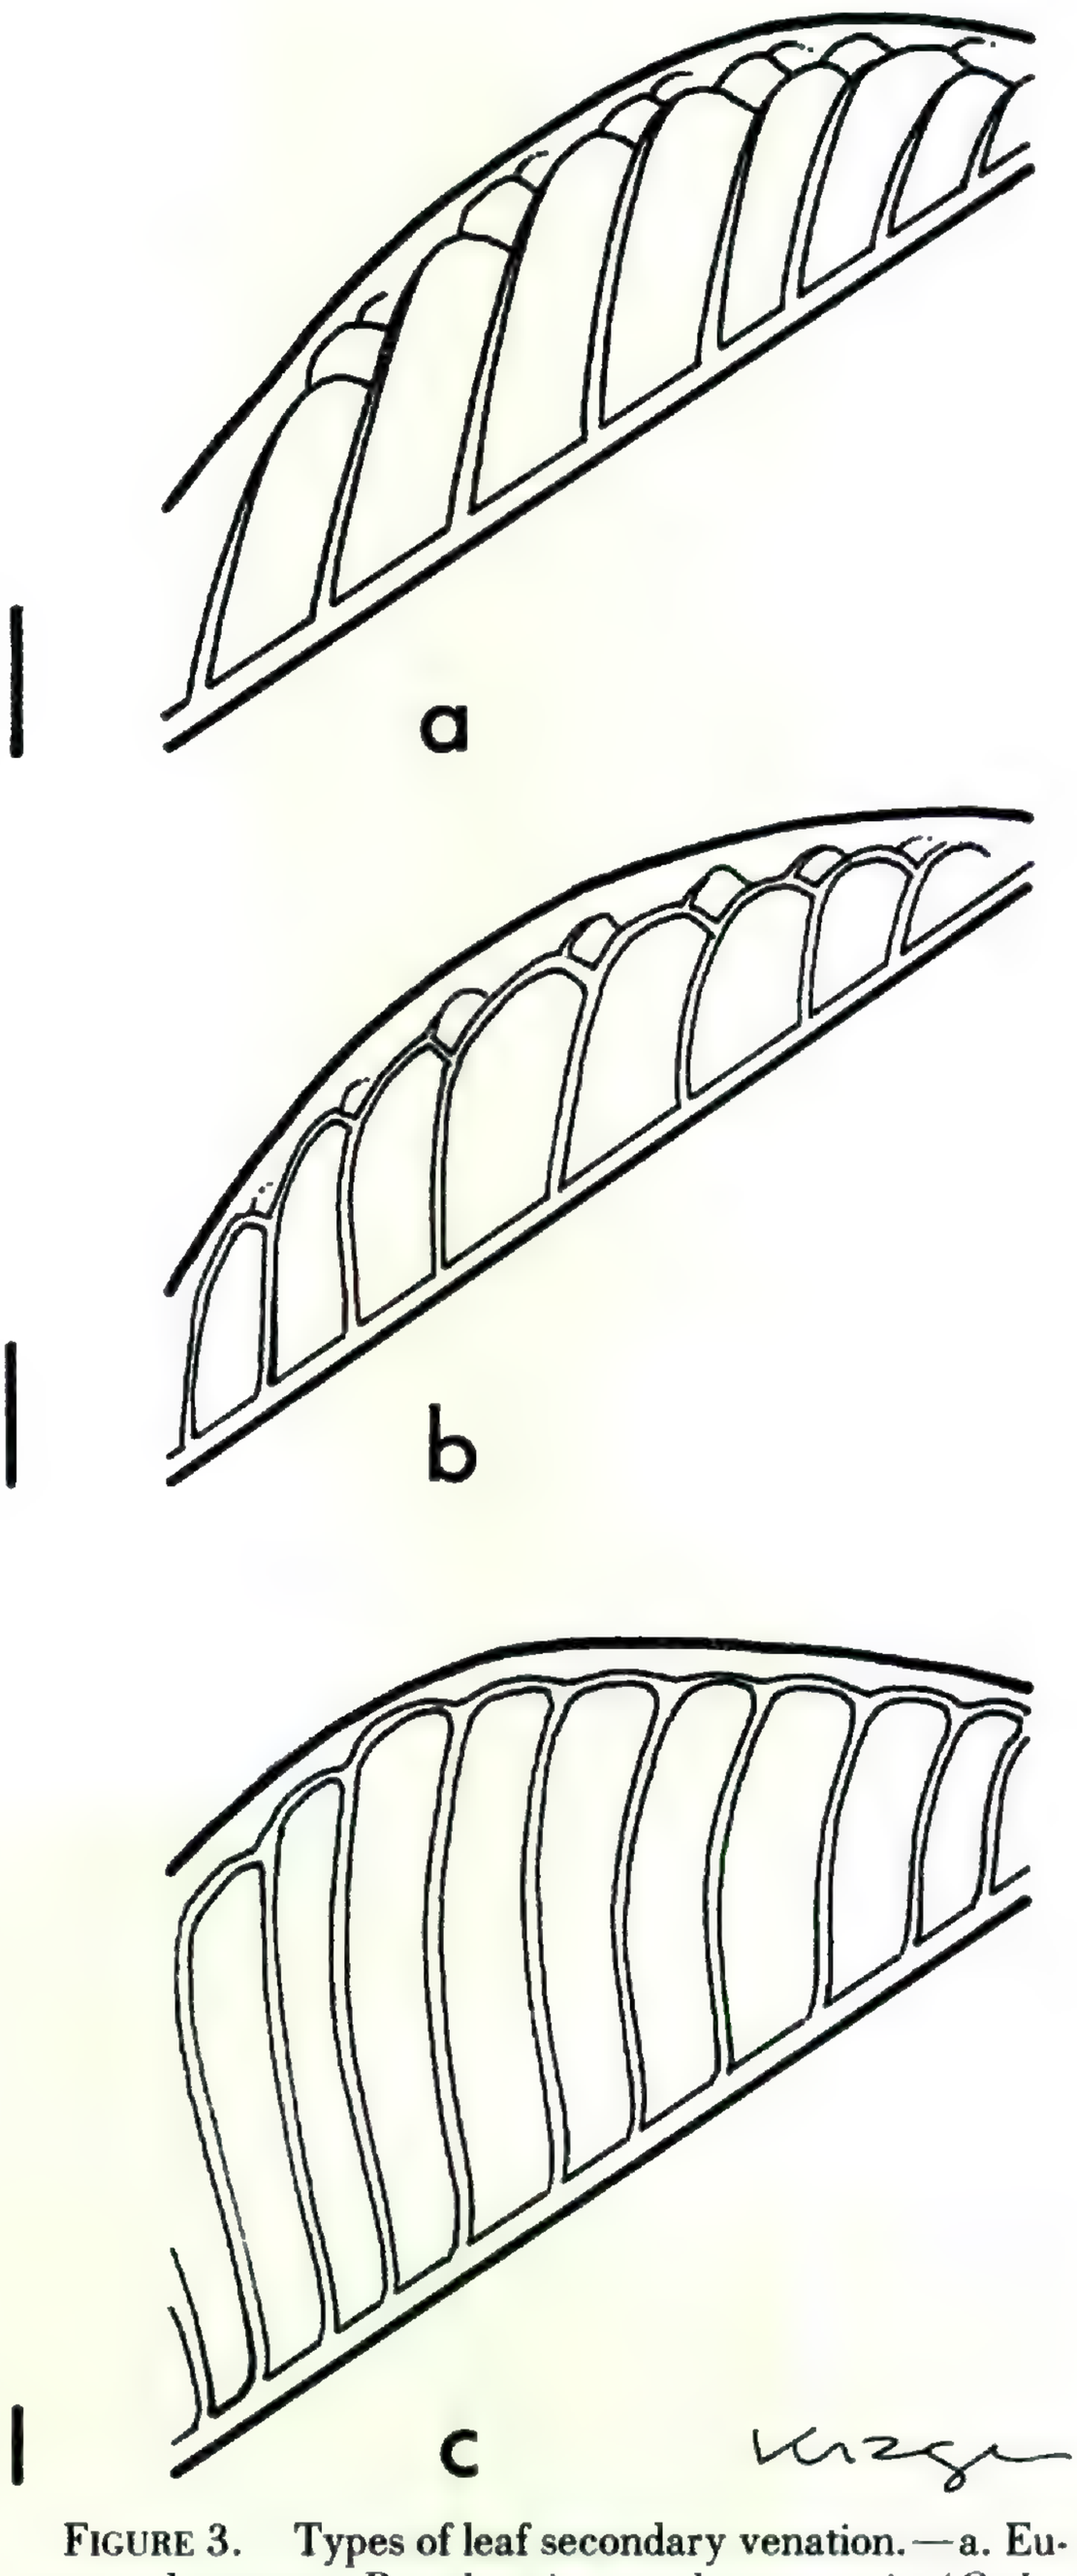

FIGURE 3. Types of leaf secondary venation.—a. Eucamptodromous, *Psychotria carthagenensis* (*Opler 1683*).—b. Brochidodromous, *P. horizontalis* (*Spellman & Newey 1670*).—c. Brochidodromous with collector vein, *P. calophylla* (*Tyson et al. 4556*). Scale bars = 1 cm.

is distyly: within a species many individual plants have flowers with exserted style and inserted stamens ("pin" or "long-style" morph; Fig. 8a–c), and the others have flowers with exserted stamens and inserted style ("thrum" or "short-style" morph; Fig. 8d–f). This is part of an incompatibility system by which pin pollen can fertilize only thrum ovules

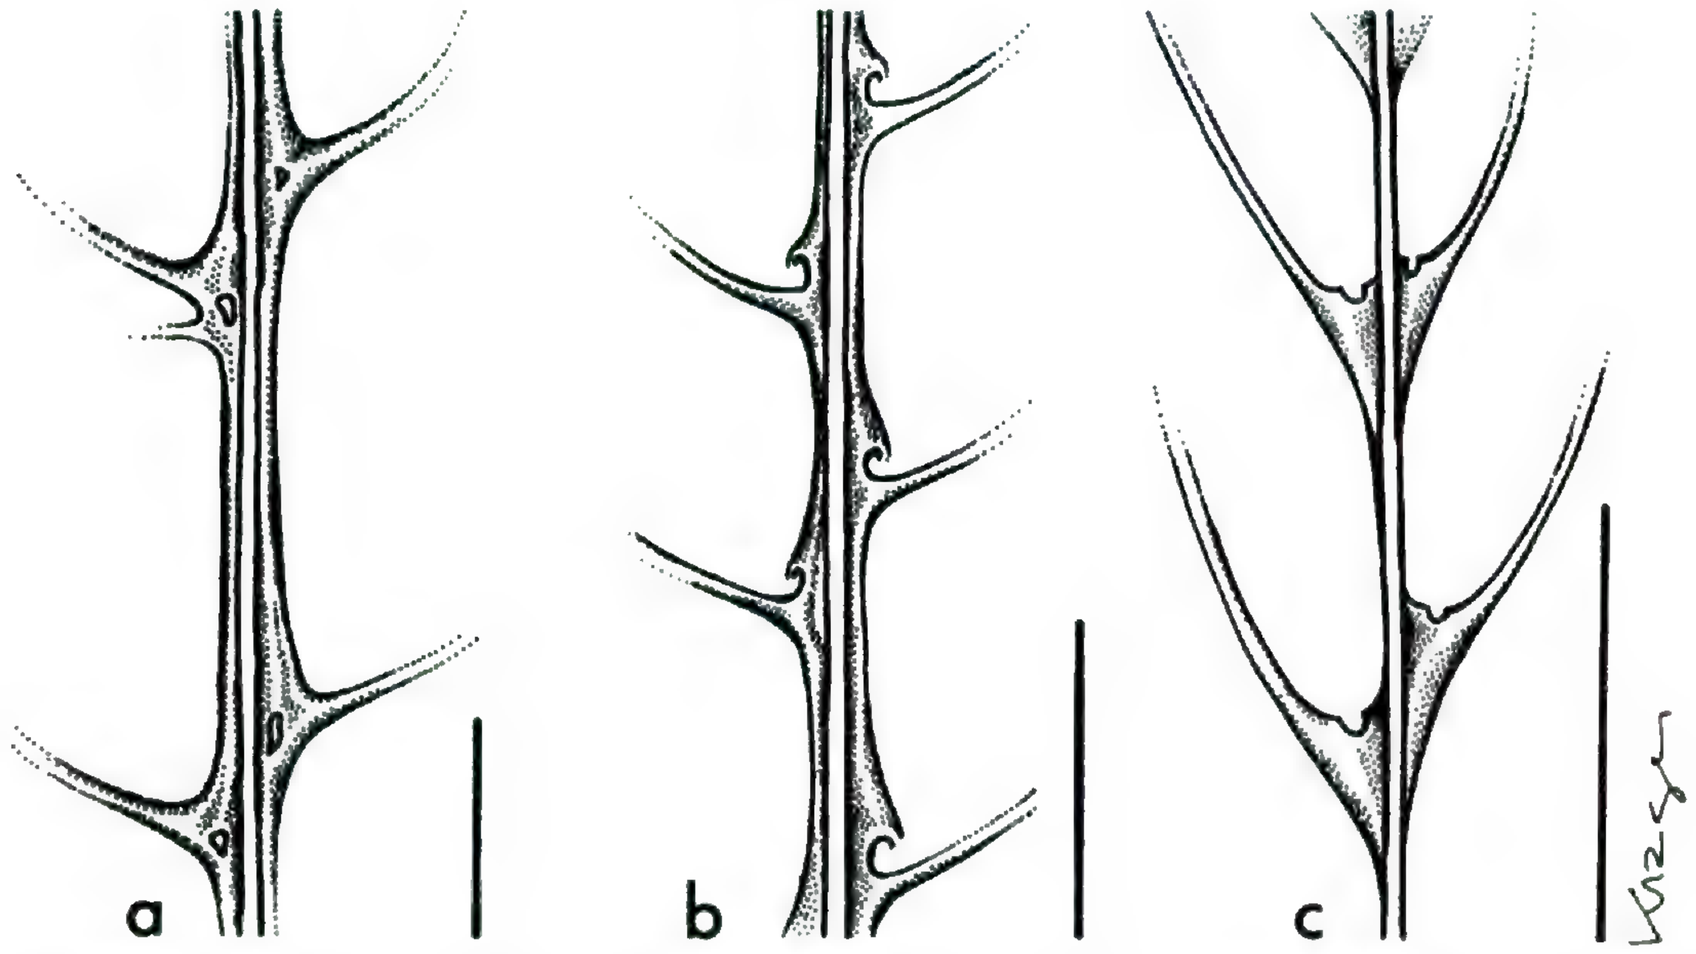

FIGURE 4. Domatia in axils of secondary veins.—a. *Psychotria remota* (*Hartshorn 1444*).—b. *P. marginata* (*Correa & Dressler 1015*).—c. *P. viridis* (*Duke 10230*). Scale bars = 1 cm.

and vice versa, i.e., intramorph incompatibility (Darwin, 1877; Ganders, 1979). From the standpoint of descriptive morphology, it means that flowers of both morphs must be described, with their different filament and style lengths.

Of the 66 taxa in Mesoamerican *Psychotria* subg. *Psychotria*, 40 appear normally distylous, as judged from morphology alone. Five are "long-homostylous," i.e., having only one flower morph, in which stamens and style are both exserted. Five other taxa appear to have only one of the two distylous morphs: two are "pin-monomorphic" and three are "thrum-monomorphic." No cases of dioecy are evident from flower morphology alone. (The remaining 16 taxa cannot be assigned a category because too few flowering specimens were available for analysis.) Nondistylous states of breeding biology are not concentrated in any particular species group (see Infrageneric Relationships) and are

Scale bars = 1 cm.

therefore hypothesized to have evolved independently of one another from primitive distyly (Hamilton, in press).

Measurements of corolla tubes and lobes are length followed by maximum width (diameter in the case of the tubes).

Stamen filaments are invariably fused to the corolla tube; their point of separation from the tube is often difficult to ascertain, however, so I have measured the filaments from the base of the corolla tube. Using this measurement and that of style length, one can determine the spatial separation between anthers and stigma. The filaments connect to the anthers usually halfway up the introrse anther thecae.

FRUIT

All fruit measurements are of dried herbarium material and so will differ from those of fresh fruits with fleshy exterior. Fruit shape is a useful character, straightforwardly described. Persistent calyces can also be valuable; Figure 9 indicates the variation within the subgenus and how the relative lengths of calyx tube and lobes can affect the aspect of the fruit.

The two seeds, often called pyrenes (cf. Steyermark, 1972; Dwyer, 1980), are hemispherical in cross section and thus have two surfaces to consider: the rounded, outside "dorsal" surface and the flat, inner "ventral" surface. Longitudinal furrows run along both surfaces, and their number, depth, and regularity serve as important characters. Figure 10 illustrates the variation within the subgenus, with *P. carthagenensis* (Fig. 10a) representing the most common type of cross section. The depth of the furrows on the dorsal surface affects the external appearance of the whole dried fruit: *P. remota* (Fig. 10f) fruit appears deeply ribbed, while that of *P. grandis* (Fig. 10i), with its many shallow irregular furrows, appears smooth.

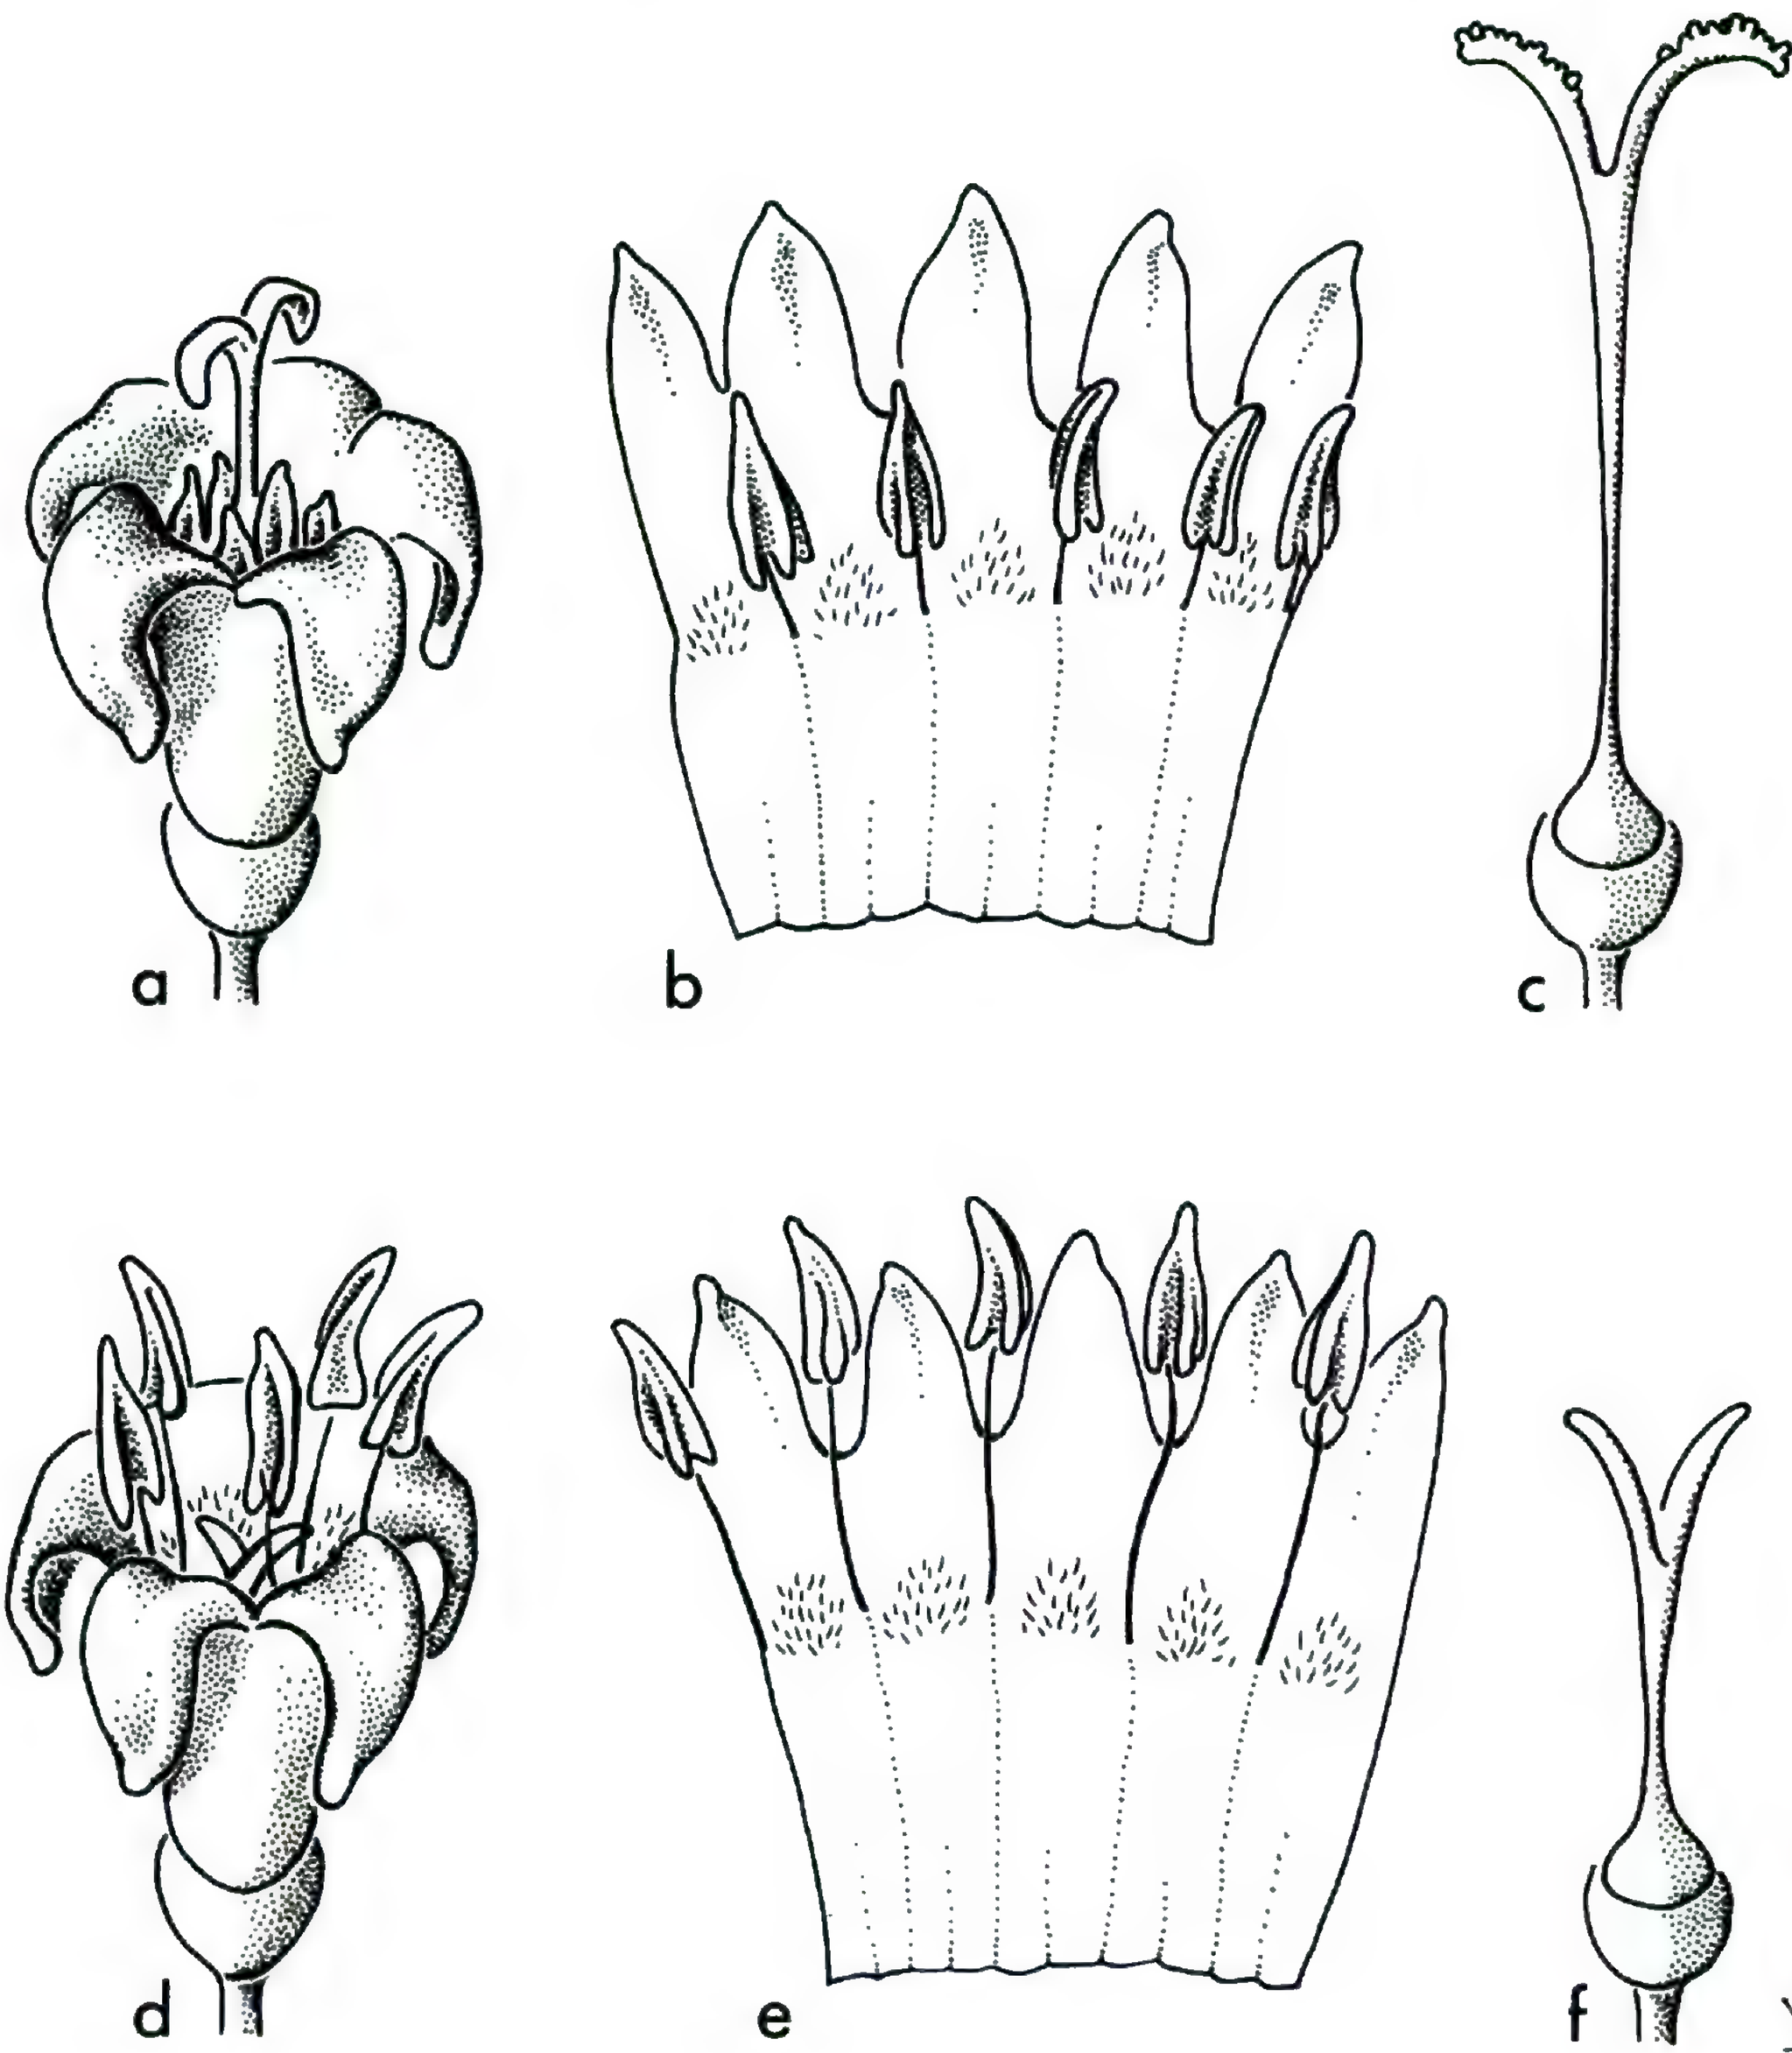

FIGURE 8. Long-style (pin) and short-style (thrum) flower morphs of *Psychotria marginata*.—a–c. Long-style morph (*R. Foster 1696*).—d–f. Short-style morph (*Antonio 2305*). a, d, whole flowers; b, e, dissected corollas; c, f, pistils. Scale bar = 1 mm.

BIOGEOGRAPHY

For purposes of biogeographical analysis I have divided Mesoamerica into nine regions (Fig. 11). The most species and most endemic species of subg. *Psychotria* are found in Panama (40 species; 15 endemics); both diversity and endemism drop somewhat in Costa Rica (32/7). There is a diversity "trough" in middle Mesoamerica (Honduras, El Salvador, and Nicaragua), with absolutely no endemism. A secondary center of diversity includes region 3 (eastern Veracruz, Tabasco, Oaxaca, and Chiapas in Mexico) and region 5 (Guatemala and Belize), both areas having 26 species and a few endemics. Other parts of Mexico have only range extensions of some species found in regions 3 and 5.

The striking pattern of species diversity of subg. *Psychotria* within Mesoamerica appears to represent general diversity patterns of moist- and wet-forest vascular plants (Fig. 11). This pattern—most diversity and endemism in Costa Rica and Panama, a secondary center in southern Mexico

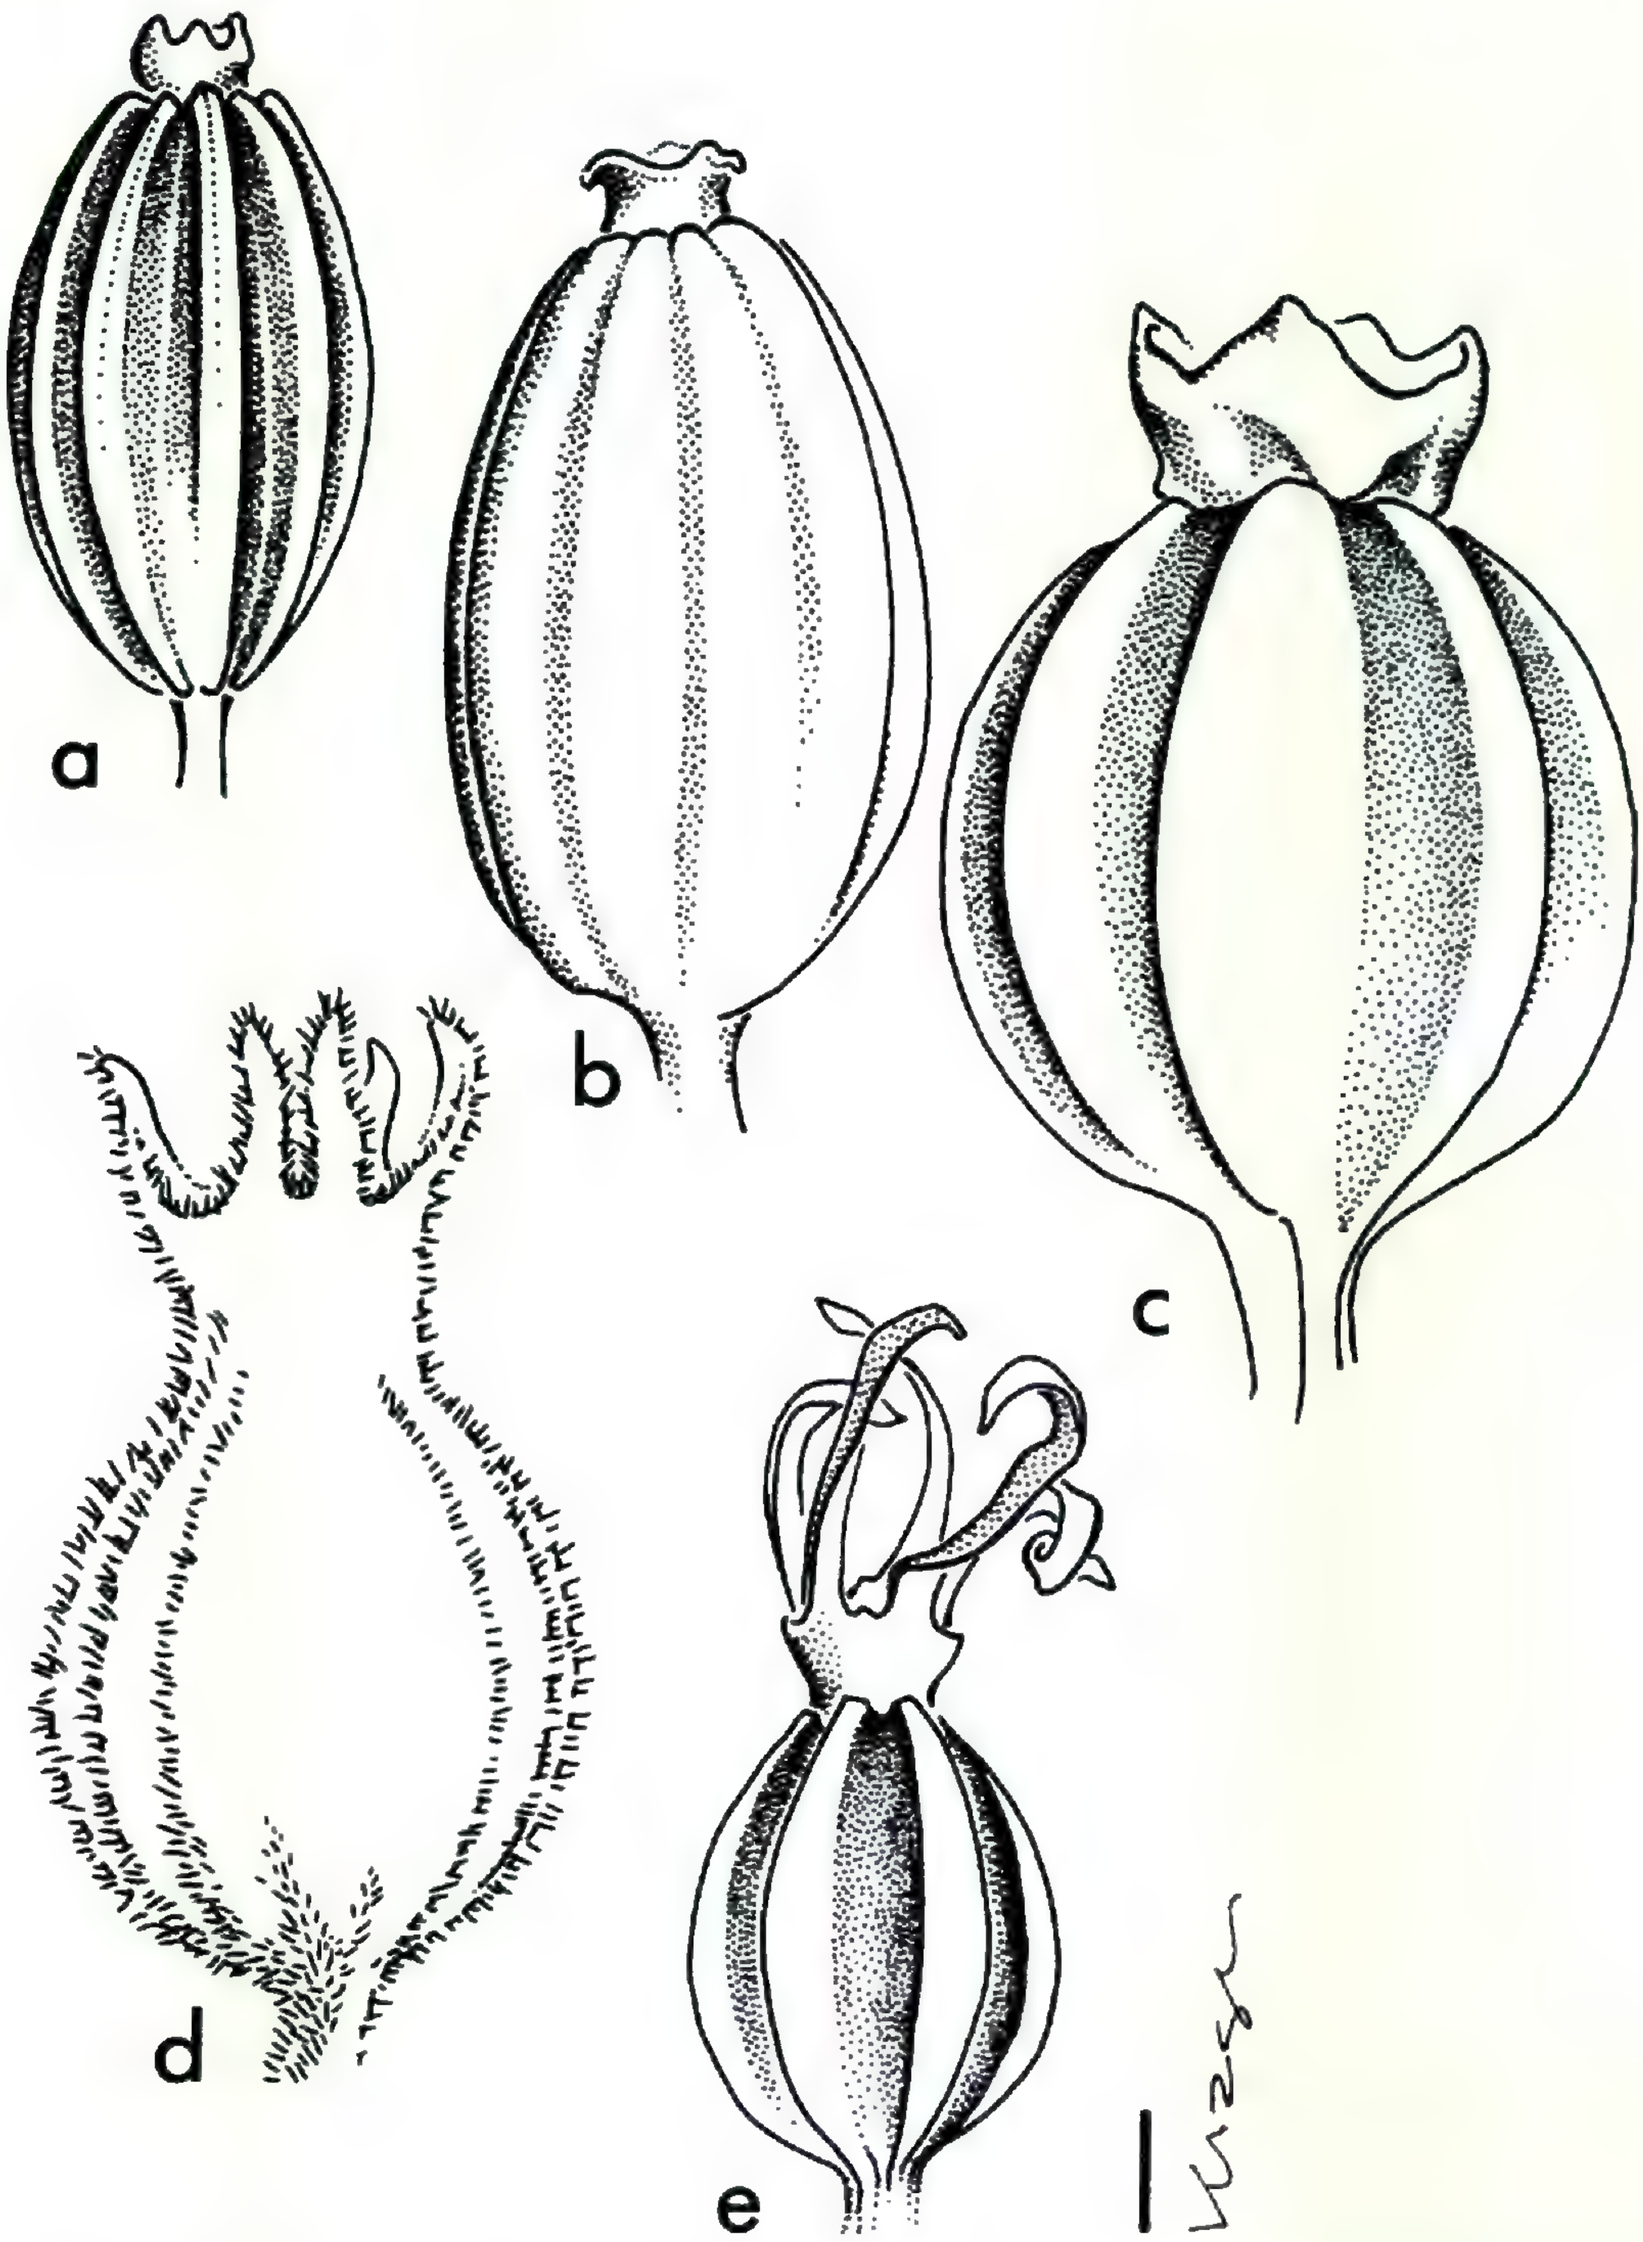

FIGURE 9. Dried fruit with persistent calyces.—a. *Psychotria carthagenensis* (*Standley & Valerio 44926*).—b. *P. papantlensis* (*Contreras 7958*).—c. *P. cocosensis* (*Pittier 12375*).—d. *P. jinotegensis* (*Lauvert & Barkley 39552*).—e. *P. horizontalis* (*Witherspoon & Witherspoon 8693*). Scale bar = 1 mm.

(region 3) and Guatemala, and little between—is found in other recently monographed species-rich taxa of moist- and wet-forest plants (Table 1). The *Anthurium* pattern (tabulated from Croat, 1983, 1986) is an amplified version of that of *P.* subg. *Psychotria*, with nearly seven times as many species in Panama as in Nicaragua. *Cordia* sect. *Micranthae* (Miller, 1985) and *Monochaetum* (Almeda, 1978), with somewhat smaller data sets, also reflect the general trend. *Cavendishia* (Luteyn, 1983) and *Heliconia* with pendent inflorescences (Kress, 1984) also have greatest diversity in Panama and Costa Rica but show no secondary center in Mexico and Guatemala.

All these data sets suggest strongly that the diversity pattern of subg. *Psychotria* represents that of many species-rich taxa and may therefore be of value as an index of regional diversity for tropical flowering plants. The primary value of this would be in pinpointing areas to which we should devote conservation effort in order to preserve the maximum diversity of life. Figure 12, a map of species numbers per one-degree square, reveals great differences in diversity that cannot be dismissed as collecting artifact. It is also noteworthy that all nine squares with significant endemism are in Costa Rica and Panama (Table 2).

Areas in Costa Rica and Panama with particularly high endemism are largely identical to those noted by Croat (1983, 1986) for *Anthurium*, most-

ly 1,000–2,000 m elevation along the Continental Divide plus isolated hilly areas. Costa Rican endemics *P. chitariana*, *P. monteverdensis*, and *P. sylvivaga* fit this pattern, as does *P. stockwellii*, which extends from Alajuela to western Chiriquí, Panama. The Divide in western Panama has several narrow-ranging species: *P. boquetensis*, *P. hornitensis*, *P. hammelii*, *P. insueta*, and *P. cascajalensis*. Just east of the Canal, the Cerro Azul–Cerro Jefe region has three endemics: *P. liesneri*,

[4] Has been collected in only two or three additional squares.

P. olgae, and *P. pacorensis*. Mountains near the Colombian border support three more: *P. philacra* (Cerro Tacarcuna), *P. rosulatifolia* (Cerro Malí and Cerro Pirre), and *P. insignis* (south of Puerto Obaldía). Three narrow-ranging species, *P. laselvensis*, *P. sixaolensis*, and *P. fendleri*, are found in areas of Caribbean lowlands, which have not been botanized thoroughly. It is beyond the scope of this treatment to speculate on the causes of these patterns—e.g., absolute rainfall, topographical heterogeneity, geological disturbance—but the pattern suggests that Costa Rica and Panama deserve the lion's share of *in situ* conservation focus in Mesoamerica.

The biogeographies of species complexes, within groups, display consistent patterns that suggest hypotheses as to the course of evolution within the complexes (see Infrageneric Relationships). Many species complexes are comprised of one widespread species, for which the complex is named, plus one or more species with much narrower ranges: the *Psychotria quinqueradiata* complex (two species), the *P. micrantha* complex (two species), the *P. horizontalis* complex (two species), the *P. costivenia* complex (seven species), the *P. graciliflora* complex (seven species), the *P. chagrensis* complex (two species), the *P. nervosa* complex (four species), the *P. chiriquina* complex (three species), and the *P. panamensis* complex (six species; see distribution maps in the introductions to each species group in the Systematic Treatment). Seven widespread species, such as *P. carthagenensis* and *P.*

FIGURE 12. Numbers of species of *Psychotria* subg. *Psychotria* per one-degree square. Squares of high endemism (see Table 2) are shaded.

marginata, are not obviously similar to any narrow-ranging species. Group 8, the *calophylla* group, defies even tentative analysis of affinities: most species are narrow endemics in Costa Rica and Panama, with only *P. calophylla* and *P. psychotriifolia* having somewhat wider ranges. The predominant pattern of one widespread plus one or more narrow-ranging species accounts for 35 of the 61 species and suggests that in each complex the widespread species may be ancestral to those with narrow ranges. Careful phylogenetic analysis of the subgenus throughout the Neotropics is necessary to evaluate this hypothesis.

Each species and variety account in the Systematic Treatment includes a characterization of range in terms of habitat and climate. The habitat classification used is that of Holdridge (1967), particularly from life zone maps of Costa Rica (Tosi, 1969) and Panama (Anonymous, 1970). The ranges of many Mexican species are characterized according to a vegetation map of that country (Flores Mata et al., 1971). Climate types are those of Walter et al. (1960), discussed by Walter (1973); the particular climate types referred to herein are six: I equatorial, I(X) equatorial-mountainous, I(II) equatorial-tropical, II(I) tropical-equatorial, II tropical, and II(X) tropical-mountainous. Equatorial and equatorial-mountainous climates may show some seasonality of rainfall, but the ratio of precipitation (in mm) to temperature (in degrees centigrade) never drops below 2:1 in any month. In an equatorial-tropical climate, there is a mild dry season in which the ratio drops slightly below 2:1 for one or two months, usually around March. In a tropical-equatorial climate, the dry season is more extreme, lasting up to four months at the beginning of the year. The dry season in a tropical or tropical-mountainous climate usually lasts November through April, some of those months often having absolutely no precipitation.

Infrasubgeneric Relationships

Formal taxonomic recognition of sections awaits understanding of the subgenus throughout the Neotropics. For the time being, I have divided the 61 Central American species into eight groups comparable to sections. In several cases I refer to species complexes, which are sets of morphologically very similar species within a group.

The following key to species groups indicates major differences among the groups and is primarily didactic; it utilizes characters, such as stipules, that are useful at the species-group level but less so for species identification, e.g., because stipules are caducous and fruits are often not present. For species identification, one should use the key to species in the Systematic Treatment; it relies

largely on leaf and inflorescence characters, which are most consistently evident.

Following the key are brief synopses of the eight species groups, including lists of species, geographic patterns, and noteworthy character states not in the key. More extensive descriptions, with distinctive character states italicized, plus discussions of species relationships, biogeography, and breeding biology will be found at the beginning of each group in the systematic treatment.

Key to Species Groups

1a. Inflorescence axes almost always 4 (or 6) per rank in at least one rank, in usually 2 (or 3) unequal pairs 2
1b. Inflorescence axes generally 2 per rank or, if 4 or clustered, equal in length 3
2a. Leaves drying generally green-brown to red-brown to red-gray ..... Group 1—*carthagenensis* group
2b. Leaves drying generally dull green to yellow-green ..... Group 2—*costivenia* group
3a. Leaf secondary venation eucamptodromous to brochidodromous without a collector vein 4
3b. Leaf secondary venation usually brochidodromous with a collector vein near the margin or, if eucamptodromous, the corolla lobes with apical extensions and/or the inflorescence bracts enlarged 7
4a. Inflorescences generally pedunculate, the secondary axes diverging usually at right angles 5
4b. Inflorescences usually lacking peduncle, the secondary axes generally diverging at acute (obtuse in *P. stockwellii*) angles 6
5a. Leaves drying usually gray-green to green-black or red-black; inflorescence secondary axes elongated in all ranks; seed dorsal surface with 3–5 deep furrows, sometimes plus several irregular longitudinal furrows ..... Group 3—*graciliflora* group
5b. Leaves drying glossy red-brown; inflorescence secondary axes significantly elongated only in the first rank; seed dorsal surface with 3 deep longitudinal furrows ..... Group 4—*remota* group
6a. Plants often ferrugineous-pubescent or tomentose; persistent calyx often conspicuous, 2–5 mm long; seed dorsal surface usually with 4–5 regular longitudinal furrows ..... Group 5—*nervosa* group
6b. Plants not ferrugineous-pubescent or tomentose; persistent calyx inconspicuous or a small beak or rarely a coriaceous cup; seed dorsal surface with 4–10 irregular longitudinal furrows ..... Group 6—*panamensis* group
7a. Inflorescences umbelliform panicles of cymes, the bracts never enlarged; corolla lobes without apical extensions; persistent calyx inconspicuous or to 0.5 mm long ..... Group 7—*tenuifolia* group
7b. Inflorescences panicles of cymes or usually glomerules, the bracts often enlarged; corolla lobes almost always with apical extensions; persistent calyx often a conspicuous tube ..... Group 8—*calophylla* group

Species Group Synopses

Group 1—*carthagenensis* group. Species 1–7.

The *carthagenensis* group comprises seven species: *Psychotria carthagenensis*, *P. clivorum*, *P. lamarinensis*, *P. micrantha*, *P. neillii*, *P. quinqueradiata*, and *P. viridis*. The *Psychotria quinqueradiata* species complex includes that widespread species plus *P. lamarinensis*, which is endemic to northern Costa Rica. The *P. micrantha* complex includes that species plus *P. neillii*, whose range is restricted to Caribbean southern Nicaragua and northern Costa Rica. *Psychotria carthagenensis*, *P. clivorum*, and *P. viridis* are all widespread without obvious close relatives.

In addition to the key characters, members of this group may be recognized by their seeds having (3–)4–5 deep longitudinal furrows on the dorsal surface and 2 longitudinal furrows on the ventral surface.

Group 2—*costivenia* group. Species 8–16.

The *costivenia* group comprises nine species: *P. balancanensis*, *P. costivenia*, *P. fendleri*, *P. flava*, *P. grandis*, *P. horizontalis*, *P. papantlensis*, *P. pleuropoda*, and *P. sylvivaga*. *The Psychotria horizontalis* complex includes the most widespread of the nine plus *P. fendleri*, which is endemic to Caribbean coastal Panama. The *P. costivenia* complex comprises the other seven; *P. costivenia* is only slightly more widespread than *P. grandis*, with the two sharing noteworthy morphological similarity and overlapping ranges. *Psychotria sylvivaga* has been collected only in Costa Rica, and the remaining four species are restricted to southern Mexico, Guatemala, and Belize.

Distinctive character states, in addition to those in the key, include a usually conspicuous persistent calyx in fruit.

Group 3—*graciliflora* group. Species 17–25.

The *graciliflora* group comprises nine species in Mesoamerica: *P. bakeri*, *P. graciliflora*, *P. jimenezii*, *P. laselvensis*, *P. liesneri*, *P. marginata*, *P. orosiana*, *P. parvifolia*, and *P. philacra*. *Psychotria marginata* is the most widespread and frequently collected, and no other species closely resembles it morphologically. In contrast, the also widespread *P. graciliflora* is strikingly similar to six of the other species (the *P. graciliflora* complex) that occur more or less sympatrically with it: *P. parvifolia* and *P. orosiana* (Costa Rica and western Panama), *P. laselvensis* (Costa Rica), *P. bakeri* (Los Santos, Panama), *P. liesneri* (eastern Panama province), and *P. philacra* (eastern Darién, Panama, at higher elevation than *P. graciliflora*). *Psychotria jimenezii* may belong to this complex as well.

Members may be recognized by their key characters plus stipules often biacuminate to biaristate, secondary veins usually brochidodromous and diverging 70°–90°, and inflorescence secondary axes usually delicate.

Group 4—*remota* group. Species 26.

The *remota* group includes several species in South America but only one of those, *P. remota*, in Mesoamerica. An additional recognition character is the winged inflorescence axes, conspicuous especially in the field.

Group 5—*nervosa* group. Species 27–35.

The *nervosa* group comprises nine species: *P. aguilarii*, *P. boquetensis*, *P. chagrensis*, *P. erythrocarpa*, *P. fosteri*, *P. fruticetorum*, *P. jinotegensis*, *P. mirandae*, and *P. nervosa*. Two species complexes, those of *P. nervosa* and of *P. chagrensis*, are discernible; three other fairly widespread species—*P. fruticetorum*, *P. erythrocarpa*, and *P. jinotegensis*—do not closely resemble any others. The *P. nervosa* complex consists of widespread *P. nervosa* and three species of more restricted ranges, all of which occur allopatrically with or at range boundaries of *P. nervosa*: *P. mirandae* in southern Mexico, *P. aguilarii* in higher-elevation southern Guatemala, and *P. boquetensis* in high-elevation western Panama. The *P. chagrensis* complex includes widespread *P. chagrensis* and the probably derived *P. fosteri*, which occurs on Coiba Island, Panama, apparently allopatrically with respect to *P. chagrensis*.

Recognition characters not included in the key are ellipsoidal to narrow-ellipsoidal fruit, and inflorescences reduced to fascicles of flowers or the secondary axes in (2–)3 ranks.

Group 6—*panamensis* group. Species 36–47.

The *panamensis* group comprises 12 species in Mesoamerica: *P. cascajalensis*, *P. chiriquina*, *P. cocosensis*, *P. dwyeri*, *P. hornitensis*, *P. lundellii*, *P. mexiae*, *P. olgae*, *P. panamensis*, *P. sarapiquensis*, *P. stockwellii*, and *P. trichotoma*. The largest species complex is the *P. panamensis* complex. It includes one widespread species, *P. panamensis*, whose var. *ixtlanensis* may owe its origin to introgression from *P. trichotoma* (see under Systematic Treatment), and five narrow-ranging species: *P. dwyeri* (southern Mexico, sympatric with *P. panamensis*), *P. stockwellii* (Costa Rica and Panama, sympatric), *P. cocosensis* (Cocos Island, Costa Rica, allopatric), *P. olgae* (Panama, ± sympatric), and *P. cascajalensis* (Panama, sympatric). The widespread species *P. trichotoma*, *P. sarapiquensis*, and *P. mexiae* are of uncertain affinities; the former two may be closely related to the *P. panamensis* complex. The *P. chiriquina* complex includes two species whose ranges do not overlap (*P. lundellii* south to El Salvador and *P. chiriquina* south from northern Nicaragua) and one narrow endemic, *P. hornitensis* from high-elevation western Panama at the eastern end of the range of *P. chiriquina*.

Group 7—*tenuifolia* group. Species 48, 49.

The *tenuifolia* group includes only two species in Mesoamerica, *P. limonensis* and *P. tenuifolia*, both of which are widespread with extensively overlapping ranges. The group is characterized by minute flowers and secondary veins diverging usually 70°–90°, in addition to the key characters.

Group 8—*calophylla* group. Species 50–61.

The *calophylla* group comprises 12 species: *P. alfaroana*, *P. calophylla*, *P. chitariana*, *P. dressleri*, *P. hammelii*, *P. insignis*, *P. insueta*, *P. monteverdensis*, *P. pacorensis*, *P. psychotriifolia*, *P. rosulatifolia*, and *P. sixaolensis*. Ten of the species have small geographic ranges; only *P. calophylla* and *P. psychotriifolia* are at all widespread, and their ranges are notably discontinuous. *Psychotria dressleri* and *P. rosulatifolia* are quite similar morphologically and occur in eastern Panama, and therefore may be supposed to be related; but beyond that the affinities are very uncertain.

Additional recognition characters are many: herbaceous or suffrutescent habit; usual general pubescence; sheathing stipules, these usually bifurcate or biaristate with the extensions often from corners of the truncate sheath; and ellipsoidal fruit.

Myrstiphyllum P. Browne, Civ. Nat. Hist. Jamaica. 152. 1756 (nom. rejic.). Sensu Hitchcock, Annual Rep. Missouri Bot. Gard. 4: 95. 1893.

Psychotrophum P. Browne, Civ. Nat. Hist. Jamaica. 160, t. 13, fig. 1, t. 17, fig. 2. 1756 (nom. rejic.).

Mapouria Aubl., Hist. Pl. Guiane 1: 175, pl. 67. 1775. TYPE SPECIES: *Mapouria guianensis* Aubl. Sensu Oersted, Amér. Centr. 1863. Also sensu Mueller-Argoviensis, Flora 59: 457–466, 495–498. 1876, and in Martius, Fl. Bras. 6(5): 384–428. 1881. Also sensu Bremekamp, Recueil Trav. Bot. Néerl. 31: 248. 1934.

Uragoga Baillon, Adansonia 12: 323. 1879. TYPE SPECIES: *Uragoga ipecacuanha* (Brot. Baill.) Sensu Kuntze, Revis. Gen. Pl. 1: 298–301. 1891.

Shrubs, small trees, or less often herbs or subshrubs; stipules interpetiolar, often sheathing, usually caducous, leaving a pale ridge with red-brown fringe. *Leaves* opposite; blades membranous to coriaceous, drying red-brown or dull greenish or rarely chalky yellow-green; secondary veins eucamptodromous to brochidodromous, sometimes with collector vein, the axils sometimes with domatia or tufts of hairs; tertiary veins orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, panicles of cymes or of glomerules or rarely fascicles of flowers; secondary axes borne in 1–several ranks along the main axis, each rank with 1–3 often size-differentiated pairs of axes. *Flowers* small, (4–)5-merous, almost always distylous; corolla usually white, the tube cylindrical; style 2-branched, the branches bearing the stigmatic surfaces, the ovary 2-celled, the ovules 1 per cell, attached basally. *Fruit* fleshy, maturing red (except reportedly purple or blackish in *P. insueta* and *P. pacorensis*); persistent calyx often conspicuous at distal end of fruit; seeds 2, hemispherical in cross section, the rounded dorsal surface with 3–5 regular to many irregular longitudinal furrows, usually giving the dried fruit a costate aspect, the flat or slightly concave dorsal surface with (1–)2 regular longitudinal furrows often plus several shallow irregular furrows.

A pantropical subgenus of approximately 600 species worldwide, including ca. 200 species in the Neotropics, 61 of which are in Mesoamerica. The subgenus accounts for the majority of species in the Antilles but only for 32 of 242 species treated by Steyermark (1972) for the Guayana Highland.

KEY TO SPECIES OF
PSYCHOTRIA SUBGENUS *PSYCHOTRIA*

1a. Leaf blades with collector veins distinct, straight, or slightly undulating 2
1b. Leaf blades without collector veins 13
2a. Inflorescences reduced to fascicles of flowers 3
2b. Inflorescences with distinct axes 4
3a. Leaf blades (6–)8–12 × (2–)3–5 cm; stipule sheath 8–12 mm long; Coiba Island, Panama ..... (31) *P. fosteri*
3b. Leaf blades (3–)4–7.5(–9.5) × (1–)1.5–2.5(–3.5) cm; stipule sheath 4–7 mm long; widespread ..... (29) *P. chagrensis*
4a. Inflorescence a panicle of glomerules 5
4b. Inflorescence a panicle of cymes 9
5a. Young stems glabrous; western Costa Rica ..... (57) *P. monteverdensis*
5b. Young stems ferrugineous-pubescent or brown-puberulent 6
6a. Leaf blades ovate; secondary veins diverging over 90°; San Blas, Panama ..... (55) *P. insignis*
6b. Leaf blades elliptic or oblanceolate or obovate; secondary veins diverging less than 90° 7
7a. Treelet 3–8(–15) m tall; fruit 10–14 mm long; widespread ..... (51) *P. calophylla*
7b. Shrub or subshrub to 2 m tall; fruit less than 10 mm long 8
8a. Inflorescence lacking peduncle, often with more than 1 pair of secondary axes per rank; corolla tube 1.5 mm long; southern Nicaragua through Panama ..... (59) *P. psychotriifolia*
8b. Inflorescence with peduncle, with 1 pair of secondary axes per rank; corolla tube 4 mm long; Limón, Costa Rica, and Bocas del Toro, Panama ..... (61) *P. sixaolensis*
9a. Young stems ferrugineous-pubescent; inflorescence with secondary axes usually in more than 1 size-differentiated pair per rank; Costa Rica ..... (19) *P. jimenezii*
9b. Young stems glabrous or minute-puberulent; inflorescence with secondary axes in 1 pair or 2 usually equal pairs per rank 10
10a. Inflorescence with bracts 4 mm long; subshrubs or herbs 0.5 m tall; eastern Darién, Panama ..... (60) *P. rosulatifolia*
10b. Inflorescence with bracts to 1.2 mm long; shrubs 0.4–3(–5) m tall 11
11a. Leaves sessile with organic matter accumulating in leaf axils; leaf blades 30–42 cm long; Veraguas, Panama ..... (56) *P. insueta*
11b. Leaves petiolate, not as above; leaf blades to 29 cm long 12
12a. Leaves broad-elliptic, (12–)17–29 × (6–)7.5–15 cm; inflorescence secondary axes in (4–)5–6 ranks; fruit (3.5–)4(–4.5) × (3–)3.5(–4) mm; widespread ..... (48) *P. limonensis*
12b. Leaves narrow-elliptic, (4–)7.5–23 × (1–)2.5–6(–7.7) cm; inflorescence secondary axes in (2–)3(–4) ranks; fruit 4–5 × 3–4.5(–5) mm; widespread ..... (49) *P. tenuifolia*
13a. Fruit obloid (length < diameter); eastern Darién, Panama ..... (25) *P. philacra*
13b. Fruit length ≥ diameter 14
14a. Inflorescence not pedunculate (except rarely) 15
14b. Inflorescence pedunculate (except rarely) 37
15a. Inflorescence reduced to fascicles of flowers 16
15b. Inflorescence not reduced to fascicles of flowers 18
16a. Young stems red-brown tomentose; southern Mexico ..... (34) *P. mirandae*
16b. Young stems glabrous 17
17a. Leaf secondary veins 11–14, diverging 70°–80°; Coiba Island, Panama ..... (31) *P. fosteri*
17b. Leaf secondary veins 6–9(–10), diverging 45°–60°; widespread ..... (6) *P. quinqueradiata*
18a. Inflorescence secondary axes in 2 or more pairs per rank in at least 1 rank (except for rare inflorescences) or in a fascicle 19
18b. Inflorescence secondary axes only in 1 pair per rank (except for unusual inflorescences having 2 pairs in one rank) 23
19a. Young stems glabrous 20

19b. Young stems puberulent, tomentose, or ferrugineous-pubescent 21
20a. Leaf blades usually obovate or oblanceolate, (6–)9–15(–16) × (2–)3–7.5 cm, with secondary veins 6–9(–10) pairs diverging 45°–60°; corolla tubes 4–5 mm long; widespread ..... (6) *P. quinqueradiata*
20b. Leaf blades broad-elliptic, (13–)16–20 × (5–)7.5–9.5 cm, with secondary veins 9–11 pairs diverging 70°–85°; corolla tubes 3 mm long; Alajuela, Costa Rica ..... (3) *P. lamarinensis*
21a. Stipules 4–8 mm long; fruit red-brown tomentose; southern Mexico ..... (34) *P. mirandae*
21b. Stipules at least 10 mm long; fruit glabrous 22
22a. Fruit drying often shiny red-brown; secondary veins often drying reddish below; corolla often drying pink; Mexico through northern Costa Rica ..... (42) *P. mexiae*
22b. Fruit drying dull red-brown or red-black; secondary veins and corolla not as above; widespread ..... (44) *P. panamensis*
23a. Young stems obviously ferrugineous-pubescent or tomentose 24
23b. Young stems glabrous or minutely puberulent 28
24a. Calyx lobes conspicuous, ≥ 0.5 mm long 25
24b. Calyx lobes inconspicuous, ≤ 0.3 mm long 26
25a. Bark longitudinally grooved; stipules bilobed; inflorescence main axis 1.2–2 cm long; Chiriquí, Panama ..... (28) *P. boquetensis*
25b. Bark smooth; stipules not bilobed; inflorescence main axis (2.5–)4–6.5 cm long; Guatemala through Nicaragua ..... (33) *P. jinotegensis*
26a. Leaf blades (1–)1.5–5.2 cm long, the secondary veins inconspicuous to not evident below; Costa Rica and western Panama ..... (24) *P. parvifolia*
26b. Leaf blades at least (6–)9 cm long, the secondary veins conspicuous below 27
27a. Stipules (10–)20–80 mm long; corolla tube diameter greater than half its length; seed dorsal surface with 4 or 7–10 irregular longitudinal furrows; widespread ..... (44) *P. panamensis*
27b. Stipules 6–11 mm long; corolla tube diameter less than half its length; seed dorsal surface with 4–5 regular longitudinal furrows; widespread ..... (35) *P. nervosa*
28a. Persistent calyx cuplike, coriaceous, 1.5 mm long; Cocos Island, Costa Rica ..... (38) *P. cocosensis*
28b. Persistent calyx inconspicuous or a beak to 1 mm long 29
29a. Fruit when dry obovoid or, if ellipsoidal, at least 7 mm long and with inflorescence axes in 3–5 ranks 30
29b. Fruit when dry ellipsoidal or spherical, seldom over 7 mm long and then with inflorescence secondary axes in 5–7 ranks 32
30a. Leaf secondary veins 6–9(–11); Veracruz, Mexico, Costa Rica, and Panama ..... (45) *P. sarapiquensis*
30b. Leaf secondary veins at least 12 31
31a. Leaf blades wide (length/width approximately 2); southern Mexico through Nicaragua ..... (47) *P. trichotoma*
31b. Leaf blades narrow (length/width approximately 3); Oaxaca, Mexico ..... (44b) *P. panamensis* var. *ixtlanensis*
32a. Bark smooth 33
32b. Bark with longitudinal ridges, fissures, or furrows 34
33a. Fruit spherical; southern Mexico ..... (39) *P. dwyeri*
33b. Fruit narrow ellipsoidal; widespread ..... (35) *P. nervosa*
34a. Stipules no more than 10 mm long 35
34b. Stipules rarely as short as 10 mm 36
35a. Inflorescence secondary axes in 2 ranks; corolla tube 3–3.5 mm long; Guatemala ..... (27) *P. aguilarii*
35b. Inflorescence secondary axes in 3 (or 4) ranks; corolla tube 4–6 mm long; Nicaragua through western Panama ..... (37) *P. chiriquina*
36a. Fruit drying often shiny red-brown; secondary veins often drying reddish below; corolla often drying pink; Mexico through northern Costa Rica ..... (42) *P. mexiae*
36b. Fruit drying dull red-brown or red-black; secondary veins and corolla not as above; widespread ..... (44) *P. panamensis*
37a. Inflorescence a panicle of glomerules 38
37b. Inflorescence a panicle of cymes 47
38a. Leaf secondary veins > 10 39
38b. Leaf secondary veins ≤ 10 42
39a. Shrub or subshrub to 1.5 m tall; corolla lobes with apical appendages; eastern Panama ..... (53) *P. dressleri*
39b. Shrub or tree rarely less than 2 m tall; corolla lobes without appendages 40
40a. Young stems and leaf undersides densely ferrugineous-pubescent; fruit when dry 4 mm long; Guatemala, Nicaragua through Panama ..... (4) *P. micrantha*
40b. Young stems and leaf undersides glabrous, puberulent, or short ferrugineous-puberulent; fruit when dry not less than 4.5 mm long 41
41a. Inflorescence main axis (9–)13–26 cm long; leaves often drying chalky yellow-green above; fruit when dry 8–12(–13) mm long; southern Mexico and Guatemala ..... (11) *P. flava*
41b. Inflorescence main axis 1.5–12 cm long; leaves drying red-brown to green-brown; fruit when dry 4.5–8 mm long; widespread ..... (44) *P. panamensis*
42a. Bark smooth 43
42b. Bark furrowed or ridged longitudinally 45
43a. Inflorescence with secondary axes in (second to) fourth rank and above reduced so that flowers and fruit appear clustered along main axis; widespread ..... (7) *P. viridis*
43b. Inflorescence not as above 44
44a. Tree 10 m tall; leaf blades coriaceous; inflorescence main axis 6 cm long; Coclé, Panama ..... (36) *P. cascajalensis*
44b. Shrub to 1.5 m tall; leaf blades membranous; inflorescence main axis 1.5–3.5 cm long; Los Santos, Panama ..... (17) *P. bakeri*
45a. Leaf blades coriaceous, the margins inrolled; fruit when dry 9–10 mm long; Panamá Province, Panama ..... (43) *P. olgae*

45b. Leaf blades membranous to subcoriaceous, the margins not inrolled; fruit when dry up to 8 mm long 46
46a. Stipules 8–12 × 1.5–2 mm, not sheathing; inflorescence secondary axes in (2 or) 3 ranks; seed dorsal surface with 4 regular longitudinal furrows; southern Mexico, Guatemala, Belize ..... (30) *P. erythrocarpa*
46b. Stipules (10–)20–80 × (2.5–)3.5–7 mm, sheathing; inflorescence secondary axes in 3–7(–8) ranks; seed dorsal surface with 4 or 7–10 irregular longitudinal furrows; widespread ..... (44) *P. panamensis*
47a. Inflorescence axes winged; Costa Rica and Panama ..... (26) *P. remota*
47b. Inflorescence axes not winged 48
48a. Leaf secondary veins brochidodromous with secondary loops conspicously far from margin 49
48b. Leaf secondary veins eucamptodromous or else brochidodromous with secondary loops near margin 50
49a. Leaves membranous, drying dull green to red-brown; calyx lobes lanceolate, 1–2 mm long, often to 3(–5) mm long and more conspicuous in fruit; widespread ..... (13) *P. horizontalis*
49b. Leaves coriaceous, drying bright chalky yellow-green above; calyx lobes triangular, 0.5 mm long, to 1.5 mm long in fruit; near Colón, Panama ..... (10) *P. fendleri*
50a. At least half of inflorescences having at least one rank of 4 or 6 secondary axes in size-differentiated pairs (e.g., one longer, one shorter) 51
50b. Inflorescence having ranks with either 2 secondary axes or 4 equal axes or a cluster of axes, only rarely with 4 size-differentiated axes 65
51a. Stipules with paler central triangle or keel, often persistent at terminal 2–6 nodes 52
51b. Stipules without paler central triangle or keel, caducous 55
52a. Dorsal seed surface with 10–15 irregular longitudinal furrows, making dry fruit appear smooth; inflorescence main axis 18–33 cm long; widespread ..... (12) *P. grandis*
52b. Dorsal seed surface with 4–5 regular longitudinal furrows, making dry fruit appear ridged; inflorescence main axis 1.5–22 cm long 53
53a. Inflorescence secondary axes in 1 or 2 ranks; Tabasco, Mexico, Guatemala, and Belize ..... (15) *P. pleuropoda*
53b. Inflorescence secondary axes in (2–)3–4(–5) ranks 54
54a. Leaf blades thin membranous; corolla tube 4–5 mm long; calyx drying conspicuously pale in flower and fruit; southern Mexico, Guatemala, Belize ..... (14) *P. papantlensis*
54b. Leaf blades membranous to subcoriaceous; corolla tube 2–3.5 mm long; calyx not drying conspicuously pale; Mexico through Nicaragua ..... (9) *P. costivenia*
55a. Leaf blades conspicuously coriaceous; corolla tube 1.5 × 1.5 mm; Coclé, Panama ..... (36) *P. cascajalensis*
55b. Leaf blades membranous or chartaceous or subcoriaceous; corolla tube at least 2 mm long or, if 1.5 mm long, the length > diameter 56
56a. Young stems ferrugineous-pubescent; dorsal seed surface with 3 deep longitudinal furrows; Caribbean Nicaragua and Costa Rica ..... (5) *P. neillii*
56b. Young stems glabrous or puberulent; dorsal seed surface not as above 57
57a. Fruit when dry spherical, appearing smooth on outside; southern Mexico through El Salvador ..... (41) *P. lundellii*
57b. Fruit when dry ellipsoidal or, if spherical, with conspicuous longitudinal ridges on outside 58
58a. Young stems red-brown puberulent 59
58b. Young stems glabrous 60
59a. Inflorescence main axis 6–8.5 cm long; persistent calyx not evident or a minute beak; leaf secondary veins diverging 55°–70°; widespread ..... (2) *P. clivorum*
59b. Inflorescence main axis 4.5 cm long; persistent calyx a cup ca. 0.5 mm long; leaf secondary veins diverging 70°–80°; eastern Panamá Province, Panama ..... (58) *P. pacorensis*
60a. Inflorescence secondary axes in 2 ranks conspicuously near the apex of the main axis; Tabasco, Mexico ..... (8) *P. balancanensis*
60b. Inflorescence secondary axes in ranks spaced ± evenly along the main axis 61
61a. Leaves drying green-black or red-black 62
61b. Leaves drying yellow-green to green-brown to red-brown to red-gray, never black 63
62a. Mature leaf blades to 13(–16) cm long; secondary veins (8–)10–13 pairs; corolla tube 2.5–3 mm long; Heredia, Costa Rica ..... (20) *P. laselvensis*
62b. Mature leaf blades to 10.5 cm long; secondary veins 7–9 pairs; corolla tube 2.5–5 mm long; Costa Rica and western Panama ..... (23) *P. orosiana*
63a. Fruit spherical to slightly ellipsoidal, 3.5–4 mm long, drying black; widespread ..... (22) *P. marginata*
63b. Fruit ellipsoidal, 4–5.5(–6) mm long, drying red-brown 64
64a. Corolla tube 2 × 1.5 mm; leaf secondary veins (4–)5–7(–8), the axils often with minute tufts of white hairs below; widespread ..... (32) *P. fruticetorum*
64b. Corolla tube 2.5–3 × 1.5 mm; leaf secondary veins 7–10, the axils lacking domatia or hairs; widespread ..... (1) *P. carthagenensis*
65a. Inflorescence secondary axes clustered terminally on the main axis 66
65b. Inflorescence secondary axes disposed in regular ranks along the main axis 67
66a. Leaf blades 28–33 × 13–15 cm, the secondary veins 16–19; inflorescence main axis 7.5 cm long; Cartago, Costa Rica ..... (52) *P. chitariana*
66b. Leaf blades 11–29 × 4.5–10 cm, the secondary veins (7–)11–14(–16); inflorescence main axis (1–)2–4 cm long; Costa Rica ..... (50) *P. alfaroana*
67a. Herb or subshrub 0.1–0.3 m tall; leaf blades bullate; western Panama ..... (54) *P. hammelii*
67b. Shrub or tree at least 1 m tall; leaf blades not bullate 68

68a. Leaf blades small and narrow, 2.5–3.5 × 0.5–0.7 cm; inflorescence with fewer than 10 flowers; Chiriquí, Panama ..... (40) *P. hornitensis*
68b. Leaf blades usually longer and always wider than above; inflorescence of more than 10 flowers 69
69a. Leaf secondary veins (4–)5–8(–9) and diverging (67°–)70°–80°(–95°); leaf blades membranous; corolla tube 2–2.5 mm long; widespread ..... (18) *P. graciliflora*
69b. Leaf secondary veins not as above or, if so, the blades subcoriaceous with margins inrolled or the corolla tube 2.5–5 mm long 70
70a. Fruit when dry spherical 71
70b. Fruit when dry ellipsoidal or obovoid 75
71a. Fruit drying black 72
71b. Fruit drying red-brown 74
72a. Young stems glabrous, the bark smooth; fruit 3.5–4 mm long; widespread .. (22) *P. marginata*
72b. Young stems puberulent, the bark fissured or furrowed longitudinally; fruit only rarely less than 4.5 mm long 73
73a. Persistent calyx conspicuous, 1 mm long; leaf blades (8.5–)10–17 cm long; Costa Rica ..... (16) *P. sylvivaga*
73b. Persistent calyx inconspicuous; leaf blades (4–)4.5–6(–6.7) cm long; eastern Panamá Province, Panama ..... (21) *P. liesneri*
74a. Leaf blades (12–)15–23 cm long, drying green-brown; secondary veins (12–)15–18; southern Mexico ..... (39) *P. dwyeri*
74b. Leaf blades (5–)7.5–15 cm long, drying pale to glossy red-brown; secondary veins (5–)6–8(–12); Mexico through El Salvador ..... (41) *P. lundellii*
75a. Leaf secondary veins diverging 80°–90°; Costa Rica and Panama ..... (23) *P. orosiana*
75b. Leaf secondary veins diverging almost always < 75° 76
76a. Inflorescence secondary axes diverging over 90°; Costa Rica and Chiriquí, Panama ..... (46) *P. stockwellii*
76b. Inflorescence secondary axes diverging less than 90° 77
77a. Persistent calyx conspicuous, 1–3 mm long; Guatemala through Nicaragua ..... (33) *P. jinotegensis*
77b. Persistent calyx inconspicuous or a beak never longer than 1 mm 78
78a. Young stems usually tomentose; stipules lanceolate, not sheathing; Mexico, Guatemala, Belize ..... (30) *P. erythrocarpa*
78b. Young stems glabrous or puberulent or ferrugineous-puberulent; stipules sheathing 79
79a. Leaf blade length/width ≥ 3 80
79b. Leaf blade length/width < 3 81
80a. Fruit when dry 7–8 mm long; bark smooth; Mexico, Costa Rica, Panama ..... (45) *P. sarapiquensis*
80b. Fruit when dry 5–6 mm long; bark deeply fissured longitudinally; Nicaragua through Panama ..... (37) *P. chiriquina*
81a. Fruit when dry obovoid, usually black; southern Mexico through Nicaragua ..... (47) *P. trichotoma*
81b. Fruit when dry ellipsoidal, usually red-brown; widespread ..... (44) *P. panamensis*

Group 1. The *carthagenensis* Group

Shrub or sometimes small tree; young stems glabrous or sometimes puberulent or ferrugineous-pubescent; stipules usually sheathing, ovate (Fig. 2) or rarely lanceolate, the apex often acuminate or rarely biacuminate, uniform in color (except *P. viridis* with a darker central triangle), glabrous or sometimes puberulent or ferrugineous-pubescent, sometimes fringed, caducous (Fig. 1). *Leaf* blades usually obovate to elliptic, less commonly oblanceolate, *drying reddish or greenish brown or gray*; secondary veins 6–15 (except (18–)20–26 in *P. micrantha*) pairs, diverging 45°–70°(–85°), eucamptodromous (Fig. 3) or less commonly brochidodromous, the axils usually lacking domatia (except *P. quinqueradiata* and *P. viridis*; Fig. 4); tertiary veins orthogonal reticulate (except percurrent in *P. micrantha* and *P. neillii*; Fig. 5b). *Inflorescences* panicles of cymes or, less commonly, of glomerules (*P. micrantha* and *P. viridis*), pedunculate except for *P. lamarinensis* and *P. quinqueradiata* (Fig. 7g); *secondary axes usually in 2 (or 3) size-differentiated pairs per rank* (Fig. 7a) or sometimes in 4 equal axes per rank (*P. lamarinensis* and *P. quinqueradiata*) or sometimes in 1 pair per rank; bracts not conspicuously enlarged. *Corolla* tubes (1.5–)2–5 mm long, the lobes without apical extensions. *Fruit* when dry ellipsoidal or rarely obovoid; persistent calyx a beak (Fig. 9a) or not evident or rarely (*P. micrantha*) a tube ca. 0.5 mm long; *seed dorsal surface with (3–) 4–5 deep longitudinal furrows, the ventral surface with 2 deep or sometimes shallow longitudinal furrows* (Fig. 10a).

This group includes two pairs of very similar species plus the three other widespread species of unclear affinities, *Psychotria carthagenensis*, *P. clivorum*, and *P. viridis* (Figs. 13, 14). The first pair, the *P. quinqueradiata* complex, includes its widespread namesake plus *P. lamarinensis*, which is endemic to northern Costa Rica (Fig. 15); they share the following distinctive character states: inflorescences lacking peduncles, and inflorescence secondary axes 4 (not size-differentiated) per rank (Fig. 7g). The *P. micrantha* complex—including the widespread *P. micrantha* and *P. neillii*, this endemic to Caribbean southern Nicaragua and northern Costa Rica (Fig. 14)—shares a general ferrugineous vesture, biacuminate stipule apices, percurrent tertiary veins, and shallow longitudinal furrows on the seed ventral surfaces.

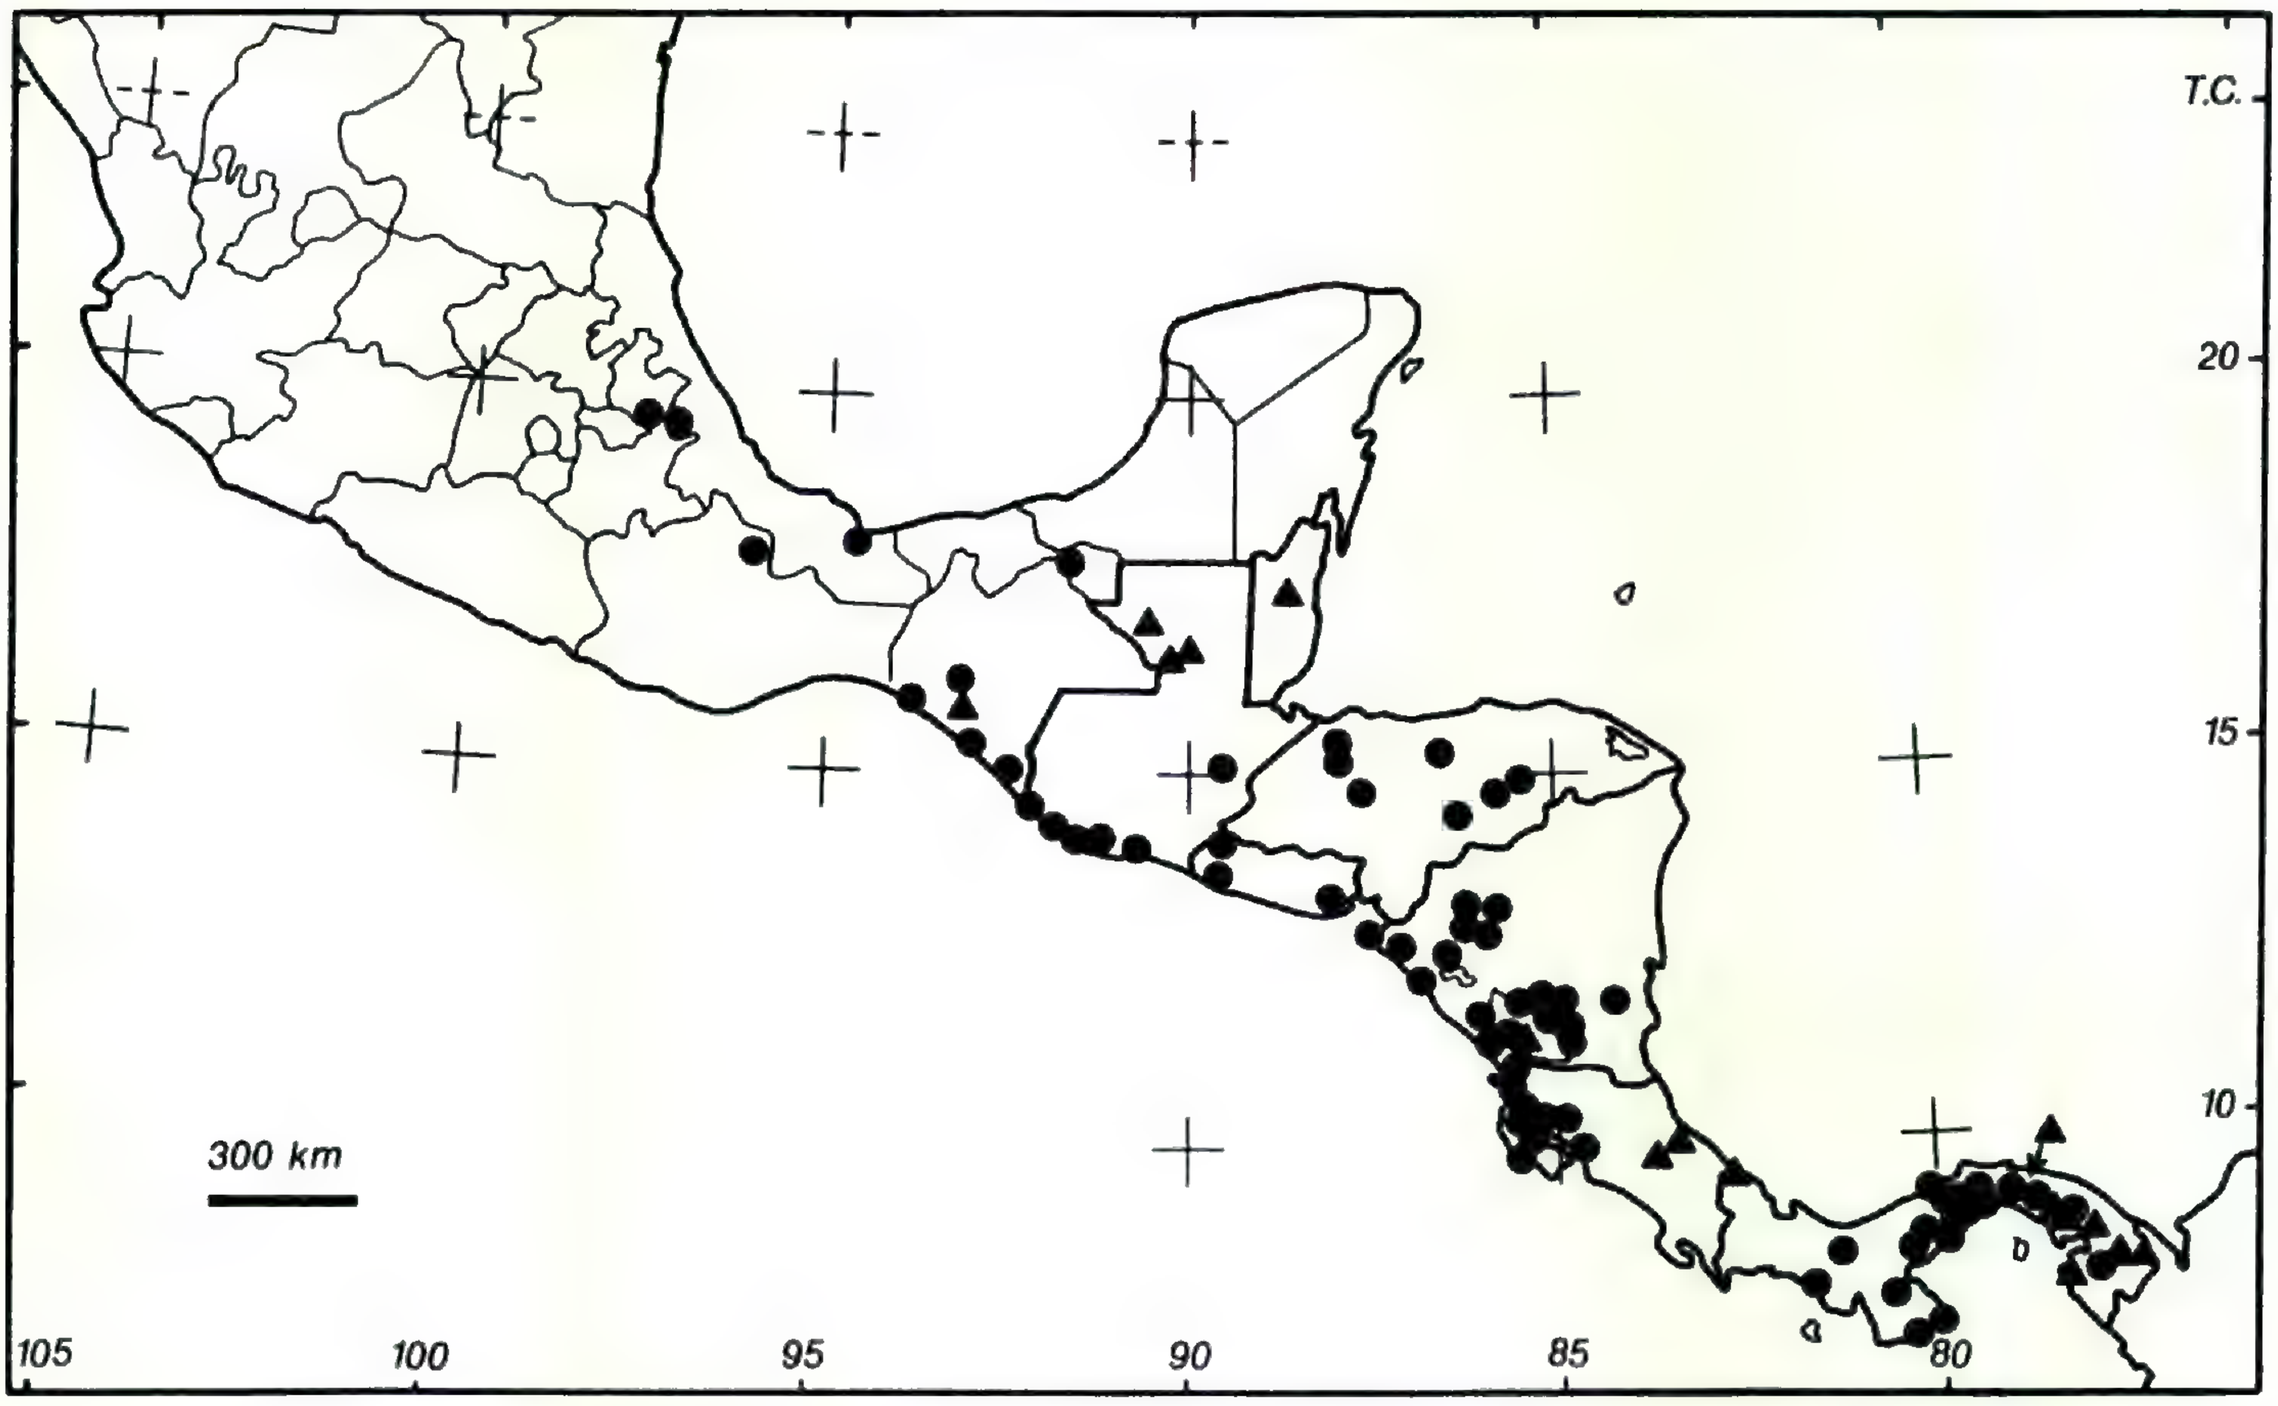

FIGURE 13. Distributions of *Psychotria carthagenensis* (circles) and *P. viridis* (triangles) in Mesoamerica.

Of the seven species in the group, four are apparently normally distylous and one, *Psychotria viridis*, is homostylous (at least in Mesoamerica). The two remaining species are too little collected to determine whether they are distylous or thrum-monomorphic.

1. Psychotria carthagenensis Jacquin, Enum. Syst. Pl. Carib. 16. 1760. Cf. also Select. Stirp. Amer. Hist. 174, fig. 22. 1788. *Uragoga carthagenensis* (Jacq.) O. Kuntze, Revis. Gen. Pl. 2: 959. 1891. *Psychotria carthaginensis* auctt. TYPE: Colombia. Bolívar: Cartagena (fr). (Type material not seen; locality and figure adequate to establish identity.) Figures 1, 2a, 3a, 7a, 9a, 10a, 13.

Psychotria sagraeana Urban, Symb. Antill. 7: 450. 1913. TYPE: Cuba. *Wright 3588* (syntype, US).

Shrub (0.5–)1–3(–6) m tall; young stems glabrous, the bark smooth to irregularly furrowed; stipules sheathing, ovate, 6–8 × 3–5 mm (Fig. 2), irregularly fringed, glabrous, caducous, leaving a pale ridge usually with red-brown fringe (Fig. 1). *Leaves* subsessile to petiolate; petioles to 5(–10) mm long, glabrous, flat above; blades membranous, obovate or rarely elliptic, the apex acuminate, the base attenuate, (6–)7.5–13(–16) × (2–)2.5–5.5(–6) cm, glabrous above and below, drying red-brown to red-gray; secondary veins 7–10 pairs, diverging 60°–70°(–75°), eucamptodromous (Fig. 3), constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes (Fig. 7a); panicle branched to 3 or 4 degrees; main axis (2–)3.5–8 cm long, the peduncle 1.5–5 cm long; secondary axes in 3(–4) ranks, the first-rank axes 4, the longer pair 1–2.7 cm long, the shorter pair 0.4–1.5 cm long, the second-rank axes (2 or) 4, the longer pair 0.4–1.5 cm long, the shorter pair 0.3–0.8 cm long, the third-rank axes 2 (or 4), the longer pair 0.3–1.0 cm long, the shorter pair 0.1–0.3 cm long, the fourth-rank axes 2, 0.3–0.4 cm long; cymes branched to (2–)3 degrees; bracts and bracteoles prominent, triangular, 1 × 1 mm, the bracts sometimes enlarged to 8 mm long, caducous, glabrous, fringed. *Flowers* sessile to subpedicellate, the pedicels to 0.5 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular, minute, glabrous; corolla white, the tube cylindrical, 2.5–3 × 1.5 mm, white pubescent in throat, the lobes linear, 1.5–2 × 1 mm; stamens 5, the filaments 3 mm long in pins, 3.5–4.5 mm long in thrums, the anthers 1 mm long; style 5–5.5 mm long in pins, 3–3.5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal, 4.5–5.5(–6) mm long, 3.5–4.5 mm diam., maturing red, drying red-brown; persistent calyx

not evident or sometimes a beak (Fig. 9a); seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 deep longitudinal furrows (Fig. 10a).

Distribution (Fig. 13). Common throughout Mexico and Central America, occurring also in Florida (cultivated), Cuba, Colombia, Venezuela, the Guianas, Ecuador, Peru, Brazil, Bolivia, Paraguay, Argentina, and Uruguay. In Central America it is found mostly in Pacific coastal lowlands at elevations of 0–1,400 m, mostly under 400 m, in tropical moist to premontane moist and wet forest with equatorial to tropical climates. It has been collected in flower December–August, primarily February–June, and in fruit throughout the year, primarily September–February.

Modern authors have perpetuated an early misspelling of the specific epithet by spelling it "*carthaginensis*" instead of the correct original "*carthagenensis*" (D. Nicolson, pers. comm.). A collection by Vahl, from the type region of Cartagena, resides in Berlin (*Willdenow 4083*) and has been annotated as *P. carthagenensis*; it is, however, *P. nervosa* and is clearly not the type of Jacquin's species.

Psychotria carthagenensis may be recognized by its obovate leaves drying dull red-brown, eucamptodromous secondary venation (Fig. 3), secondary inflorescence axes in two unequal pairs per rank (Fig. 7a), corolla drying red, ellipsoidal fruit drying reddish, and seed in cross section with the dorsal surface having four deep furrows and the ventral surface having two deep furrows (Fig. 10a). It is expected that careful analysis will reveal that this species exhibits more primitive character states than any other neotropical species in the subgenus. Mexican and Guatemalan collections suggest that the leaf blades are larger there than elsewhere in Central America.

2. Psychotria clivorum Standley & Steyermark, Publ. Field Mus. Nat. Hist., Bot. Ser. 23: 87. 1944. Based on *Psychotria limonensis* var. *angustifolia* Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 17: 282. 1937 (see protologue of *P. clivorum*). TYPE: Guatemala. Suchitepéquez: Finca Mocá, 1,020 m, 7 Jan. 1935 (fl), *Skutch 2073* (holotype, F; isotype, A). Figure 14.

Shrub or small tree, 2.5–6 m tall; young stems red-brown puberulent, the bark smooth to irregularly furrowed; stipules sheathing, ovate, the apex sometimes biaristate, 8–9(–14) × 4–4.5(–5) mm, glabrous to puberulent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 4–10 mm long, glabrous, grooved above; blades membranous, elliptic, the apex cuspidate, the base attenuate, (9–)12–22 × (3–)4–6.5(–8.5) cm, glabrous above, glabrous below with the midvein sometimes sparsely puberulent, drying red-gray to gray-green; secondary veins 9–13 pairs, diverging 55°–70°, eucamptodromous to brochidodromous, straight then arcuate near margin, prominulous below, glabrous to minute puberulent below, the axils lacking domatia or hairs; tertiary veins evident to conspicuous, orthogonal reticulate to slightly percurrent. *Inflorescences* terminal or pseudoaxillary, elongate panicles of cymes; panicle branched to 4 degrees; main axis 6–8.5 cm long, the peduncle 2.5–5 cm long; secondary axes in (3–)4(–5) ranks, the first-rank axes 4 or rarely 2, the longer pair 1.5–2.5 cm long, the shorter pair 0.6–1.5 cm long, the second-rank axes 4, the longer pair 0.8–1.3 cm long, the shorter pair 0.4–1 cm long, the third-rank axes 2 or 4, the longer pair 0.4–0.7 cm long, the shorter pair 0.1–0.3 cm long, the fourth-rank axes 2, 0.3–0.6 cm long, the fifth-rank axes 2, 0.3 cm long; cymes branched to 1–3 degrees; bracts linear, to 2 mm long, puberulent; bracteoles minute, irregular, to 0.6 mm long, puberulent. *Flowers* sessile to subpedicellate, the pedicels to 1 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 5, triangular to barely evident, to 0.3 mm long, puberulent; corolla white, the tube cylindrical to campanulate, 2–2.5 × 1.5 mm, white pubescent in throat, the lobes 5, linear, 2 × 0.8 mm; stamens 5, the filaments 2.5 mm long in pins, 3.5–4 mm long in thrums, the anthers 1 mm long; style 3.5–4 mm long in pins, 2–2.5 mm long in thrums, the branches short, clublike. *Fruit* when dry ellipsoidal, 5–6 mm long, 4–4.5 mm diam., maturing red, drying deep red-brown; persistent calyx not evident or sometimes a beak; seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 14). Not commonly collected but widespread from southern Mexico to western Panama, occurring at low elevations, 0–200 m, in Veracruz and Oaxaca, Mexico, and Bocas del Toro, Panama, and higher elevations, 600–1,400 m, in other parts of the range. It has been found in tropical moist and premontane rain

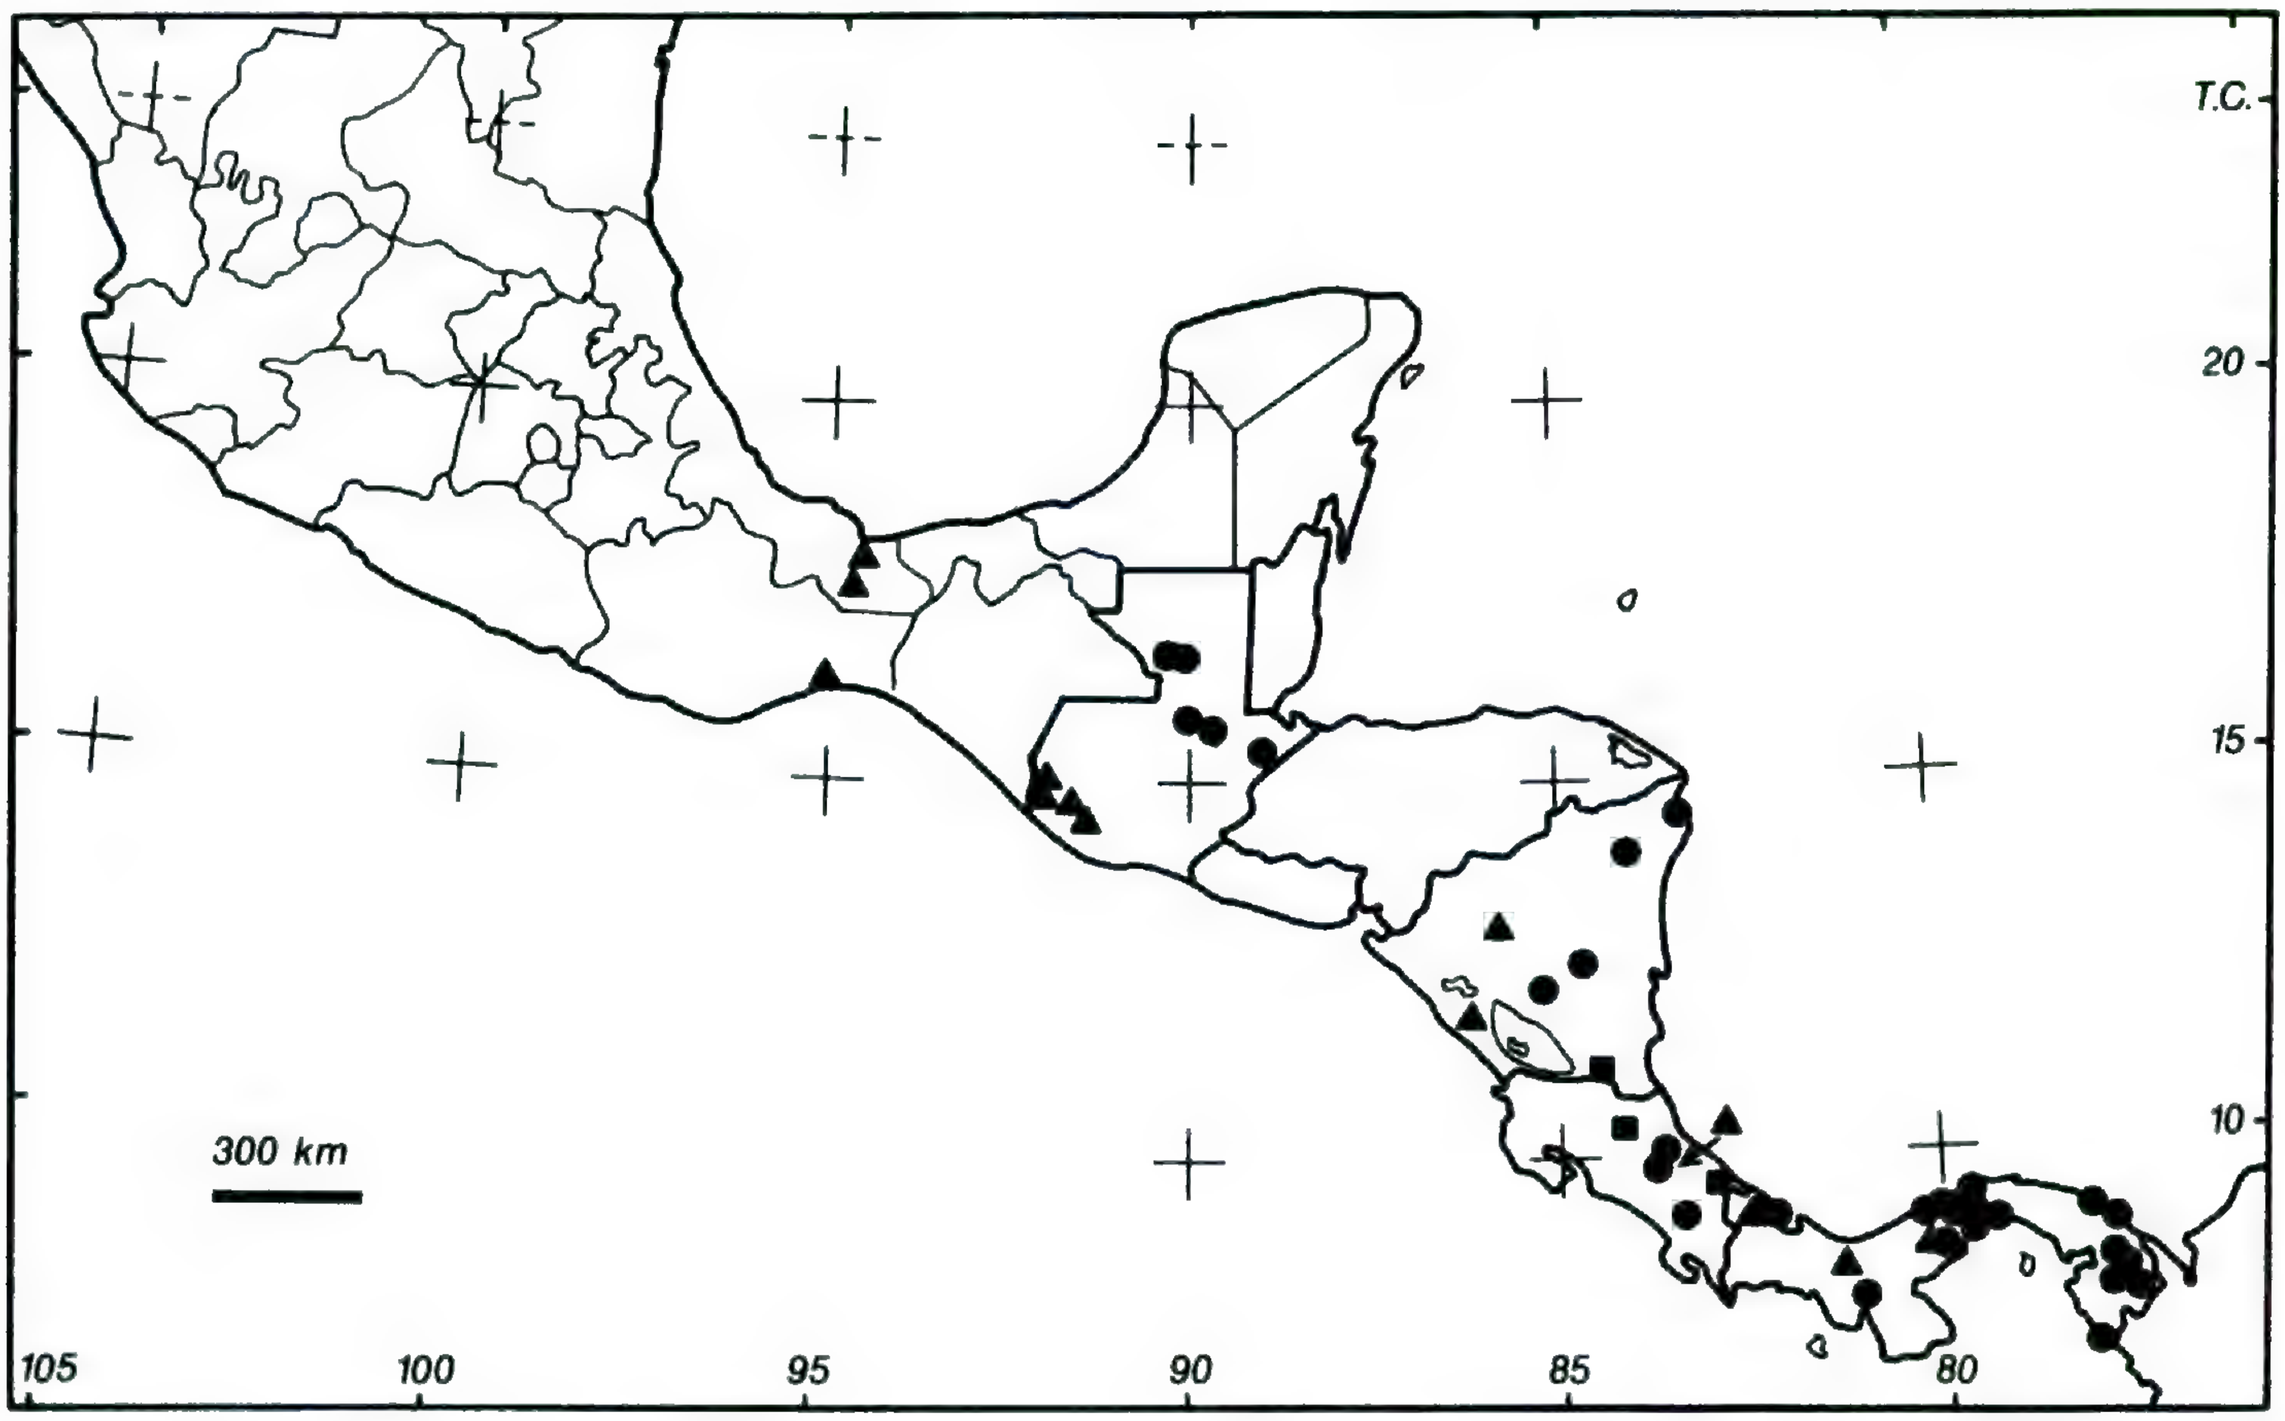

FIGURE 14. Distributions of *Psychotria clivorum* (triangles), *P. micrantha* (circles), and *P. neillii* (squares) in Mesoamerica.

forest with equatorial to tropical climate. It has been collected in flower January–May, especially March–April, and in fruit November–March.

Psychotria clivorum may be recognized by its elliptic leaves drying red-gray to gray-green, secondary veins well-spaced and diverging 55°–70°, inflorescence secondary axes in two unequal pairs per rank, the higher ranks decreasing in size uniformly, corolla drying red, ellipsoidal fruit, and seed cross section with four deep longitudinal furrows on the dorsal surface and two deep longitudinal furrows on the ventral surface. *Psychotria clivorum* shares many character states with *P. carthagenensis*, but the former differs in having stipules often biaristate, larger elliptic (versus obovate) leaf blades, more secondary veins, often brochidodromous secondary venation, and larger inflorescences.

Stipule morphology varies geographically, as Guatemalan plants appear more often biaristate while Nicaraguan plants have exceptionally large stipules. Secondary venation is generally eucamptodromous, but in Nicaragua the secondary loops are sufficiently robust to appear brochidodromous.

3. Psychotria lamarinensis C. Hamilton, Phytologia 64: 227. 1988. TYPE: Costa Rica. Ala-

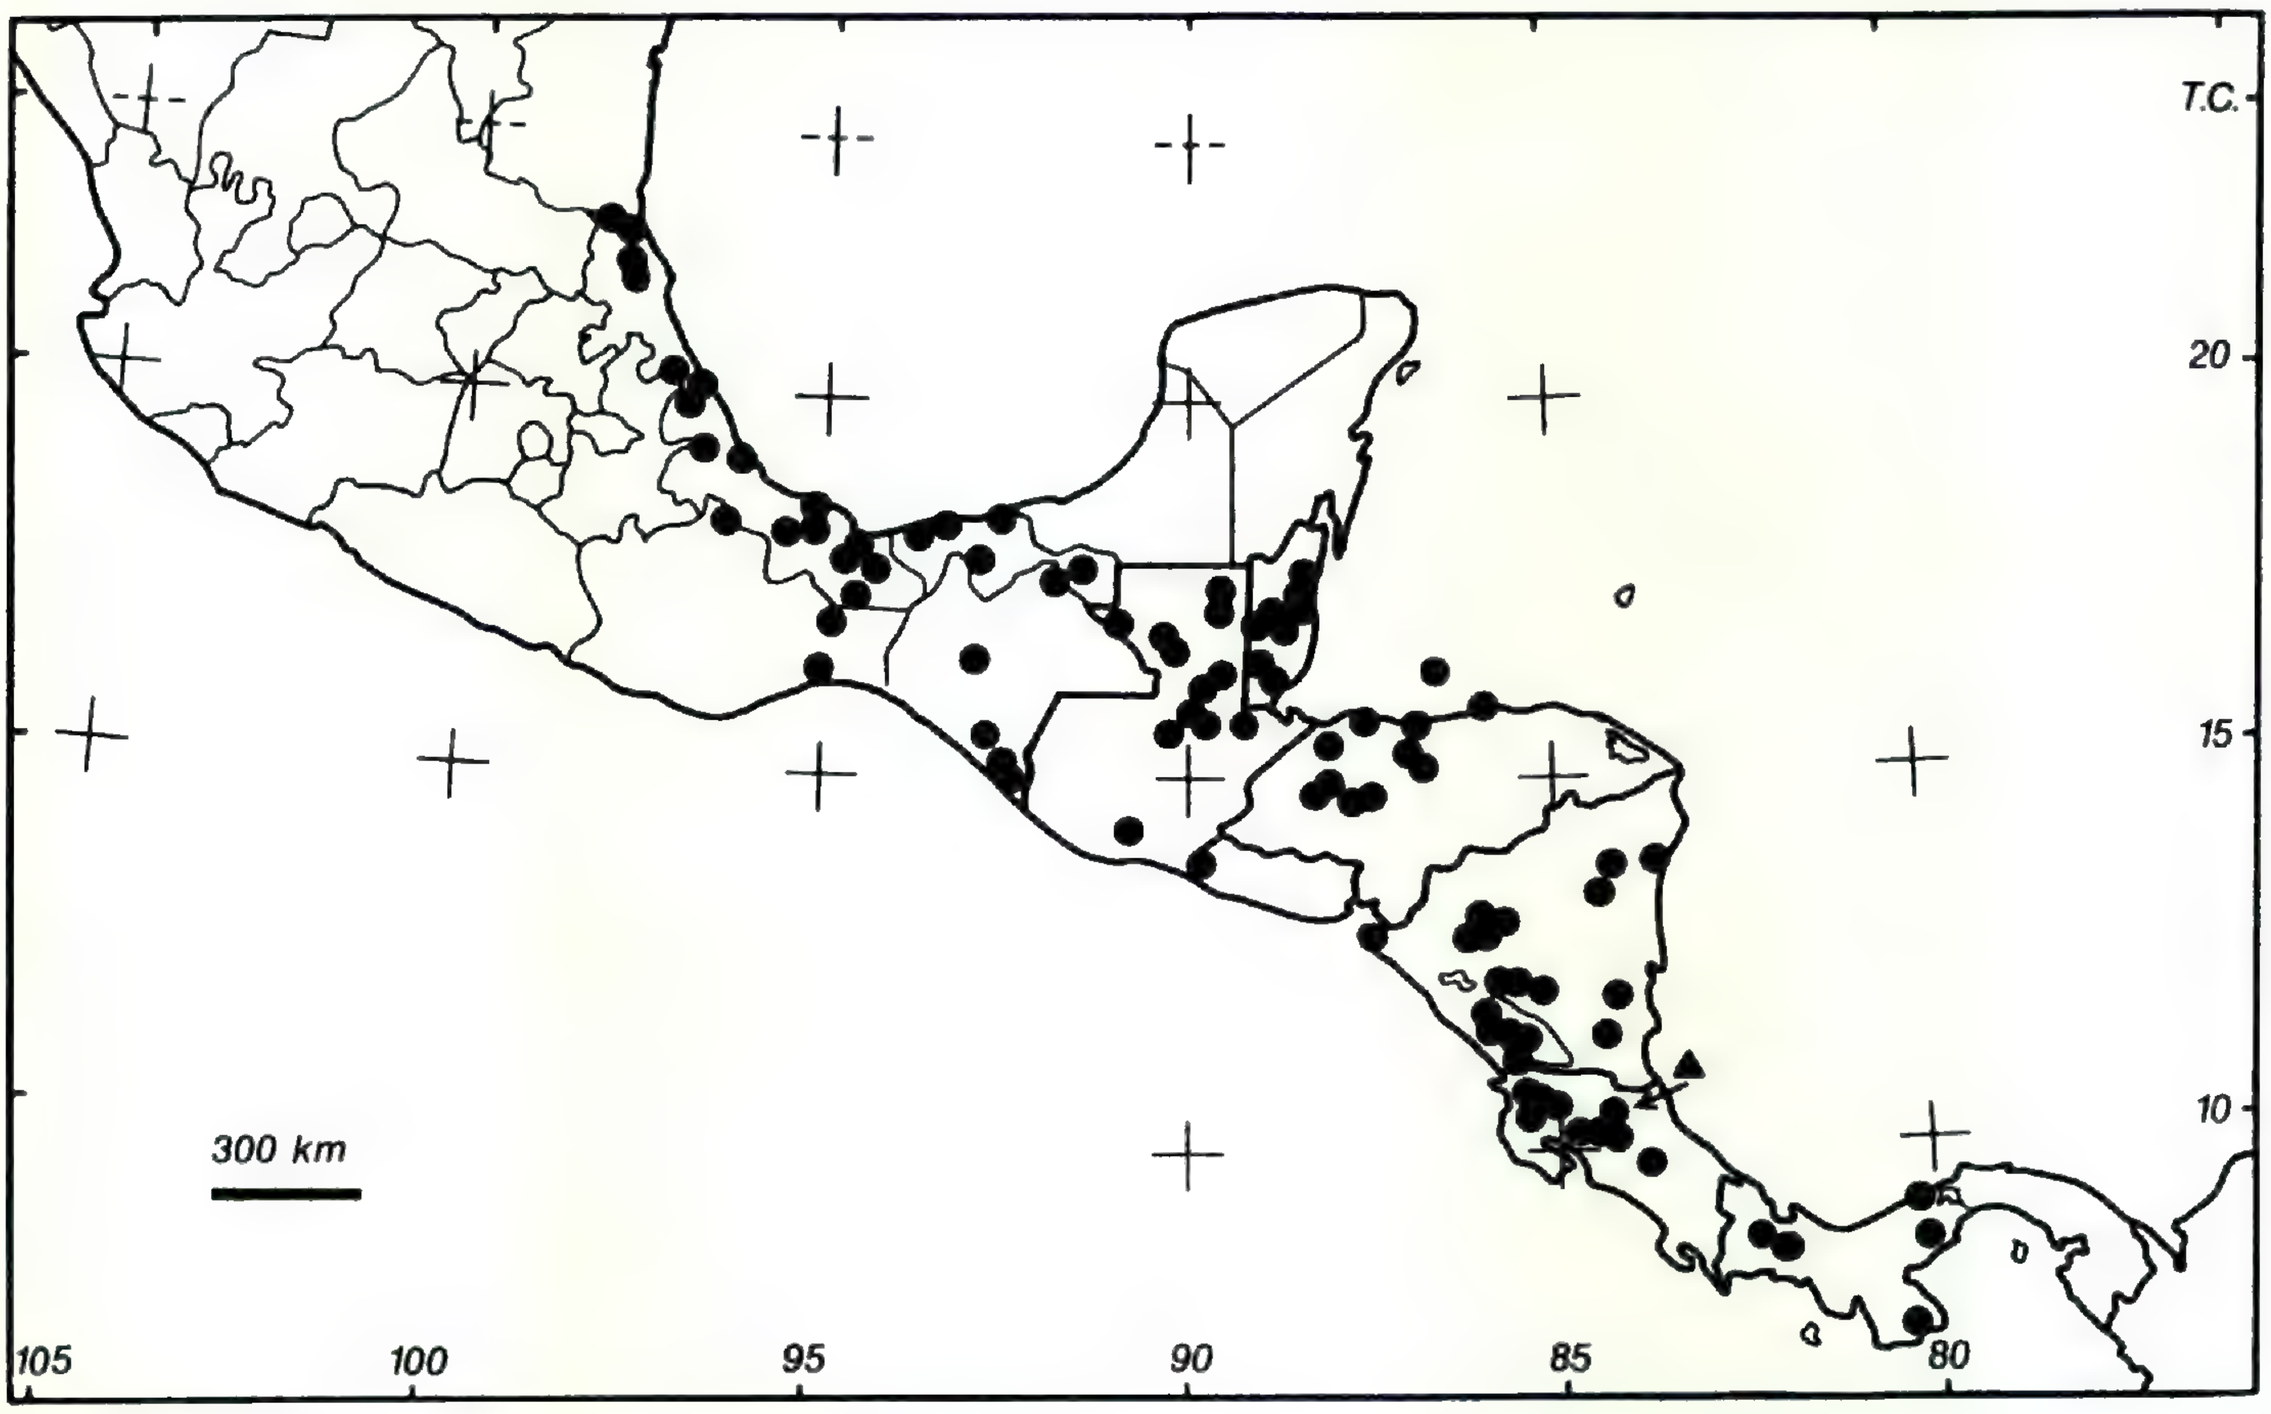

FIGURE 15. Distributions of *Psychotria lamarinensis* (triangle) and *P. quinqueradiata* (circles) in Mesoamerica.

juela: E of Río San Rafael, W of La Marina, 10°23′N, 84°23′W, 500 m, 19 May 1968 (fl), *Burger & Stolze 5062* (holotype, NY; isotype, MO). Figure 15.

Shrub 1.8–2 m tall; young stems glabrous, the bark pale, smooth; stipules ovate, 12 × 8 mm, glabrous, caducous, leaving a pale ridge with thick red-brown fringe. *Leaves* petiolate; petioles 5–7 mm long, glabrous, terete; blades membranous, elliptic, the apex acuminate, the base attenuate to attenuate-truncate, (13–)16–20 × (5–)7.5–9.5 cm, glabrous above and below, drying green-brown above, red-brown below; secondary veins 9–11 pairs, diverging 70°–85°, eucamptodromous, constantly arcuate, elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate. *Inflorescences* terminal, condensed globose panicles of cymes; panicle branched to 3 degrees; main axis 1.5–2 cm long, the peduncle lacking; secondary axes in 2–3 ranks, the first-rank axes 4, subequal, 0.5–1.5 cm long, the second-rank axes 4, subequal, 0.4–0.7 cm long, the third-rank axes 4, subequal, 0.2 cm long; cymes branched to 1–2 degrees; bracts triangular, 2 mm long, glabrous; bracteoles not evident. *Flowers* pedicellate, the pedicels 0.5–1.5 mm long; calyx cup-shaped, 0.5 mm long, the lobes not evident to barely evident, glabrous; corolla white, the tube cylindrical, 3 × 1 mm, white pubescent in throat, the lobes 5, linear with 1.5 mm linear extension from near apex, 2 × 1 mm; stamens 5, the filaments not seen in pins, 3.5–4 mm long in thrums, the anthers 0.7 mm long; style not seen in pins, 2–2.5 mm long in thrums, the branches linear. *Fruit* not seen.

Distribution (Fig. 15). Known only from the type locality near La Marina, Alajuela, Costa Rica, at ca. 500 m elevation in a region of tropical wet to premontane wet forest with equatorial-mountainous climate. It was collected in flower on May 19.

Additional specimen examined. COSTA RICA. ALAJUELA: E of Río San Rafael, W of La Marina, 10°23′N, 84°23′W, 500 m, 19 May 1968 (fl), *Burger & Stolze 5069* (MO, NY).

Psychotria lamarinensis may be recognized by its large, broad-elliptic leaves with the base narrowly subcordate, reduced globose inflorescence drying red-brown, and broad-ovate stipules. *Psychotria lamarinensis* may be a local derivative from *P. quinqueradiata*, from which the former differs in having much larger leaves with secondary veins diverging 70°–85° instead of 45°–60° and shorter (3 mm vs. 4–5 mm) corolla tubes.

Only a short-style flower morph has been seen, but only two flowering collections do not suffice to suggest that the species is thrum-monomorphic.

4. Psychotria micrantha Kunth in Humboldt, Bonpland and Kunth, Nov. Gen. Sp. 3: 363, pl. 284. 1819. *Uragoga micrantha* (Kunth) Kuntze, Revis. Gen. Pl. 2: 961. 1891. *Mapouria micrantha* (Kunth) Wernham, Kew Bull. 1914: 69. 1914. TYPE: Peru(?) (fl), *Bonpland s.n.* (holotype, P, n.v., fragment, F). Figure 14.

Psychotria rufescens Roemer & Schultes, Syst. Veg. 5: 192. 1819, non Kunth in H.B.K. (which is a synonym of *P. nervosa* Sw.), Nov. Gen. Sp. 3 (fasc. 12): 364. 1819. TYPE of *P. rufescens* Roem. & Schultes: Colombia. Río Magdalena, *Humboldt s.n.* (holotype, B—*Willdenow 4107*).

Tree 1.5–5(–8) m tall; young stems densely ferrugineous-pubescent, the bark slightly furrowed longitudinally; stipules sheathing, ovate, the apex biacuminate, 13–18(–22) × (5–)6–7(–8) mm, ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1–2.2 cm long, ferrugineous, grooved above; blades membranous, elliptic, the apex acuminate, the base cuneate to attenuate, (12–)20–32 × (5–)8–13 cm, puberulent above, the veins ferrugineous-pubescent, ferrugineous-pubescent below, drying green-brown to red-brown; secondary veins (18–)20–26 pairs, diverging (60°–)65°–70°, eucamptodromous to sometimes brochidodromous, constantly arcuate or straight then arcuate near margin, elevated below, ferrugineous, the axils lacking domatia or hairs; tertiary veins evident to conspicuous, percurrent, the quaternaries orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules; panicle branched to 4 degrees; main axis 10.5–17 cm long, the peduncle 6–8.5 cm long; secondary axes in 3–4 ranks, the first-rank axes 4 or 6, the long pair 2.5–5.5 cm long, the medium pair 1–2.5 cm long, the short pair 0–0.5 cm long, the second-rank axes 4 or 6, the long pair 0.5–2 cm long, the medium pair 0.2–0.8 cm long, the short pair 0–0.2 cm long, the third-rank axes 4, the longer pair 0.4–0.8 cm long, the shorter pair 0–0.4 cm long, the fourth-rank axes 4, the longer pair 0.4 cm long, the shorter pair 0.1 cm long; bracts ovate-acuminate, to 6 mm long, ferrugineous-pubescent. *Flowers* sessile; calyx cup-shaped, the tube 0.2–0.5 mm long, the lobes 5, barely evident to triangular, to 0.3 mm long, white pubescent without; corolla white, the tube cylindrical, 2 × 1 mm, short white pubescent in throat, the lobes 5, ovate, 1–1.5 × 1 mm; stamens 5, the filaments 1.5 mm long in pins, 3 mm long in thrums, the anthers 1 mm long; style 3.5–4 mm long in pins, 2–2.5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal, 4 mm long, 2.5–3(–3.5) mm diam., maturing red, drying black or sometimes red-brown, sparsely ferrugineous; persistent calyx a tube ca. 0.5 mm long, drying pale brown; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 14). Guatemala and Nicaragua through Panama, mostly on the Caribbean side, at elevations of 0–600 m in usually tropical moist to wet forest with equatorial to sometimes tropical-equatorial climate. It occurs also in Colombia, Venezuela, Ecuador, Peru, and Bolivia. *Psychotria micrantha* has been collected in flower April–September, December, and January, and in fruit July–March, primarily September–December.

VERAGUAS: Río de Jesús, Río Trinidad, 3 Aug. 1961 (fl), *Dwyer 1319* (GH).

Psychotria micrantha may be recognized by its densely ferrugineous vesture, large (20–32 × 8–13 cm) elliptic leaves with many (20–26) secondary veins and conspicuous percurrent tertiary veins, large panicles of glomerules, and small (4 × 2.5–3 mm) pubescent ellipsoid fruits.

5. Psychotria neillii C. Hamilton & Dwyer in C. Hamilton, Phytologia 64: 231. 1988. TYPE: Nicaragua. Río San Juan: Río Sábalo, 2 km al O de Sta. Eduviges, 11°03′N, 84°29′W, 80 m, 18 Feb. 1984 (fl, fr), *P. P. Moreno 23060* (holotype, MO). Figure 14.

Shrub or small tree, 1–4 m tall; young stems ferrugineous-pubescent, the bark smooth; stipules sheathing, lanceolate, the apex biacuminate, 10–14 × 3–5 mm, ferrugineous-pubescent, ciliate, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 4–8 mm long, ferrugineous-pubescent, terete; blades membranous, oblanceolate, the apex acuminate, the base cordate, 10–18 × 4–7.5 cm, glabrous above, the midvein basally ferrugineous-pubescent, sparsely ferrugineous-pubescent below, drying green-brown to red-brown; secondary veins 12–15 pairs, diverging (60°–)65°–75°, brochidodromous, constantly arcuate, elevated below, ferrugineous-pubescent below, the axils lacking domatia or hairs; tertiary veins evident to conspicuous, percurrent, the quaternaries orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3–4 degrees, the axes delicate; main axis (6–)9–15 cm long, the peduncle (3.5–)6–8 cm long; secondary axes in 3 ranks, the first-rank axes 4, the longer pair (1.5–)3–6 cm long, the shorter pair (0.8–)1–3.5 cm long, the second-rank axes 2 or 4, the longer pair (0.8–)1.4–3.2 cm long, the shorter pair ca. 1.5 cm long, the third-rank axes 2, 0.6–1.4 cm long; cymes branched to 2–3 degrees; bracts triangular, 4 mm long, ferrugineous-pubescent; bracteoles linear, 0.5 mm long, ferrugineous-pubescent. *Flowers* sessile to pedicellate, the pedicels to 1 mm long; calyx cup-shaped, the tube 0.3 mm long, the lobes 5, triangular, 0.2 mm long, ferrugineous-pubescent; corolla cream, the tube cylindrical, 1.5–2 × 1 mm, white pubescent in throat, red-brown pubescent without, the lobes 5, triangular, 1 × 0.8 mm; stamens 5, the filaments not seen in pins, 2.5 mm long in thrums, the anthers 0.8 mm long; style not seen in pins, 2 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal to obovoid, 5–7 mm long, 3–3.5 mm diam., maturing red, drying dark red-brown, sometimes puberulent; persistent calyx inconspicuous or a minute beak; seed dorsal surface with 3 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 14). Known from Caribbean coastal Costa Rica and just north into Nicaragua, at 80–400 m elevation in tropical moist to wet forest with equatorial climate. It has been collected in flower in January, February, and April and in fruit in February and May.

Additional specimens examined. NICARAGUA. RÍO SAN JUAN: nr. Caño Chontaleño, 20 km NE of El Castillo, 200 m, 18–21 Apr. 1978 (fl), *Neill & Vincelli 3503* (MO). COSTA RICA. HEREDIA: Magsasay, entre el campamento Canta Rana y Río Peje, 400 m, 14 Jan. 1983 (fl), *Chacón 76* (MO). LIMÓN: 7 km SW of Bribrí, 100–250 m, 4 May 1983 (early fr), *L. D. Gómez et al. 20357* (MO—2 sheets).

Psychotria neillii may be recognized by its great resemblance to *P. micrantha* and its delicate ferrugineous-pubescent inflorescence axes. *Psychotria neillii* differs from *P. micrantha* in having smaller (10–18 vs. 20–32 cm long) mature leaves with fewer (12–15 vs. 20–26) secondary veins, delicate inflorescence axes, and larger (5–7 mm vs. 4 mm long) fruit.

All three flowering collections are thrums; additional collections are necessary to determine whether the species is distylous or thrum-monomorphic.

6. Psychotria quinqueradiata Polakowsky, Linnaea 41: 570. 1877. *Uragoga quinqueradiata* (Polak.) Kuntze, Revis. Gen. Pl. 2: 962. 1891. TYPE: Costa Rica: prope San José et in silvis primaevis Carpinterae, June–Aug. (fl), *Polakowsky 135* (lectotype, B, destroyed, photos, GH, US). Figures 7g, 15.

Mapouria obovata Oersted, Amér. Centr. 17, t. 14, figs. 3, 4. 1863. *Psychotria obovata* (Oersted) Hemsley, Biol. Cent.-Amer. Bot. 2: 50. 1881, *non Psychotria obovata* Ruiz & Pavón, Fl. Peruv. Prodr. 2: 58. 1799. *Uragoga oerstedtiana* Kuntze, Revis. Gen. Pl. 2: 957. 1891. *Psychotria oerstediana* (Kuntze)

Standley, Contr. U.S. Natl. Herb. 23: 1390. 1926. TYPE: Mexico: *Liebmann s.n.* (holotype, C, n.v.).

Psychotria morae Polakowsky, Linnaea 41: 570. 1877. *Uragoga morae* (Polak.) Kuntze, Revis. Gen. Pl. 2: 961. 1891. TYPE: Costa Rica: San José, June 1875 (fl), *Polakowsky 171* (holotype, B, destroyed, photos, GH, US).

Shrub 0.5–2(–5) m tall; young stems glabrous, the bark pale, irregular; stipules sheathing, ovate-acuminate, 4–6 × 2–5 or 10–15 × 8 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.3–1 cm long, glabrous, grooved above; blades membranous to subcoriaceous, obovate to oblanceolate or medium- to broad-elliptic, the apex acute to short (–long)-acuminate, the base narrow-subcordate or attenuate, the margin sometimes crenate, (6–)9–15(–16) × (2–)3–7.5 cm, glabrous above and below, drying red-brown to green-brown, paler below; secondary veins 6–9(–10) pairs, diverging 45°–60°, eucamptodromous to usually brochidodromous, the secondary loops usually far from margin, increasingly arcuate toward margin, prominulous below, glabrous, the axils with domatia sometimes with tufts of hairs below; tertiary veins evident, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes (Fig. 7g), sometimes reduced to appear as fascicles of flowers behind terminal stipule; panicle branched to (2–)3 degrees; main axis 0.5–3.5 cm long, the peduncle lacking or rarely present, ca. 1.5 mm long; secondary axes in (1–)2(–3) ranks, the first-rank axes 4, subequal to equal, 0.5–3.5 cm long, the second-rank axes 4, subequal, 0.1–0.6 cm long, the third-rank axes 4, equal, 0.1–0.2 cm long; cymes branched to 1–2 degrees; bracts and bracteoles not evident. *Flowers* pedicellate, the pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes not evident or 5, barely evident, glabrous; corolla white, the tube cylindrical, 4–5 × 1–1.5 mm, white pubescent in throat, the lobes 5, lanceolate, 1.5–2 × 1 mm; stamens 5, the filaments 3–3.5 mm long in pins, 5.5–6.5 mm long in thrums, the anthers 1–1.5 mm long; style 5.5–7.5 mm long in pins, 4–5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal, 5.5–7 mm long, 4–5.5 mm diam., maturing red, drying red-brown; persistent calyx inconspicuous; seeds 2, the dorsal surface with 4–5 longitudinal furrows, the ventral surface with 2 sometimes shallow longitudinal furrows.

Distribution (Fig. 15). Widespread fom Veracruz, Mexico, through western Panama, at 0–1,300 m elevation in tropical moist to premontane wet forest with equatorial to tropical climate. This species has been collected in flower throughout the year, primarily January–June, and in fruit throughout the year.

Psychotria quinqueradiata and *P. morae* were published simultaneously by Polakowsky and serve as the only instance known to me where pin and thrum morphs of the same species were named as different species. I chose to retain the former ep-

ithet for its reference to the five equal axes radiating from the base of the inflorescence, an important recognition character (Fig. 7g).

The glabrous, obovate leaves drying red-brown to green-brown, with secondary veins usually brochidodromous making loops far from the margin, also aid in recognition. *Psychotria quinqueradiata* resembles *P. carthagenensis* in most vegetative and fruit characters but differs in its distinctive inflorescence and brochidodromous venation.

Stipule shape is invariable in the range of the species, but size varies greatly, from the typical 4–6 × 2–3 mm in Nicaragua and Costa Rica to 4–6 × 5 mm in Panama to 10–15 × 8 mm in Guatemala.

7. Psychotria viridis Ruiz & Pavón, Fl. Peruv. Prodr. 2: 61, pl. 210, fig. b. 1799. *Uragoga viridis* (Ruiz & Pavón) Kuntze, Revis. Gen. Pl. 2: 963. 1891. TYPE: n.v. Figures 4c, 7k, 13.

Psychotria microdesmia Oersted, Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 36. 1853. *Uragoga microdesmia* (Oersted) Kuntze, Revis. Gen. Pl. 2: 961. 1891. TYPE: Costa Rica: Jaris, 900 m, *Oersted 11610* (holotype, C, n.v., photo, F neg. 22840; isotypes, K, US).

Psychotria trispicata Grisebach, Pl. Wright., Pars II: 509. 1862 (cf. also Mem. Amer. Acad. Arts, n.s. 8: 508. 1863). *Uragoga trispicata* (Griseb.) Kuntze, Revis. Gen. Pl. 2: 963. 1891. TYPE: Cuba: San Andres, 1860–1864 (fr), *Wright 1280* (lectotype, NY; isolectotype, NY).

Tree 2–4 m tall; young stems glabrous, the bark pale, smooth; stipules ovate, the apex often acuminate, darker in central triangle, 8–15 × 3–6 mm, irregularly fringed, caducous, leaving a pale ridge with long red-brown fringe. *Leaves* subsessile to petiolate; petioles to 8 mm long, glabrous, flat above; blades membranous, elliptic-obovate, the apex short-acuminate to acute, the base attenuate, (6.5–)9–15 × (3–)4–5(–6) cm, glabrous above and below, drying dull red-brown to green-brown; secondary veins 7–10 pairs, diverging 45°–55°, eucamptodromous, straight then arcuate ⅔ to margin, elevated below, glabrous, the axils often with domatia below especially near apex (Fig. 4c); tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules (Fig. 7k); panicle branched to 3 degrees; main axis 6.5–12 cm long, the peduncle 2–6 cm long; secondary axes in (4–)5 ranks, the first-rank axes 4, the longer pair (0.6–)1–2.5 cm long, the shorter pair usually reduced or to 0.3 cm long, the second-rank axes 2 or 4, reduced and thus flowers disposed in glomerules along main axis, the longer pair when present 0.5–0.8 cm long, the third-rank axes 2 or rarely 4, reduced, the longer pair when present 0.4 cm long, the fourth-rank axes 2, reduced, the fifth-rank axes 2, reduced; tertiary axes reduced and thus flowers disposed in glomerules along secondary axes; bracts and bracteoles irregular, to 1 mm long, red-brown ciliate. *Flowers* sessile; calyx cup-shaped, ca. 0.5 mm long, the lobes not evident or rarely 5, triangular, to 0.2 mm long, glabrous; corolla white, the tube cylindrical, 1.5 × 1 mm, thick white pubescent in throat, the lobes 5, lanceolate, 1 × 0.6 mm; stamens 5, the filaments 2 mm long, the anthers 0.5 mm long; style 2.5 mm long, the branches clublike. *Fruit* when dry ellipsoidal, 4.5–5 mm long, 3–3.5 mm diam., maturing red, drying red-brown; persistent calyx a beak to 0.5 mm long; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 13). Very sparse distribution throughout Central America at 0–1,000 m elevation, collected most commonly in the lowlands of eastern Panama, in tropical moist to premontane wet forest with equatorial to tropical climate. *Psychotria viridis* occurs also in Cuba, Hispaniola, Colombia, Venezuela, Ecuador, Peru (where it is extremely common), Brazil, and Bolivia. In Central America it has been collected in flower September–March and in fruit January–June and in September.

Río Tortí, 8°52′N, 78°22′W, 150 m, 15 Jan. 1983 (fr), *Stein 1337* (MO).

Psychotria viridis may be readily recognized by its inflorescence: all ranks of secondary axes except the first and second are reduced so that flowers and fruit appear in clusters along the main axis (Fig. 7k). *Psychotria viridis* is, in its vegetative and fruit characters, almost identical to *P. carthagenensis*; the distinctive inflorescence may be viewed as a reduction in secondary and tertiary axes of that of *P. carthagenensis*.

There appears to be only one flower morph, a homostyle, in Central American *P. viridis*, with no spatial separation between the exserted anthers and stigma. Leaves in Guatemala and Belize have fewer secondary veins than elsewhere in Central America.

GROUP 2. THE *COSTIVENIA* GROUP

Shrub or tree; young stems glabrous or puberulent or rarely tomentose or ferrugineous-pubescent; stipules usually not sheathing, ovate, uniform in color or often with a pale central triangle or keel (Fig. 2b), glabrous or puberulent or ferrugineous-pubescent or sometimes fringed, caducous or often persistent at terminal 2–6 nodes. *Leaf* blades elliptic or ovate or obovate or oblanceolate, *drying usually yellow-green or sometimes green*, green-brown, or red-brown, *often dull* or pale, sometimes chalky above, sometimes darker below; secondary veins (6–)7–19(–21) pairs, diverging (45°–)60°–85°, eucamptodromous or brochidodromous, the axils usually lacking domatia or hairs (except sometimes *P. horizontalis* and *P. sylvivaga*); tertiary veins orthogonal reticulate or less commonly percurrent, the intersecondaries often conspicuous, the tertiary loops sometimes evident (*P. fendleri* and *P. horizontalis*). *Inflorescences* panicles of cymes or rarely of glomerules (*P. flava*), pedunculate (except rarely in *P. horizontalis*); *secondary axes usually in 2 or 3 size-differentiated pairs per rank* (Fig. 7b) or sometimes 2 or rarely 4 subequal; bracts not conspicuously enlarged (to 5 mm long in *P. flava* and *P. pleuropoda*). *Corolla* tubes 2–3.5 mm long (4–5 mm in *P. papantlensis*), the lobes without apical extensions. *Fruit* when dry spherical to ellipsoidal (sometimes slightly obovoid in *P. flava*); *persistent calyx a beak or a tube* Fig. 9b) *or of linear lobes* (Fig. 9e) or not evident, over 1 mm long only in *P. fendleri* and *P. horizontalis*; dorsal seed surface with 3–5 regular (Fig. 10b) or 6–15 irregular longitudinal furrows (Fig. 10i, j), the ventral surface with 2 often incompletely divided longitudinal furrows (Fig. 10e) or one often T-shaped longitudinal furrow (*P. flava*; Fig. 10j) rarely plus 4 irregular longitudinal furrows (*P. sylvivaga*).

This subgroup may be subdivided into two species complexes. The *Psychotria horizontalis* complex includes the widespread *P. horizontalis* and *P. fendleri*, the latter endemic to Caribbean coastal Panama (Figs. 16, 17); they share the distinctive character states of immediately caducous stipules, brochidodromous secondary venation with connecting loops far from the blade margin plus evident tertiary connecting loops, and persistent calyx at least 1 mm long. The *P. costivenia* complex, which includes the remaining seven species, has in common often persistent stipules usually with a paler central triangle or keel, often conspicuous intersecondary veins, and persistent calyx a beak or tube no longer than 1 mm. Two species are widespread—*P. costivenia* (Mexico through Nicaragua; Fig. 18) and *P. grandis* (Guatemala through Panama; Fig. 19), both also in the Greater Antilles—and five have small ranges: *P. balancanensis* (Tabasco, Mexico; Fig. 19), *P. flava* (southern Mexico and Petén, Guatemala; Fig. 17), *P. papantlensis* (southern Mexico through Belize; Fig. 16), *P. pleuropoda* (southern Mexico through Belize; Fig. 17), and *P. sylvivaga* (central Costa Rica; Fig. 17).

Of the nine species in the group, six appear distylous; two of those, *Psychotria papantlensis* and *P. pleuropoda*, show some between-morph asymmetry in floral part lengths. Only one species, *P. fendleri*, apparently has evolved a derived state, thrum-monomorphy. Too few specimens of *P. balancanensis* have been seen to determine its breeding system.

8. Psychotria balancanensis C. Hamilton, Phytologia 64: 219. 1988. TYPE: Mexico. Tabasco: Balancán, La Palma, 1–6 June 1939

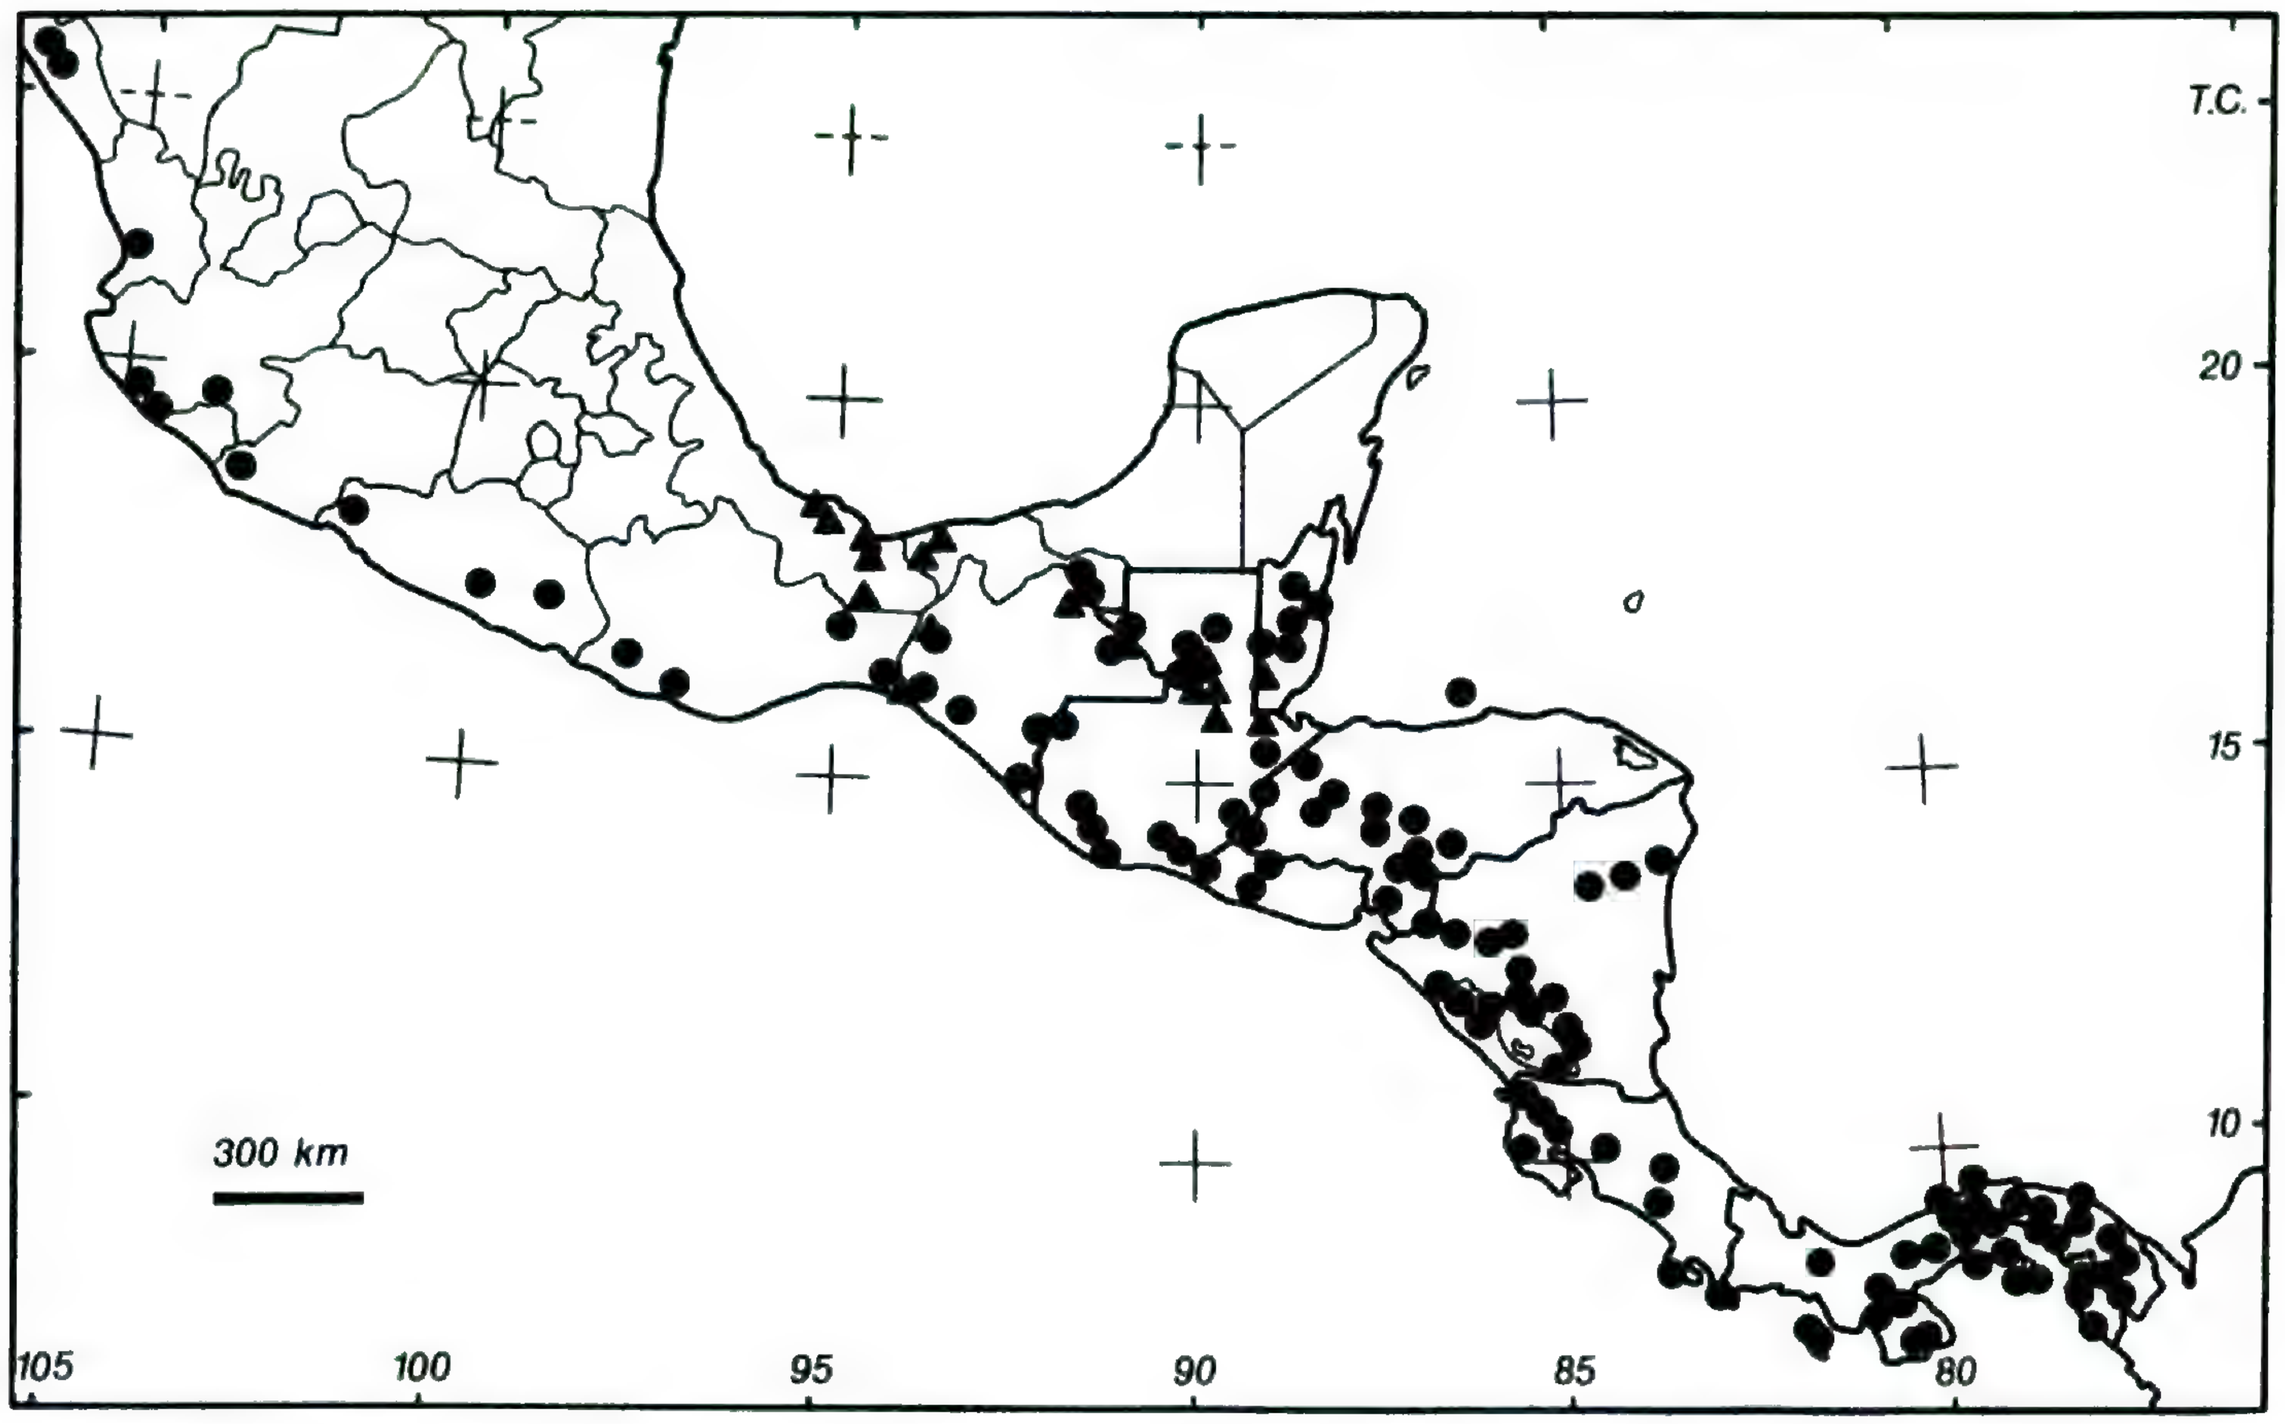

FIGURE 16. Distributions of *Psychotria horizontalis* (circles) and *P. papantlensis* (triangles) in Mesoamerica.

(fl), *Matuda 3286* (holotype, F; isotypes, A, MEXU, NY). Figure 19.

Shrub ca. 2.5 m tall; young stems glabrous, the bark smooth, sometimes with shallow fissures; stipules ovate-triangular, 6.5–7.5 × 3–4 mm, fringed, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.9–2 cm long, glabrous, flat above; blades membranous, elliptic to slightly obovate, the apex acuminate, the

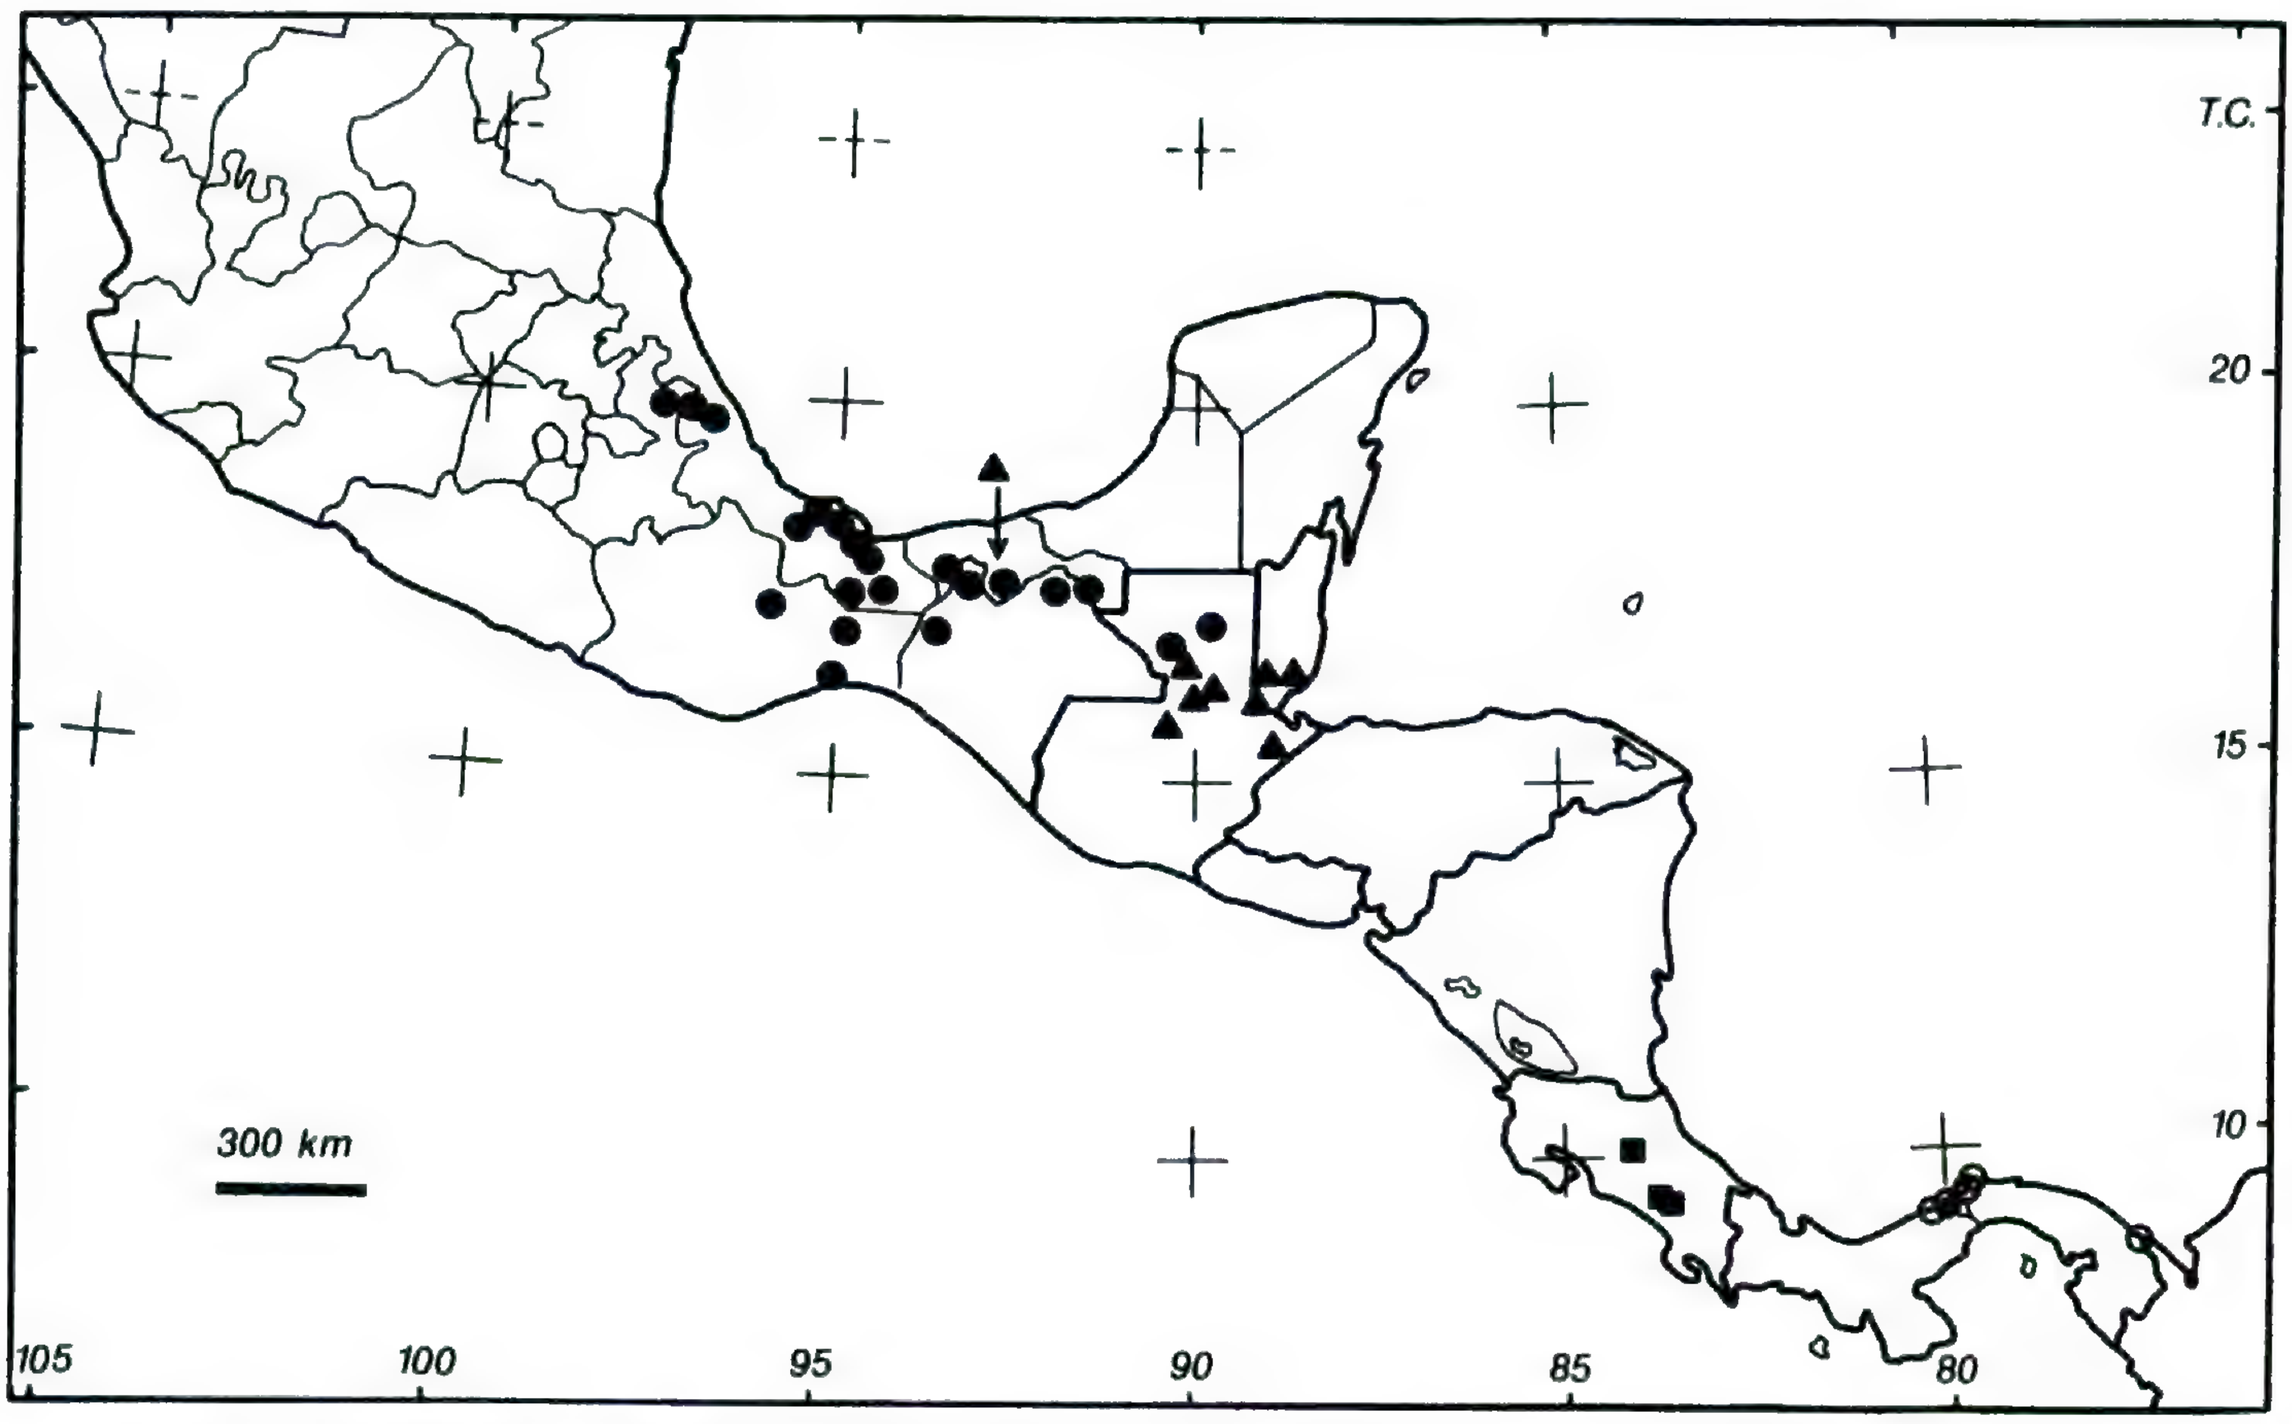

FIGURE 17. Distributions of *Psychotria fendleri* (open circles), *P. flava* (solid circles), *P. pleuropoda* (triangles), and *P. sylvivaga* (squares).

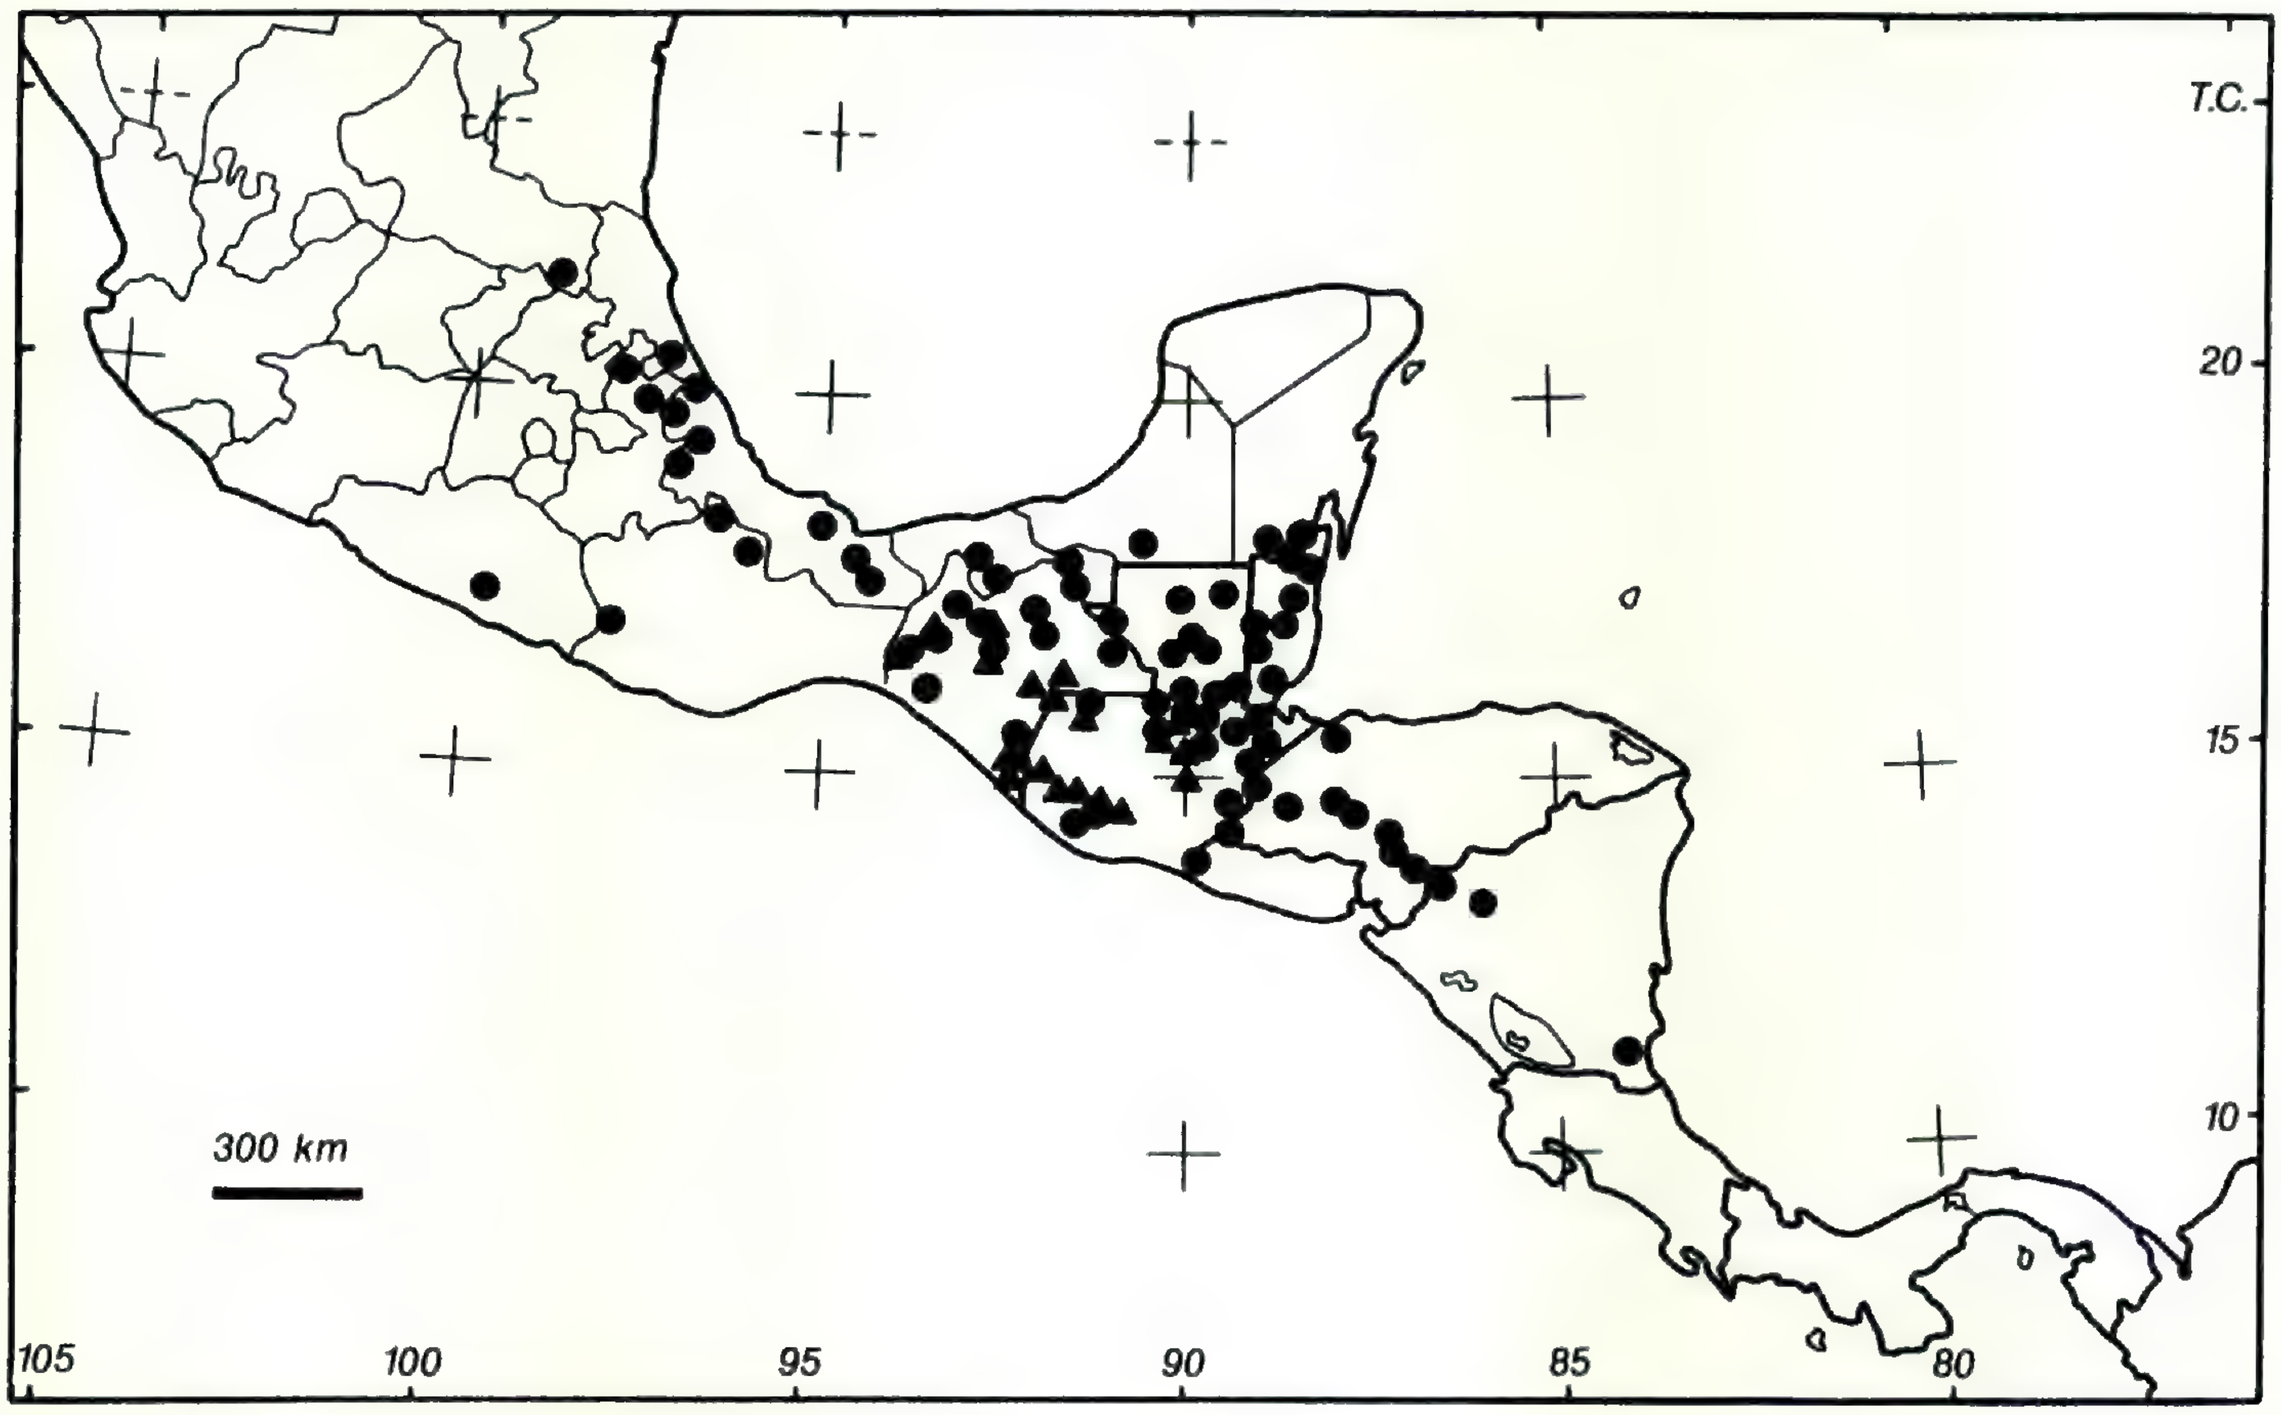

FIGURE 18. Distributions of *Psychotria costivenia* var. *altorum* (triangles) and *P. costivenia* var. *costivenia* (circles) in Mesoamerica.

base attenuate, (6–)7–11(–13) × (2–)3–6 cm, glabrous above and below, drying dull green; secondary veins 8–10 pairs, diverging 65°–75°, eucamptodromous to brochidodromous, constantly arcuate, elevated below, glabrous, the axils lacking domatia and hairs; tertiary veins evident, orthogonal reticulate to percurrent. *Inflorescences* terminal, panicles of cymes; panicle branched to 3–

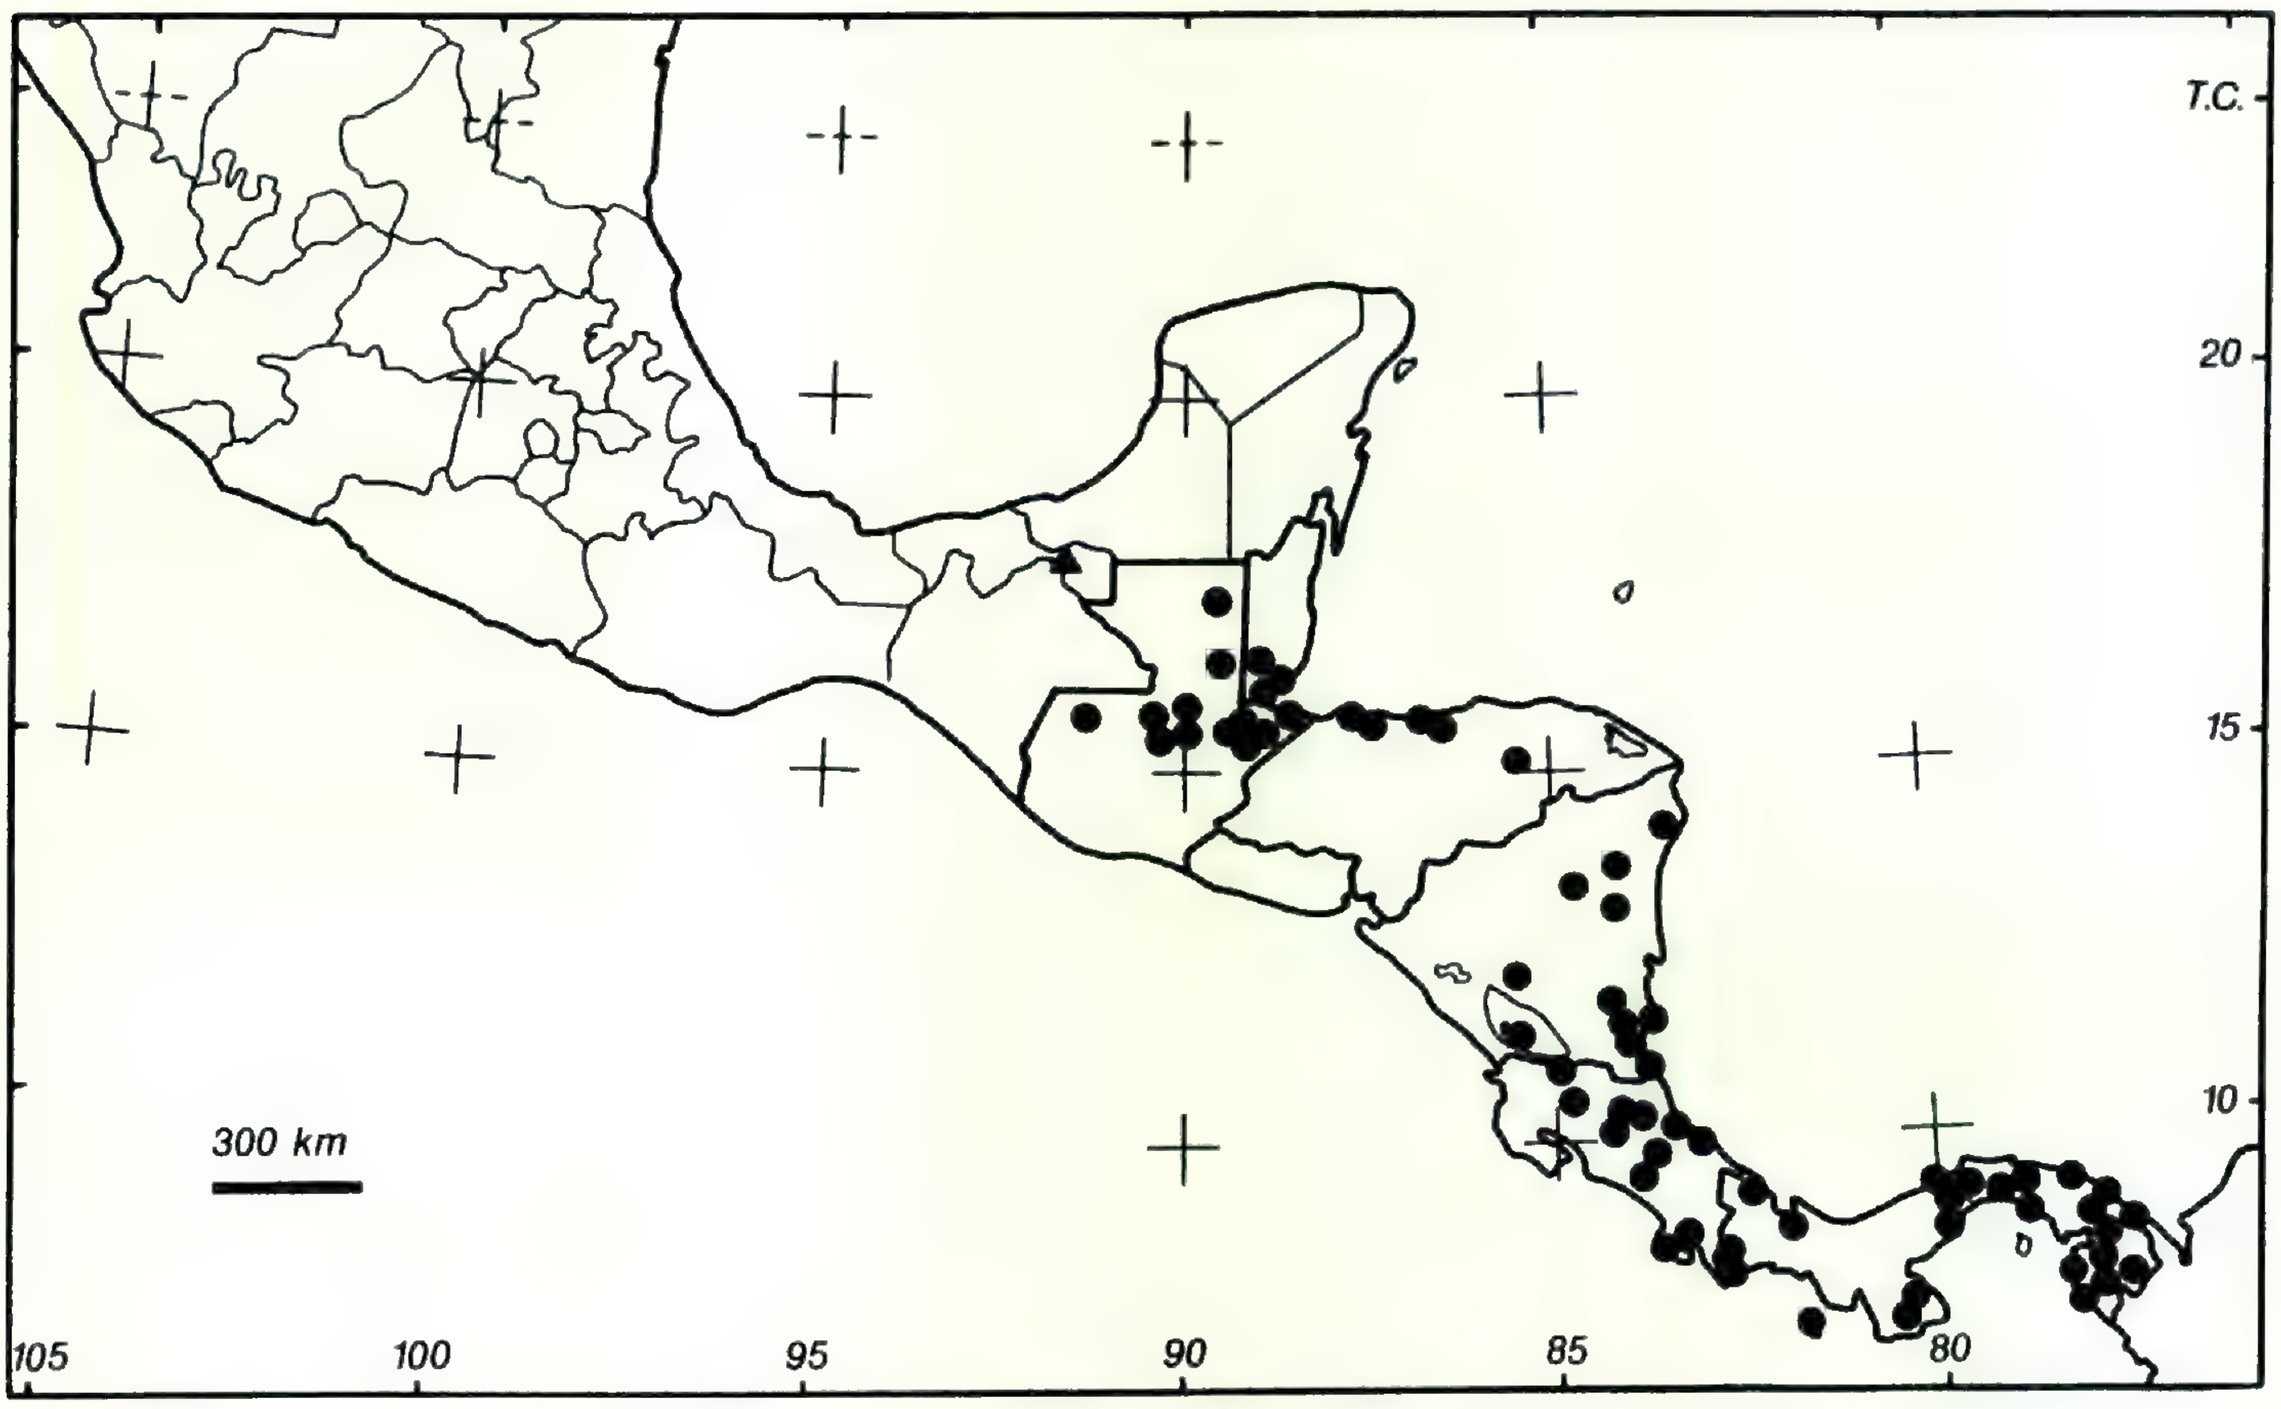

FIGURE 19. Distributions of *Psychotria balancanensis* (triangle) and *P. grandis* (circles) in Mesoamerica.

4 degrees; main axis 3.5–9 cm long, the peduncle 2.5–7 cm long; secondary axes in 2 ranks, the first-rank axes 2 or 4, the longer pair 0.8–1.2 cm long, the shorter pair 0.2–0.8 cm long, the second-rank axes 4, equal, 0.3–0.7 cm long; cymes branched to 1–2 degrees; bracts and bracteoles irregular triangular, 0.7 × 0.8 mm, puberulent, fringed. *Flowers* pedicellate; pedicels 0.7–1 mm long; calyx cup-shaped, the tube 0.3–0.5 mm, the lobes 5, broadly triangular to barely evident, 0.2–0.3 × 0.5 mm, fringed; corolla white, the tube cylindrical, 2.5–3 × 1.2 mm, white pubescent in throat, the lobes 5(–6), triangular, spreading, 1.5 × 1 mm; stamens 5(–6), the filaments 2.5–3 mm long in pins, not seen in thrums, the anthers 1 mm long; style 4.5 mm long in pins, not seen in thrums, the branches linear. *Fruit* not seen.

Distribution (Fig. 19). Known only from the type collection from eastern Balancán, Tabasco, in a region of evergreen forest and savanna with equatorial-tropical climate. It was collected in flower in early June.

Psychotria balancanensis may be recognized by its moderate-sized (7–11 cm long) broad-elliptic leaves drying dull green to green-brown with conspicuous intersecondary veins and by its inflorescence with the secondary axes in two ranks near the apex of the main axis. This species differs from *P. costivenia* in having broader-elliptic leaves and smaller inflorescences with fewer (two vs. four) ranks of secondary axes.

Only the pin morph has been collected, but the one flowering specimen seen is not sufficient to suggest that the species is pin-monomorphic.

9. Psychotria costivenia Grisebach, Pl. Wright., Pars II: 508. 1862. (Cf. also Mem. Amer. Acad. Arts, n.s. 8: 508. 1863.) *Uragoga costivenia* (Griseb.) Kuntze, Revis. Gen. Pl. 2: 960. 1891. TYPE: Cuba. Oriente: prope villam Monte Verde dictam, Jan.–July 1859 (fr), *Wright 242* (lectotype designated herein, GH). Figures 2b, 10e, 18.

Shrub 0.5–5(–6) m tall; young stems glabrous to red-brown puberulent to sparsely tomentose, the bark often pale, smooth; stipules ovate, the apex cuspidate or aristate or biaristate, 6–10(–11) × 3–7(–10) mm, with pale center and often evident central keel (Fig. 2b), glabrous to red-brown subtomentose, often fringed especially near apex, caducous, sometimes persistent at the terminal 2–3 nodes, leaving a pale ridge with red-brown fringe. *Leaves* sessile to petiolate; petioles to 1.5(–2) cm long, glabrous to puberulent, flat and sometimes shallowly grooved above; blades membranous to rarely subcoriaceous, elliptic or rarely obovate, the apex acute to acuminate, the base attenuate, (4–)4.5–17(–22) × (1–)1.5–6(–8) cm, glabrous above and below, drying green, yellow-green, red-brown, or green-brown; secondary veins 7–12 (–18) pairs, diverging 65°–80°, eucamptodromous to brochidodromous, straight or constantly arcuate, elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate, the intersecondaries particularly conspicuous. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3–4 degrees; main axis 3.5–22 cm long, the peduncle (0.7–)2.5–11.5 cm long; secondary axes in (2–)3–4(–5) ranks, the first-rank axes 2 or 4, the longer pair 0.5–4.7 cm long, the shorter pair 0.3–2.3 cm long, the second-rank axes 2 or 4, the longer pair 0.3–2.5 cm long, the shorter pair 0.2–1.5 cm long, the third-rank axes 2 or 4, the longer pair 0.1–1.5 cm long, the shorter pair 0.1–0.5 cm long, the fourth-rank axes 2 or 4, the longer pair 0.1–0.8 cm long, the shorter pair 0.4 cm long, the fifth-rank axes 2, 0.1 cm long; cymes branched to 1–3 degrees; bracts linear, 2–5 mm long, puberulent, sometimes fringed; bracteoles irregular, to 1 mm long, red-brown pubescent. *Flowers* sessile or pedicellate, the pedicels to 1.5 mm long; calyx cup-shaped, the tube 0.3–0.7 mm long, the lobes 5, barely evident to triangular to linear, to 0.8 mm long, to 0.6 mm wide, fringed, often puberulent outside; corolla white, the tube cylindrical, 2–3.5 × 1–2 mm, white pubescent in throat, the lobes 5, linear, 1.5–2 × 0.7–1 mm; stamens 5, the filaments 2–3 mm long in pins, 3.5–5 mm long in thrums, the anthers 0.8–1 mm long; style (3–)3.5–5 mm long in pins, 2.5–3.5 mm long in thrums, the branches short, clublike. *Fruit* when dry spherical to ellipsoidal, 5–7(–8.5) mm long, 4–6(–7) mm diam., maturing red, drying red-brown or black; persistent calyx not evident or as a beak, drying green or red-brown; seed dorsal surface with 4–5 longitudinal furrows, the ventral surface with 2 deep longitudinal furrows, incompletely divided (Fig. 10e).

Distribution (Fig. 18). Mexico through Nicaragua at elevations of 20–2,800 m.

Psychotria costivenia may be recognized by its stipules usually persisting at the terminal two or three nodes and having a paler central triangle (Fig. 2b), its elliptic leaves drying usually green or yellow-green with secondary veins drying paler and intersecondaries particularly conspicuous, and its

inflorescence secondary axes in one or two unequal pairs per rank, the higher ranks decreasing in size fairly uniformly.

KEY TO VARIETIES OF *PSYCHOTRIA COSTIVENIA*

1a. Leaf blades generally 4.5–10 × 1.5–3 cm, drying red-brown or green brown; inflorescence main axis 3.5–6 cm long ..... 9a. *P. costivenia* var. *altorum*

1b. Leaf blades generally 8–17 × 3.5–6 cm, drying green or yellow-green; inflorescence main axis 5.5–22 cm long ..... 9b. *P. costivenia* var. *costivenia*

9a. Psychotria costivenia Grisebach var. **altorum** (Standley & Steyermark) C. Hamilton, Phytologia 64: 223. 1988. *Psychotria altorum* Standley & Steyerm., Publ. Field Mus. Nat. Hist., Bot. Ser. 23: 86. 1944. TYPE: Guatemala. Quezaltenango: Montaña Chicharro, on lower SE-facing slopes of Volcán Sta. María, 2–4 mi. S of Sta. María de Jesús, 1,400–1,500 m, 17 Jan. 1940 (fl), *Steyermark 34302* (holotype, F). Figure 18.

Shrub: stipules ovate, the apex aristate or biaristate, 4–4.5 × 3 mm, the extensions 1.5–3 mm long, caducous, never persistent at the terminal 2–3 nodes. *Leaves:* blades narrow-elliptic, (4–)4.5–10(–12) × (1–)1.5–3(–4) cm, drying red-brown or green-brown; secondary veins 7–9(–11) pairs. *Inflorescences* few-branched panicles of cymes; panicle branched to 3(–4) degrees; main axis 3.5–6 cm long, the peduncle (0.7–)2.5–4 cm long; secondary axes in 3–4(–5) ranks, the first-rank axes 2 (or 4), 0.5–1.6 cm long, the shorter pair 0.3–1 cm long, the second-rank axes 2 or 4, 0.3–0.8 cm long, the shorter pair 0.2–0.5 cm long, the third-rank axes 2 (or 4), 0.1–0.5 cm long, the shorter pair 0.2 cm long, the fourth-rank axes 2, 0.1–0.3 cm long, the fifth-rank axes 2, 0.1 cm long; cymes branched to 1–2 degrees. *Flowers:* calyx lobes triangular to linear, 0.3–0.8 mm long. *Fruit:* drying red-brown; persistent calyx not evident or sometimes as a beak, drying red-brown.

Distribution (Fig. 18). Chiapas, Mexico, and southern Guatemala mostly at elevations of 1,000–2,800 m in areas of pine–oak forest with tropical climate. It has been collected in flower January–June and once in November and in fruit mostly September–February and rarely in May and June.

Selected specimens examined. MEXICO. CHIAPAS: Chamula, Yal Ichin, 1,800 m, 3 Apr. 1965 (fl), *Breedlove 9537* (NY); Mpio. La Trinitaria, Lago Tsiskaw, 30 mi. Psychotria altorum has been reduced to a variety within *P. costivenia* because the distinguishing features (see varietal key) are not sufficient to distinguish a species, though varietal recognition is useful.

Leaf blades of this variety appear to have more secondary veins in Mexico than in Guatemala; persistent calyces are beaklike in Mexico and not evident in Guatemala.

9b. Psychotria costivenia Grisebach var. **costivenia.** Figure 18.

Mapouria miradorensis Oersted, Amér. Centr. 17, t. 14, fig. 9. 1863. *Psychotria miradorensis* (Oerst.) Hemsley, Biol. Cent.-Amer. Bot. 50. 1881. *Uragoga miradorensis* (Oerst.) Kuntze, Revis. Gen. Pl. 2: 961. 1891. TYPE: Mexico. Veracruz: Mirador, 900 m, 1841–1843 (fl), *Liebmann 11662* (lectotype, C, photo F neg. no. 22839; isolectotype, US).

Shrub: stipules ovate, the apex cuspidate, 6–10(–11) × 3.5–7(–10) mm, caducous, often persistent at the terminal 2–3 nodes. *Leaves:* blades elliptic or rarely obovate, (7–)8–17(–22) × (3–)3.5–6(–8) cm, drying green, yellow-green, or less often green-brown; secondary veins (8–)9–12(–18) pairs. *Inflorescences* many-branched panicles of cymes; panicle branched to 3–4 degrees, the axes often winged; main axis 5.5–22 cm long, the peduncle 2.5–11.5 cm long; secondary axes in (2–)4 ranks, the first-rank axes (2 or) 4, the longer pair (0.6–)1–4.7 cm long, the shorter pair (0.3–)0.5–2.3 cm long, the second-rank axes 2 or 4, the longer pair 0.5–2.5 cm long, the shorter pair 0.2–1.5 cm long, the third-rank axes 2 or 4, the longer pair (0.2–)0.4–1.5 cm long, the shorter pair 0.1–0.5 cm long, the fourth-rank axes 2 or 4, the longer pair 0.1–0.8 cm long, the shorter pair 0.4 cm long; cymes branched to 1–3 degrees. *Flowers:* calyx lobes barely evident to triangular, to 0.3 mm long. *Fruit:* drying black; persistent calyx not evident or often as a beak, to 1 mm long, drying green.

Distribution (Fig. 18). Widespread in Mexico through Nicaragua, at elevations of 20–1,500 m, usually at 1,000 m or lower, in evergreen to subevergreen forest with equatorial to tropical climate. It has been collected in flower January–June, principally March–May, and in fruit throughout the year.

Psychotria miradorensis, described from Mexico, is indistinguishable from *P. costivenia*, described from Cuba; the latter name was published only a few months prior to the former.

Leaf blades from Zelaya, Nicaragua, at the southern end of the geographical range, have 15–18 secondary veins, numbers rarely reached in the rest of the range. Inflorescences tend to be smaller in Honduras, El Salvador, and Nicaragua than farther north. The corolla appears generally wider (2 mm) in Honduras than in the rest of the range.

10. Psychotria fendleri Standley, Contr. U.S. Natl. Herb. 18: 129. 1916. TYPE: Panama. Canal Area: Chagres, Isthmus of Panama, 25 Feb. 1850 (fl), *Fendler 59* (holotype, US; isotypes, GH, MO). Figure 17.

Shrub 1–2 m tall; young stems glabrous to minute puberulent, the bark smooth to longitudinally striate; stipules ovate, 5–9 × 3–4 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* subsessile; petioles to 3 mm long, glabrous, flat and furrowed above; blades coriaceous, stiff, obovate, the apex acute to acuminate, the base attenuate, the margins inrolled, (5–)7–9(–10) × (3–)3.5–5(–5.5) cm, glabrous above and below, drying bright chalky yellow-green above, dull green below, often partly red-brown; secondary veins (6–)8–10 pairs, diverging 50°–70°, brochidodromous, straight, elevated below, glabrous, the secondary loops far from margin, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate, the tertiary loops between secondary loops and margin evident. *Inflorescences* terminal, panicles of cymes; panicle branched to 3(–4) degrees; main axis 5.5–9 cm

long, the peduncle 3–7 cm long; secondary axes in 2(–3) ranks, the first-rank axes (2 or) 4, the longer pair 0.5–1.5 cm long, the shorter pair 0.2–0.8 cm long, the second-rank axes 2 (or 4), subequal, 0.2–1 cm long, the third-rank axes 2, 0.2 cm long; cymes branched to 1–2 degrees; bracts broad, irregular, ca. 2 mm long, glabrous to puberulent; bracteoles triangular, 0.5 mm long, puberulent. *Flowers* pedicellate, the pedicels 1 mm long; calyx cup-shaped, the tube 1.5 mm long, the lobes 5, triangular, 0.5 × 0.7 mm, glabrous; corolla white, the tube cylindrical, 2.5 × 1.5 mm, white pubescent in throat, the lobes 5, 1.5 × 1 mm; stamens 5, the filaments not seen in pins, 3–4 mm long in thrums, the anthers 1 mm long; style not seen in pins, 2–2.5 mm long in thrums, the branches linear. *Fruit* when dry spherical to ellipsoidal, 4–4.5 mm long, 3–4 mm diam., maturing red, drying black; calyx persistent, to 1.5 mm long, drying green; seed dorsal surface with 4 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 17). Known from the Caribbean coast of Panama, just east and west of the Canal, collected near sea level in tropical moist to tropical wet forest with equatorial-tropical climate. It has been collected in flower February, April, May, and August; fruiting specimens date from April and August.

Additional specimens examined. PANAMA. CANAL AREA: Fort Sherman, from Piña to 3 mi. NE of Piña, 2 Apr. 1973 (fl), *Liesner 1386* (F, MO). COLÓN: Miguel de la Borda, along steep clay sea coast, 24 Apr. 1970 (fl, fr), *Croat 10023* (F, MO, NY); Isla Grande, 11 Apr. 1970 (fl), *D'Arcy 4020* (MO); María Chiquita, nr. beach, 10 Aug. 1967 (fl, fr), *Dwyer & Kirkbride 7783* (MO—3 sheets, NY); 4.5 km SW of Piña, Qda. Sta. Marta, 0–5 m, 17 May 1974 (fl), *Nee 11682* (MO); *Nee 11688* (MO). SAN BLAS: between Puerto Obaldía and Puerto Armila, coastal rocks, 0–100 m, 29 Apr. 1980 (fl), *D'Arcy 13676* (MO).

Psychotria fendleri may be recognized by its coriaceous, moderate-sized (7–9 cm long) leaves usually drying chalky yellow-green and with brochidodromous secondary venation suggestive of that of *P. horizontalis*. *Psychotria fendleri* is distinguished from *P. horizontalis*, from which it may be a localized derivative, by its coriaceous leaves and chalky color when dry.

The eight flowering specimens examined are all thrums, suggesting that the species is thrum-monomorphic.

11. Psychotria flava Oersted ex Standley, J. Wash. Acad. Sci. 17: 341. 1927. TYPE: Mexico. Veracruz: Misantla (fl), *Liebmann 11605* (holotype, C, n.v., photo, F neg. no. 22830). Figures 7b, 10j, 17.

Shrub or small tree, 2–10 m tall; young stems glabrous to puberulent, the bark pale, smooth; stipules ovate, the apex biaristate, 7–22 × 4–8 mm, the extensions 3–5 mm long, puberulent, fringed, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1.5–3.5 cm long, glabrous, grooved above; blades membranous, elliptic, the apex acute to acuminate, the base attenuate, 16–40 × 6–13 cm, glabrous above, puberulent to sometimes glabrous below, drying chalky yellow-green to green-brown above, darker green-brown below; secondary veins 14–21 pairs, diverging 60°–70°, eucamptodromous to brochidodromous, straight to constantly arcuate, elevated below, puberulent or sometimes glabrous below, the axils lacking domatia or hairs; tertiary veins evident to conspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules (Fig. 7b); panicle branched to 4 degrees; main axis (9–)13–26 cm long, the peduncle (5–)7–15 cm long; secondary axes in (3–)4 ranks, the first-rank axes 4 or 6, the longer pair 2.5–9.5 cm long, the medium pair 0.7–4 cm long, the shorter pair reduced or to 2 cm long, the second-rank axes 4 or 6, the longer pair (0.3–)1.5–5 cm long, the medium pair (0–)0.7–2 cm long, the shorter pair 0.4–0.5 cm long, the third-rank axes (2 or) 4 or 6, the longer pair (0–)0.3–2 cm long, the medium pair (0–)0.1–0.5 cm long, the shorter pair reduced, the fourth-rank axes 2 (or 4), the longer pair 0.2–0.3 cm long, the shorter pair reduced; bracts triangular to linear, 3–5 mm long, red-brown pubescent, fringed. *Flowers* sessile; calyx cup-shaped, the tube 1 mm long, the lobes 5, triangular to barely evident, to 0.3 × 0.8 mm, puberulent, fringed; corolla white, the tube campanulate, 2.5–3 × ca. 1.5 mm, white pubescent in throat, the lobes 5, linear, 2 × 1–1.2 mm; stamens 5, the filaments 2.5–3 mm long in pins, 4–5 mm long in thrums, the anthers 1 mm long; style 4.5–5 mm long in pins, 2.5–3.5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal to slightly obovoid, 8–12(–13) mm long, 6–8(–9) mm diam., maturing red, drying black; calyx sometimes persistent as beak drying pale brown; seed dorsal surface with 6–10 irregular longitudinal furrows, the ventral surface with 1 often T-shaped longitudinal furrow (Fig. 10j).

Distribution (Fig. 17). Known from southern Mexico, primarily the Gulf coast, and Petén, Guatemala, occurring at elevations of 20–1,000 m, mostly under 200 m, in evergreen forest with equa-

torial-tropical to tropical-mountainous climate. *Psychotria flava* has been collected in flower almost exclusively February–May and in fruit throughout the year, primarily August–December.

Selected specimens examined. MEXICO. CHIAPAS: Mpio. PETÉN: Remate, on Tikal Rd., ca. 8.5 km NE of the village, 13 May 1960 (fl), *Contreras 936* (MO); Dolores, in pineland on Old Machaquila Rd., ca. 1.8 km S, 16 May 1961 (fl), *Contreras 2304* (LL).

Psychotria flava may be recognized by its large elliptic leaves drying chalky yellow-green to green-brown and by its large panicles of glomerules with three unequal pairs of secondary axes per rank (Fig. 7b). It differs from *P. costivenia* in having much larger leaves, glomerules instead of cymes in the inflorescence, and 6–10 irregular (vs. 4–5 regular) longitudinal furrows on the seed dorsal surface and one T-shaped (vs. two) longitudinal furrows on the ventral surface (Fig. 10j).

12. Psychotria grandis Swartz, Prodr., 43. 1788. *Uragoga grandis* (Sw.) Kuntze, Revis. Gen. Pl. 2: 960. 1891. TYPE: Jamaica: Jamaicae interioris occidentalis (fl), *Swartz s.n.* (holotype, S, n.v., photo, A). Cf. also Swartz, Fl. Ind. Occid. 417. 1797. Figures 10i, 19.

Tree or shrub, (1–)4–10 m tall; young branches red-brown puberulent, the bark smooth; stipules ovate, the apex acuminate, often with central keel, usually diverging from stem, the margins usually reflexed, the center paler, 10–20(–25) × 6–14 (–20) mm, glabrous or sometimes red-brown puberulent in center, sometimes fringed, caducous, leaving a pale ridge with red-brown fringe, often persistent at terminal 3–6 nodes. *Leaves* petiolate; petioles 0.3–2 cm long, glabrous, flat above; blades membranous, obovate to sometimes oblanceolate, the apex acuminate, the base attenuate, (10–)17–32(–39) × (3.5–)7.5–11(–16) cm, glabrous above, glabrous or densely puberulent below, drying green-brown to red-brown; secondary veins 13–19 pairs, diverging (65°–)70°–85°, eucamptodromous to brochidodromous, constantly arcuate, slightly elevated, glabrous or densely pubescent below, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate to slightly percurrent, the intersecondaries often conspicuous. *Inflorescences* terminal or pseudoaxillary, robust panicles of cymes; panicle branched to 5 degrees; main axis 18–33 cm long, the peduncle 11–18 cm long; secondary axes in 4–5 ranks, the first-rank axes (2 or) 4 or 6, the longer pair 5–10 cm long, the medium pair 3.5–6 cm long, the shorter pair 2.5 cm long, the second-rank axes 2 or 4, the longer pair 2.5–6 cm long, the shorter pair 0.7–4 cm long, the third-rank axes 2 or 4, subequal, 0.7–2 cm long, the fourth-rank axes 4, equal, 0.3–1 cm long, the fifth-rank axes 2, 0.3–0.5 cm long; cymes branched to 2–3 degrees; bracts triangular, ca. 2 mm long, often tomentose within; bracteoles lanceolate, 0.5–1.5 mm long, red-brown puberulent. *Flowers* sessile to pedicellate, the pedicels to 1.5 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular to barely evident, to 0.3 × 0.5 mm, puberulent; corolla white, the tube cylindrical to campanulate, 2.5 × 1.5 mm, white pubescent in throat, the lobes 5, ovate, 1.5–2 × 1 mm; stamens 5, the filaments 2 mm long in pins, 3.5–4 mm long in thrums, the anthers 0.8 mm long; style 4 mm long in pins, 2.5 mm long in

thrums, the branches linear. *Fruit* when dry spherical to slightly ellipsoidal, 5–6.5(–8) mm long, 4.5–6(–7) mm diam., maturing red, drying black or sometimes red-brown; persistent calyx inconspicuous or a minute beak, drying pale brown; seed dorsal surface with 10–15 irregular longitudinal furrows, the ventral surface with 2 very deep longitudinal furrows (Fig. 10i).

Distribution (Fig. 19). Commonly collected from Belize, Guatemala, and adjacent Honduras near the Caribbean coast and also from Nicaragua–Panama, where it reaches the Pacific side. It occurs also in the Greater Antilles—Cuba, Jamaica, Hispañola, and Puerto Rico—and Colombia, Venezuela, and Ecuador. In Central America this species ranges in elevation 0–2,000 m, reaching over 500 m only occasionally, and is found in tropical moist to premontane rain forest with equatorial to tropical-equatorial climate. *Psychotria grandis* has been collected in flower almost exclusively March–July and in fruit throughout the year, especially August–January.

Selected specimens examined. GUATEMALA. ALTA VERAPAZ: region of Cocolá, NE of Carchá, 1,200 m, 2 Apr. 1939 (fl), *Standley 70305* (F); woods between Finca Cubilgüitz and Hda. Psychotria grandis may be recognized by its large size (to 10 m tall), robust keeled stipules with margins reflexed and usually persistent at terminal 3–6 nodes, large (17–32 cm long) leaves with conspicuous intersecondary veins, large robust inflorescences, and fruit drying spherical and smooth, the latter due to the seed dorsal surface having many shallow irregular furrows instead of few deep furrows (Fig. 10i). The distinction between this species and *P. costivenia* is somewhat problematic, as it is based largely on quantitative characters, such as leaf and stipule and inflorescence size. Differences in seed cross section (10–15 irregular vs. 4–5 deep regular furrows on dorsal surface) support the distinction. The two species occur sympatrically only in northern Guatemala and southern Belize.

General puberulence is common only in Belize and Honduras. Material from Belize has the longest stipules; Guatemalan material has the largest inflorescences; and Nicaraguan fruit is generally larger than elsewhere.

13. Psychotria horizontalis Swartz, Prodr., 44. 1788. *Uragoga horizontalis* (Sw.) Kuntze, Revis. Gen. Pl. 1: 300. 1891. *Myrstiphyllum horizontalis* (Sw.) Millsp., Publ. Field Mus. Nat. Hist., Bot. Psychotria horizontalis Swartz subsp. *basicordata* Dwyer, Ann. Missouri Bot. Gard. 55: 42. 1968. TYPE: Panama. Veraguas: Isla de Coiba, Camp Aguja, 8 July 1962 (early fr), *Dwyer 2384a* (holotype, MO—2165270; isotype, MO).

Psychotria horizontalis Swartz var. *psilophylla* Steyermark, Mem. New York Bot. Gard. 23: 472. 1972. TYPE: Colombia. Magdalena: nr. Masinga Vieja, Sta. Marta, 300–450 m, May 1898–1899 (fl), *H. H. Smith 393* (holotype, NY; isotypes, F, GH).

Shrub 1–3 m tall; young stems glabrous or puberulent or ferrugineous-pubescent, the bark pale, smooth; stipules sheathing, ovate-acuminate, (2.5–)4–7 × 2–3.5 mm, puberulent to ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles (1–)2–13 mm long, glabrous to puberulent to ferrugineous-pubescent, flat or grooved above; blades membranous, elliptic or rarely ovate, the apex acute to long-acuminate, the base cuneate to sometimes cordate, the margins often crenate, (6–)7.5–15 (–17) × 3–6.5(–8) cm, glabrous above, glabrous to puberulent on midvein to puberulent below, drying dull green or sometimes red-brown; secondary veins (6–)8–11(–14) pairs, diverging (45°–)60°–75°, brochidodromous, the secondary loops far from margin (Fig. 3b), increasingly arcuate toward margin, prominulous below, glabrous or sometimes puberulent below, the axils sometimes with minute domatia below; tertiary veins evident to conspicuous, orthogonal reticulate, the loops between secondary loops and margins evident. *Inflorescences* terminal or pseudoaxillary, globose panicles of cymes; panicle branched to 3 degrees; main axis (2.5–)4–10 cm long, the peduncle rarely lacking or (2–)3–7 cm long; secondary axes in (2–)3–4 ranks, the first-rank axes 4 or 6, the longer pair (0.7–)1–2 cm long, the medium pair 0.4–1.4 cm long, the shorter pair 0.3–0.6 cm long, the second-rank axes 2 or 4, the longer pair (0.2–)0.4–0.9 cm long, the shorter pair 0.3–0.6 cm long, the third-rank axes 2, 0.1–0.3 cm long, the fourth-rank axes 2, 0.1–0.2 cm long; cymes branched to 1(–2) degrees; bracts inconspicuous, linear to tri-

angular, to 5 mm long, puberulent to ferrugineous-pubescent; bracteoles linear, to 1 mm long, puberulent to ferrugineous-pubescent. *Flowers* pedicellate, the pedicels 0.5–1.5 mm long; calyx campanulate, the tube 0.5 mm long, the lobes 5, lanceolate, (0.5–)1–2 × 0.6 mm, puberulent; corolla white, the tube cylindrical, 2.5–3.5 × 1.3–1.5 mm, white pubescent in throat, the lobes 5, lanceolate, 1.5–2 × 0.6 mm; stamens 5, the filaments (2.5–)3–3.5 mm long in pins, 5–6 mm long in thrums, the anthers 0.8–1 mm long; style (4.5–)5–6 mm long in pins, 3–3.5 mm long in thrums, the branches linear, often recurved. *Fruit* when dry ellipsoidal, 3.5–4.5(–5) mm long, 2.5–3.5(–4) mm diam., maturing red, drying red-brown, sometimes sparsely puberulent; persistent calyx of conspicuous lanceolate lobes, 1–3(–5) mm long (Fig. 9e); seed dorsal surface with 3–5 longitudinal furrows, the ventral surface with 2 longitudinal furrows (Fig. 10b).

Distribution (Fig. 16). Known from Mexico, primarily the Pacific coast from Sinaloa eastward, through Panama, ubiquitous throughout its range at elevations of 0–1,300 m, mostly below 600 m, in tropical moist to premontane wet to sometimes tropical dry forest (deciduous forest in western Mexico) with equatorial or usually tropical or sometimes subtropical-tropical climate. *Psychotria horizontalis* occurs also in Cuba, Hispaniola, Colombia, Venezuela, the Guianas, Ecuador, and Brazil. It has been collected in flower June–August in Mexico and primarily March–July throughout the rest of its range; fruiting collections come from throughout the year, primarily August–March.

All the species in synonymy have been properly synonymized before (cf. Dwyer, 1980). Infraspecific categories are not recognized herein because they have been defined in terms of variation seen within almost any population, such as the basicordate leaf blades on which *P. horizontalis* subsp. *basicordata* was based.

Psychotria horizontalis may be recognized by its leaves drying usually dull pale green, with secondary veins brochidodromous and making connecting arches far from the margin (Fig. 3b), and by its fruit with conspicuous persistent calyx of long, linear lobes (Fig. 9e).

Material from Guatemala, Belize, and Nicaragua is generally more pubescent than elsewhere in Central America. The calyx lobes, prominently persistent in fruit, are often much shorter in central Panama than elsewhere.

14. Psychotria papantlensis (Oersted) Hemsley, Biol. Cent. Amer. Bot. 50. 1881. Based on *Mapouria papantlensis* Oersted, Amér. Centr. p. 17, t. 14, fig. 5. 1863. *Uragoga papantlensis* (Oerst.) Kuntze, Revis. Gen. Pl. 2: 962. 1891. TYPE: Mexico. Veracruz: Papantla, *Liebmann s.n.* (holotype, C, n.v.). Figures 9b, 16.

Shrub or tree, 1–4 m tall; young stems glabrous, the bark pale, smooth; stipules sheathing, ovate, the apex usually biaristate, 4–9 × 2.5–6 mm, often paler in the central triangle, the margin often ciliate, often persistent at terminal 2–4 nodes, leaving a pale ridge with short red-brown fringe. *Leaves* petiolate; petioles (0.5–)1–3(–4) cm long, often diverging at right angles to stem, glabrous, flat above; blades very thin membranous, elliptic to oblanceolate, the apex acuminate, the base attenuate, (6.5–)9–14(–17) × (1.5–)2.5–5(–6) cm, glabrous above and below, drying usually pale green to sometimes pale red-brown; secondary veins 9–11 pairs, diverging 65°–75°, eucamptodromous to brochidodromous, constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3 degrees; main axis 3.5–14.5 cm long, the peduncle 2.5–11 cm long; secondary axes in 3(–4) ranks, the first-rank axes 4, the longer pair 0.6–1.7 cm long, the shorter pair 0.4–1 cm long, the second-rank axes 4, subequal, 0.3–0.8 cm long, the third-rank axes 2 or 4, subequal, 0.2–0.4 cm long, the fourth-rank axes 2, 0.1 cm long; cymes branched to 1–2(–3) degrees; bracts and bracteoles lanceolate, ca. 1 mm long, fringed, caducous. *Flowers* sessile to pedicellate, the pedicels to 0.7 mm long; calyx drying pale brown against darker petiole and receptacle, cup-shaped, the tube to 0.5 mm long, the lobes 5, triangular, 0.5 × 0.5 mm, glabrous to minutely ciliate; corolla white, the tube cylindrical, 4–5 × 1 mm, sparsely white pubescent in throat, the lobes 5, lanceolate, 1.5–2.5 × 0.8–1 mm; stamens 5, the filaments 3 mm long in pins, 6–7.5 mm long in thrums, the anthers 1.3–2 mm long; style 6 mm long in pins, 4–5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoidal, (6–)7–7.5 mm long, (4–)4.5–5 mm diam., maturing red, drying black; persistent calyx a tubular beak, drying pale green, 0.5–1 mm long (Fig. 9b); seed dorsal surface with 4 shallow longitudinal furrows, the ventral surface with 2 deep incompletely divided longitudinal furrows.

Distribution (Fig. 16). Common in southern Mexico through Petén, Guatemala, into southwestern Belize, at 0–400 m elevation in evergreen forest with usually equatorial-tropical climate. *Psychotria papantlensis* has been collected in flower March–June and in fruit in March and July–December.

Psychotria papantlensis may be recognized by its elliptic long-petiolate leaves drying pale green and by its calyx drying conspicuously pale in flower and in fruit, when it contrasts markedly with the black-drying ellipsoidal fruit (Fig. 9b).

As in several species, the corolla tube of the thrum flower morph is longer than that of the pin morph (5 mm vs. 4 mm); but the species appears otherwise normally distylous.

15. Psychotria pleuropoda Donnell-Smith, Bot. Gaz. (Crawfordsville) 40: 5. 1905. TYPE: Guatemala. Alta Verapaz: Cubilgüitz, 350 m, Aug. 1903 (fr), *H. von Tuerckheim 8529* (lectotype designated herein, GH; isolectotypes, US—2 sheets, fragments, F, US). Figure 17.

Shrub 0.5–5 m tall; young stems glabrous, the bark pale, furrowed longitudinally; stipules ovate, the apex biacuminate, the central triangle drying pale green, 10–17 × 4–6 mm, fringed, persistent at terminal 3–5 nodes, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles (0.2–)0.5–1 cm long, glabrous, terete; blades membranous, narrow-oblanceolate, the apex long-acuminate, the base attenuate, (7–)12–21 × (1–)1.3–2.7 cm, glabrous above and below, drying dull pale green-brown to sometimes red-brown; secondary veins 15–18 pairs, diverging 60°–75°, eucamptodromous to brochidodromous, constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins evident, percurrent, the intersecondaries especially evident. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3 degrees; main axis (1.5–)2.5–12 cm long, the peduncle (1–)2–9.5 cm long; secondary axes in 1–2 ranks, the first-rank axes 4, the longer pair 0.3–1.3 cm long, the shorter pair 0.2–1 cm long, the second-rank axes 2 or 4, subequal, 0.2–0.5 cm long; cymes branched to 1–2 degrees; bracts linear, to 5 mm long, ciliate; bracteoles irregular, ca. 1 mm long, ciliate. *Flowers* sessile to pedicellate, the pedicels to 1 mm long; calyx drying pale brown against darker petiole and receptacle, cylindrical, the tube 1 mm long, the lobes 5, triangular, barely evident, minutely ciliate; corolla white, the tube cylindrical, 2.5–3 × 1.5 mm, white pubescent in throat, the lobes 5, lanceolate, 2.5 × 1 mm; stamens 5, the filaments 3 mm long in pins, 3.5–4 mm long in thrums, the anthers 0.8–1 mm long; style 5 mm long in pins, 2.5–3 mm long in thrums, the branches clublike in pins and linear in thrums. *Fruit* when dry ellipsoidal, (5.5–)6 mm long, (4.5–)5 mm diam., maturing red, drying black or green-brown; persistent calyx a tubular beak ca. 1 mm long; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 deep sometimes incompletely divided longitudinal furrows.

Distribution (Fig. 17). Known from Tabasco, Mexico, northern Guatemala, and southern Belize, at 50–500 m elevation in evergreen forest with equatorial-tropical to equatorial-mountainous climate. This species has been collected in flower February–June and in fruit August–February.

Selected specimens examined. MEXICO. TABASCO: Mpio. Tacotalpa, 3 km a pie a E del ejido Lázaro Cárdenas, 50 m, 10 May 1979 (fl), *Cowan 2069* (NY). GUATEMALA. ALTA VERAPAZ: Montaña Yxocubvain, 4 km W of Cubilgüitz, 300–500 m, 12 Mar. 1942 (fl), *Steyermark 44990* (F—2 sheets, GH, NY). Otoxha, 200 m, Feb. 1973 (st), *Boster s.n.* (ECON); trail from Columbia Forest Station to Esperanza, 3–6 km W of San José rd., 180–330 m, 13 June 1973 (fl), *Gentry 8172a*

(F, NY); Deep River Forest Reserve, limestone-derived soil, Feb. 1945 (fl), *Lamb 54, 62* (F).

Psychotria pleuropoda may be recognized readily by its narrow-oblanceolate (length/width = 8–10) leaves unique in subg. *Psychotria* in Mesoamerica. It differs from *P. costivenia* by having very narrow leaf blades and inflorescences with relatively short secondary axes in only 1–2 (vs. ca. 4) ranks. The persistent calyx tube in fruit is also distinctive.

16. Psychotria sylvivaga Standley, J. Wash. Acad. Sci. 18: 274. 1928. TYPE: Costa Rica. Heredia: Yerba Buena, NE of San Isidro, 2,000 m, 28 Feb. 1926 (fr), *Standley & Valerio 49989* (holotype, US). Figure 17.

Shrub 2–3 m tall; young stems sparsely red-brown puberulent, the bark pale, furrowed longitudinally; stipules broadly ovate, 9–12 × 5–6 mm, glabrous, sometimes ciliate near base, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1–2 cm long, glabrous, flat above; blades membranous to sometimes subcoriaceous, elliptic to oblanceolate, the apex acuminate to caudate, the base attenuate, (8.5–)10–17 × (2.5–)3–4.5(–5) cm, glabrous above and below, drying green-brown to red-brown; secondary veins 11–14 pairs, diverging (60°–)65°–75°(–80°), brochidodromous, constantly arcuate, elevated below, glabrous, the axils sometimes with minute tufts of red-brown hairs; tertiary veins evident to inconspicuous, orthogonal reticulate, the intersecondaries often evident. *Inflorescences* terminal or pseudoaxillary, sparse panicles of cymes; panicle branched to 4 degrees; main axis 9.5–14 cm long, the peduncle 6–7.5 cm long; secondary axes in (3–)4 ranks, the first-rank axes 2, 2–3.2 cm long, the second-rank axes 2, 0.8–1.2 cm long, the third-rank axes 2, 0.4–0.8 cm long, the fourth-rank axes 2, 0.2–0.5 cm long; cymes branched to 1 degree; bracts lanceolate, 3 mm long, glabrous; bracteoles triangular, to 1 mm long, red-brown ciliate. *Flowers* pedicellate, the pedicels to 1 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular, 0.5 mm long, puberulent; mature corolla, stamens, and style not seen. *Fruit* when dry spherical, 4.5–5 mm long, 4–5 mm diam., maturing red, drying red-black; persistent calyx 1 mm long, drying pale brown; seed dorsal surface with 6–8 often irregular longitudinal furrows, the ventral surface with 2 medium-deep often plus ca. 4 irregular longitudinal furrows.

Distribution (Fig. 17). Known from southern Alajuela and San José, Costa Rica, at 2,000–2,200 m elevation in a region of premontane to low montane rain forest with equatorial-mountainous climate. *Psychotria sylvivaga* has been collected in flower in December and in fruit in December and February.

Additional specimens examined. COSTA RICA. SAN JOSÉ: nr. Laguna de la Escuadra, NE of El Copey, 2,000–2,200 m, 16 Dec. 1925 (fr), *Standley 41924* (A, US), *41974* (F, US); Laguna de la Chonta, NE of Sta. María de Dota, 2,000–2,100 m, 18 Dec. 1925 (fl, early fr), *Standley 42212* (K, US).

Psychotria sylvivaga may be recognized by its elliptic to oblanceolate leaves drying green-brown to red-brown with brochidodromous secondary veins and evident intersecondaries and by its fruit with persistent calyx a conspicuous tube.

Standley described a mature flower with corolla tube 5 × 1.2 mm, the lobes triangular-ovate, 1.5 mm long, in his original description, but I was unable to find a mature flower.

DIANTHOVEUS: A NEW GENUS OF CYCLANTHACEAE[1]

Barry E. Hammel[2] *and George J. Wilder*[3]

Abstract

Dianthoveus cremnophilus, a terrestrial Cyclanthaceae from southwestern Colombia to northern Ecuador, is described as a new genus and species. The cupules at the base of the stamens and the long, narrow, moderately flattened seeds are unique. Cladistic analysis supports the hypothesis that leaf idioblasts with randomly oriented styloids (leaves scabrous when dry), root styloids, sessile anthers, and inaperturate pollen are synapomorphies with the widespread, monospecific *Evodianthus*. The new genus differs fundamentally from *Evodianthus* by having a uniseriate staminate perianth and in seed shape and seed coat structure. *Dianthoveus* shares additional uncommon characters with *Evodianthus* (e.g., separate fruits, terminal inflorescences, symmetrical flowers) that are not unique in the family. With *Schultesiophytum* it shares some of these uncommon characters but uniquely shares only laminar anther appendages. Although *Dianthoveus* and *Dicranopygium* subgenus *Gleasonianthus* uniquely share staminate flowers with eglandular tepals, no other characters suggest a close relationship between them.

Exploration of tropical wet forests in southern Central America and northwestern South America in recent years has greatly increased the number of collections and species known from these areas. This was especially predictable for the Cyclanthaceae, which are restricted to the wettest, often least-explored habitats (Grayum & Hammel, 1982). Since the time of Harling's (1958) monograph, which included 178 species in 11 genera, 29 new species have been added to this predominantly epiphytic family. More than 30 additional new species are now known from Central America and the Chocó region of South America alone (Hammel, unpubl.). However, only one new subgenus (Wilder, 1978) and no other supraspecific taxa have been described. In fact, in recent years only 10 genera have been recognized; *Pseudoludovia* is thought to be a mixed collection: a spadix, perhaps of a *Sphaeradenia*, and leaves of *Ludovia* (Wilder, 1978). Harling suggested that on further study it might be possible and logical to subdivide the three largest genera into additional genera, and for *Sphaeradenia* this reclassification is imminent (R. Eriksson, in press). *Dianthoveus*, the name an anagram of "Evodianthus," is a totally novel, monotypic genus.

This plant was first described and illustrated, as a short-stemmed terrestrial, in *The Flora of the Río Palenque Science Center* (Dodson & Gentry, 1978), where it was identified as *Asplundia vagans* Harl., a common root-climbing epiphyte of Central and South America. Examination of specimens of Cyclanthaceae in the herbarium at the Marie Selby Botanical Gardens, where vouchers for the Río Palenque florula are deposited, revealed that the plant was neither poorly illustrated nor a terrestrial form of *A. vagans*, but rather something problematic, exhibiting unusual characters of several genera. This stimulated two field trips to Ecuador, which, along with laboratory studies, convinced us that the plant is an undescribed genus.

Materials and Methods

In total, well over 200 individuals in seven populations were examined in the field. Plants at various stages—from early anthesis through ripe infructescences to peduncle remains—were fixed in FAA for anatomical and morphological studies. Twenty-eight fluid-preserved collections at these stages were made, and numerous herbarium vouchers and live plants were collected. In the field, live specimens were examined to determine inflorescence position, presence/absence of latex, drying qualities of wounded and air-dried leaves, and features of leaf color and texture.

[1] Supported by grants from the National Science Foundation (BSR-8508463) and the Jessie Noyes Smith Foundation to B. Hammel and a Grant-in-Aid to G. Wilder from the Cleveland State University. We thank Jack Fogerty, Mary Merello and Cheryl Roesel for technical assistance, John Myers for drawings, and Henk van der Werff for the Latin diagnosis. We thank Jorge Crisci, Michael Grayum, and W. John Kress for helpful discussion and criticism of an earlier draft of this paper and Gerrit Davidse and Lucinda McDade for critical review of the submitted manuscript.

Plants preserved in the field in FAA were drained of fluid and transported in sealed plastic bags within a large plastic container. Subsequently they were washed in water for several days and then stored in an aqueous solution of 5% glycerin and 50% ethanol. All measurements were taken from live or fluid-preserved plants at populations along the Río Pilatón (*Hammel & Wilder 16058, 16059, 16066, 16067* & *16074*). Leaf measurements were taken from a total of 17 adult leaves from three individuals. Inflorescence measurements were taken from four individuals, and flower measurements come from ten flowers in each inflorescence. Infructescence measurements were from ten individuals, and fruit measurements from ten fruits in each of four individuals. For anatomical studies, material of laminae, roots, and stems was prepared according to the methods of Wilder (1985). Seeds were taken from mature preserved infructescences embedded in Tissue Tek OTC polysaccharide compound, frozen, and sectioned in a cryostat. Sections were mounted, stained with toluidine blue, and viewed with a bright field microscope. Pollen was prepared with and without acetolysis and with and without critical point drying, coated with gold, and viewed with a Hitachi S45D scanning electron microscope. Detailed studies on the morphology and development of vegetative parts and inflorescences, and the anatomy of laminae, first-order roots, and rhizomes are in progress (Wilder, unpubl.).

In order to test our initial hypothesis of relationship of the new genus to *Evodianthus* we selected 22 characters for the 11 genera of Cyclanthaceae (Table 1), developed a character-by-taxon matrix (Table 2), and analyzed the data using PAUP for microcomputer, a maximum parsimony technique (Swofford, 1985). All characters were unweighted, but the four character states of "habit" were restricted to a specific order (Table 1 and discussion below). Since no logical basis was apparent for restricting the order of character transformations of other multistate characters, all other characters were treated as unordered. Characters with variable states for a particular genus were coded as missing (Pimentel & Riggins, 1987). Autapomorphies for each of the genera were not included in the analysis.

Collections made in December 1988 were added in proof and not considered in the counts and measurements.

TABLE 1. Characters and character states for the genera of Cyclanthaceae. Characters found only in one genus (autapomorphies) are not included.

A = Placentation: 0 = parietal, 1 = apical
B = Fruit fusion: 0 = some, 1 = none
C = Fruit type: 0 = other, 1 = succulent pixis
D = Seed shape: 0 = terete, 1 = moderately flattened, 2 = strongly flattened
E = Orientation of cells of testa: 0 = horizontal, 1 = vertical
F = Outer layer of testa with enlarged, dark cells: 0 = no, 1 = yes
G = Spinules on wall of inner layer of testa integument: 0 = no, 1 = yes
H = Inner tangential and radial walls of inner layer of integument equally much thickened: 0 = yes, 1 = no
I = Inflorescence position: 0 = terminal, 1 = lateral
J = Anther appendages: 0 = none, 1 = laminar-apiculate, 2 = globular
K = Phyllotaxis: 0 = distichous, 1 = spiral
L = Glands on staminate tepals: 0 = absent, 1 = present
M = Staminate flower symmetrical: 0 = yes, 1 = no
N = Staminate flower funnel-shaped: 0 = yes, 1 = no
O = Pollen: 0 = aperturate, 1 = inaperturate
P = Leaf styloids: 0 = unidirectional, 1 = omni, 2 = absent
Q = Birefringent cells in leaves: 0 = absent, 1 = present
R = Anthers: 0 = not sessile, 1 = sessile (no basal bulb or filament)
S = Habit:
0 = terrestrial
a: 1 = epiphyte
b: 1 = on rocks
c: 1 = climber
T = Root styloids: 0 = absent, 1 = present

Terrestrial herbaceous plant, often forming clumps by vegetative branching; the rhizomes 7–53 cm long, to about 6 cm diam. in mature specimens, often exposed and held erect by numerous stout, monomorphic, adventitious roots up to 75 cm long and 0.85 cm diam. Foliage leaves of adult plants 145–271.5 cm long, with spiral (dispersed, sensu Harling) phyllotaxy, crowded on the rhizome at internodes mostly less than 1 cm apart, eventually detaching and leaving the naked rhizome with well-defined leaf scars; sheaths 52–101 cm long, dull green and remaining intact; petioles 21–77 cm long; lamina unicostate or rarely and inconspicuously subtricostate, bifid to ½ or slightly less, 72–107 cm long, 16.5–30 cm wide at the base of the median sinus, the segments 9–16 cm wide; each half of the lamina with 19–26 folds, lanceolate with a short-acuminate tip, dark satiny green above, dull and paler below, scabrous when dry. Inflorescences solitary and terminal but becoming laterally displaced by the subtending, precociously expanding renewal bud. Peduncles 25–34 cm long at anthesis, becoming 41–61 cm long and curving down in mature fruiting stage, 1.4–1.8 cm diam. Spathes of two kinds, both persisting until very late flowering stage: 3 conspicuous spathes, thick, green and fleshy, differentiated into sheath, lamina, and sometimes petiole, 9.5–25.8 cm long, ca. 5–6 cm wide, ± clustered and inserted no more than 3 cm below the spadix, collectively surrounding the spadix, the lowermost much larger than the upper 2 and unusual in bearing petiolate and often bifid lamina; up to 6 inconspicuous spathes, comprising membranous greenish white scale leaves, up to 4.7 cm long and 1 cm wide, inserted above the conspicuous spathes and all ± at one level, usually subtending flowers and often inserted above the base of the spadix, arising only from one side of the inflorescence. Spadices cylindrical, at anthesis 7.8–9.5 cm long, 2.6–3.1 cm diam., sordid white, in ripe fruiting stage becoming 11–14.8 cm long, 4–6 cm diam., green. Staminate flowers ± obpyramidal, 3.3–5.5 mm long; receptacle approximately triangular in top view, ca. 2–3.3 mm wide, adorned with numerous multicellular papillae forming a cupule around the base of each anther; perianth lobes 10–18, thin and narrowly triangular-acuminate, (1–)1.3–2.7 mm long, eglandular, distributed ± evenly on the receptacle margin; stamens 19–32, the anthers ± elliptic but often widest above the middle, 0.7–1.1 mm long, 0.4–0.8 mm wide, the thecae occupying the lower ½–⅔ of the anther and separated by the broad upper portion of connective, this terminating in a laminar apiculate tip; filaments minute, 0.1–0.2 mm long or lacking; basal bulbs lacking. Pollen grains mostly ovoid but varying to nearly globose, 15–21.5 μm long, 14–15.5 μm wide, psilate, inaperturate. Pistillate flowers free to base, narrowly turbinate, at anthesis 3–3.5 mm long (from base

to top of stigma), 3.8–4.1 mm wide, at ripe fruiting stage becoming 2.1–2.4 cm long, 1.5–1.7 cm wide, green at maturity; tepals free to base (partially connate in age), arising from the top of the inferior ovary, long-acuminate, the tips folding over the stigmas and then curving out, at anthesis 2–4.3 mm long, 2–4.3 mm wide, in fruiting stages the tips often breaking off, becoming acute to rounded, 1.5–3.2 mm long, 4.5–9.5 mm wide; staminodia white, to ca. 9.5 cm long, ca. 1.5 mm diam., the distal ends apiculate, relatively flattened and attenuated but otherwise identical to an anther; styles at anthesis 0.9–2 mm tall, in fruiting stages 1–2.5 mm tall; stigmas convex in side view and slightly uncinate, extending between the tepals, at anthesis 1.2–3 mm long, 0.7–2 mm wide, in mature fruiting stages 3.5–4.2 mm long, 2–3.7 mm wide; stigmatic crest seen from above linear, papillate and sometimes sulcate; placentae 4, parietal. Seeds fusiform but moderately flattened, 1.4–2.45 mm long, 0.3–0.6 mm wide, dark amber-colored; seed coat with tannin and mucus; embryo lacking starch. Figure 1.

Distribution and habitat. Known only from wet forest in the Andean foothills of southwestern Colombia and northern Ecuador. In Colombia the species has been found only on the Pacific slope at mid elevations, but in Ecuador it is known from between 150 to 1,200 m elevation and occurs on both sides of the Andes.

Paratypes. COLOMBIA. NARIÑO: road from El Espino to Tumaco, ca. 16 km W of Ricaurte, 850 m, 18 Nov. 1986 (sterile), *B. Hammel & R. Bernal 15735* (MO); 7 Dec. 1988 (infr), *B. Hammel 17135* (COL, MO). ECUADOR. LOS RÍOS: between Santo Domingo and Quevedo, Centinela ridge, 13 km E of Patricia Pilar, 300 m, 1 Dec. 1986 (infr), *B. Hammel & J. Trainer 15846* (MO); Río Palenque Science Center, 2 km S of Patricia Pilar, common plant on creek bank, 150–220 m, 5–14 Mar. 1977 (young infr), *C. Wilder 17234* (GB, MO, PSO, QCA); Santo Domingo de los Colorados to Quito, Río Pilatón valley, 13 km E of Santo Domingo, Tinalandia resort, on steep slope along stream in forest, 800 m, 30 Nov. 1986 (old infl and young infr), *B. Hammel & J. Trainer 15820* (CAS, K, MO, US); 20 June 1987 (infl), *B. Hammel & G. Wilder 16066* (MO); (infl and infr), *B. Hammel & G. Wilder 16067* (COL, F, MO, QCA); 18 km E of Santo Domingo, on vertical slope just behind CEPE gas station, 750 m, 22 June 1987 (infl), *B. Hammel & G. Wilder 16080* (MO, US); 32 km E of Santo Domingo, N of highway and Río Pilatón, 850 m, 19 June 1987 (infl), *B. Hammel & G. Wilder 16059* (MO); 34.5 km E of Santo Domingo, on steep slopes S of highway, 1,100 m, 21 June 1987 (infl and infr), *B. Hammel & G. Wilder 16074* (COL, GB, GH, MO, QCA); same locality as type, 6 Dec. 1986 (infr), *B. Hammel & J. Trainer 15890* (MO, SEL).

Dianthoveus cremnophilus is robust, short-stemmed, and terrestrial (Fig. 3) but, as indicated by its epithet, it is a "cliff-loving" plant (Fig. 4). At many of the sites along the Río Pilatón we were able to collect plants only by pulling ourselves up nearly vertical slopes, using roots and stems as hand holds. Several large populations, including the type, were growing on dripping and mossy rock walls. All of the sites were along small streams or gullies or on wet, shaded slopes in isolated patches of relatively undisturbed forest. Even at Río Palenque, where the terrain is essentially a rolling plain, plants occur only on steep banks along small streams in the forest. Plants at two of the sites had been exposed by recent felling of forest cover and showed signs of sun damage.

Although *Dianthoveus* is locally abundant and probably formerly occurred throughout the wet lowlands and foothills of the Andes in northern

FIGURES 3, 4. Habit and habitat of *Dianthoveus cremnophilus*, at type locality.—3. Habit; divisions on tape are 10 cm each.—4. Habitat; plants were often abundant on wet, vertical slopes.

Ecuador, it seems not to occur outside of that area. Attempts to find it have failed on the Amazonian side of the Andes in southern Colombia near Mocoa in Putumayo Province, and in the Pacific lowlands of southern Colombia (near Barbacoas) in habitat similar to that of the adjacent Ecuadorian localities.

Phenology. Nearly all of the collections of *Dianthoveus* have been made from June through December, which spans the primary dry season for humid areas of northwestern Ecuador (Dodson & Gentry, 1978). Our search of numerous large populations at five different localities during June revealed four phenological classes: (1) most plants bore no outward sign of fertile structures (N = ca. 200) except for some with old peduncle stubs; (2) next most abundant were plants with remnants of old infructescences, primarily long-rotten peduncles (N = ca. 30); (3) we saw and collected only 12 individuals with young to mature infructescences, and (4) five individuals with immature to old inflorescences. At the type locality, only fruiting plants were observed in December of 1986 and in June of 1987. The single mid wet season collection has a young infructescence. Individuals apparently bear a single inflorescence per rhizome at one time. Our studies suggest that *Dianthoveus* flowers and fruits sporadically throughout the year. From the relatively frequent plants with peduncle remnants during June, we infer a somewhat higher flowering frequency during January through March, i.e., in the middle of the rainy season, a common pattern in other Cyclanthaceae.

Development and morphology of fertile structures. The peduncles are most flexible at the base and are held erect at anthesis by the tightly overlapping leaf sheaths. Later, as the infructescence becomes heavier, the elongating peduncle bends so that the mature infructescence is held either horizontally or nearly pendent. The peduncle is persistent long after the fruits have been shed, and plants are often found with the fibrous remains of peduncle firmly attached to the rhizome. Both conspicuous and inconspicuous spathes persist into very late flowering stage with the largest, lowermost spathe persisting longest. Spathe scars are indistinct.

The fruits of *Dianthoveus* remain green or become light brown at maturity and apparently offer little attraction to dispersers; they are neither fragrant nor very juicy. We found seeds germinating in the debris of an old infructescence at the base of a plant, and often seedlings were found on wet rock walls below the mother plants. Such gravity or "flush dispersal" is probably usual for the genus; however, we found several fruits on one infructescence with the distinctive prints of bat teeth. In *Evodianthus* the berries become bright pale orange and very juicy at maturity and are undoubtedly dispersed by birds or bats.

Staminate flowers are tightly crowded among the pistillate flowers throughout development and persist into the early stages of fruiting; remains of the pedicels can be found even among mature fruits. Tepals often vary in length within one flower and usually with a tendency for the longest tepals to be together, making the flower slightly asymmetrical. This asymmetry, however, appears to be random with respect to the associated pistillate flower; the longest tepals, for example, may or may not face the pistillate flower. The tepals are thin and become brown at anthesis. They are always without resin glandules.

Tepals of the pistillate flowers are quite similar in shape and texture to those of the staminate flowers, an unusual condition for the family. Their apices are thin, nearly filamentous, and at first lie closely appressed to the stigmas and to the staminodia. In fruiting stages the tepals become much broader—only acute to rounded—and the tips often break off, leaving an irregular ridge around the stigmas, which no longer protrude and are often turned upward rather than uncinate. The sides of the fruit converge basally towards the long axis of the spadix into a narrow, vertical, lenticular shape.

Relationships. A simple comparison of the new genus with others in the family suggests that it is closely related to *Evodianthus*. Most notably, both genera and no others have leaves that are scabrous when dry. Anatomically, this translates into "styloid sacs [which] are normally elongated in all directions within the mesophyll, routinely crossing cell layers" (Wilder, 1985). All other Cyclanthaceae with styloid sacs have them elongated only parallel to the longitudinal files of parenchyma cells and confined to one layer. Only *Evodianthus* and *Dianthoveus* have styloid sacs in roots. Pollen of both genera is the smallest in the family and inaperturate (Figs. 5, 6), in contrast to the aperturate pollen of all other genera. Both genera have very short or no filaments and lack basal bulbs. Both have unicostate or cryptically subtricostate leaves, separate fruits, symmetrical staminate flowers, and terminal inflorescences, characters unusual in the family but shared with other genera (Table 3).

Features of staminate flowers and seeds have been especially important for delimiting suprageneric taxa within the Cyclanthaceae (Gleason,

TABLE 3. Hierarchy of unusual characters of *Dianthoveus* and the genera sharing them.

Character	Shared with
Papillate receptacles	none
Long-acuminate tepals	none
Inconspicuous spathes	*Cyclanthus*
Eglandular staminate tepals	*Dicranopygium* subg. *Gleasonianthus*
Apiculate anther appendages	*Schultesiophytum*
Scabrous leaves	*Evodianthus*
Styloids in roots	*Evodianthus*
Inaperturate pollen grains	*Evodianthus*
Sessile anthers	*Evodianthus*
Spinules on wall of seed coat	*Carludovica*, *Thoracocarpus*
Moderately flattened seeds	*Carludovica*, *Schultesiophytum*
Separate fruits	*Evodianthus*, *Schultesiophytum*, *Sphaeradenia*
Terminal inflorescences	*Evodianthus*, *Carludovica*, *Cyclanthus*
Clustered spathes	*Evodianthus*, *Carludovica*, *Schultesiophytum*, *Dicranopygium*

1929; Harling, 1958; Wilder, 1978). In the new genus, characters of both these structures differ markedly from those of *Evodianthus*, from which the former differs by its lack of a biseriate perianth (unique to *Evodianthus*), its lack of a funnelform receptacle in the staminate flowers (found in *Evodianthus* and several other genera), and by its only moderately flattened and narrowly elliptic seeds (Fig. 7). *Evodianthus*, as well as *Asplundia* and *Thoracocarpus*, have broadly elliptic, strongly flattened seeds. The seed coat structure also differs markedly from that of *Evodianthus* (see below). The new genus is further distinguished by the eglandular, acuminate tepals of the staminate flowers (which are similar only to those of *Dicranopygium* subgenus *Gleasonianthus*), the apiculate laminar appendages of the anthers (shared only with *Schultesiophytum*), and especially the peculiar papillate receptacle of the staminate flowers (Fig. 8).

Seed coat structure is variable among genera of Cyclanthaceae and was an important consideration in Harling's delimitation of genera in the family. We have interpreted the wall layers by focusing on the inner and outer cuticles, described by Harling and present in all genera. The seed coat of *Dianthoveus* (Fig. 9) is similar to those of *Carludovica* and *Thoracocarpus*; the innermost layer of the outer integument in all three genera has relatively large thin-walled cells with spinulose wall ingrowths on the inner tangential walls, whereas *Evodianthus* lacks these spinules (Harling, 1958: 38–43).

Evodianthus occurs rarely as a terrestrial plant and rarely with leaf blades nearly as large as those of the new genus. With fresh material, the less glossy (more satiny) aspect of the upper leaf surface, the larger size, and constantly terrestrial and short-stemmed habit of *Dianthoveus* distinguish it vegetatively from *Evodianthus*. Due to the similarity of these two genera, *Evodianthus* specimens (and all other Cyclanthaceae) at COL, F, MO, QCA, and SEL were examined to see if the new genus was included among them; it was not.

PHYLOGENETIC ANALYSIS

The Cyclanthaceae are widely considered to be monophyletic (Dahlgren et al., 1985; French et al., 1983), and for the most part each of the 11 genera also has at least one clear apomorphy supporting its monophyly. Within Cyclanthaceae, *Cyclanthus* possesses many unique and highly derived features (Dahlgren et al., 1985; Harling, 1958; Wilder & Harris, 1982) and apparently shares only ancestral characters with other genera. The similarity of seeds of *Cyclanthus* to those of Pan-

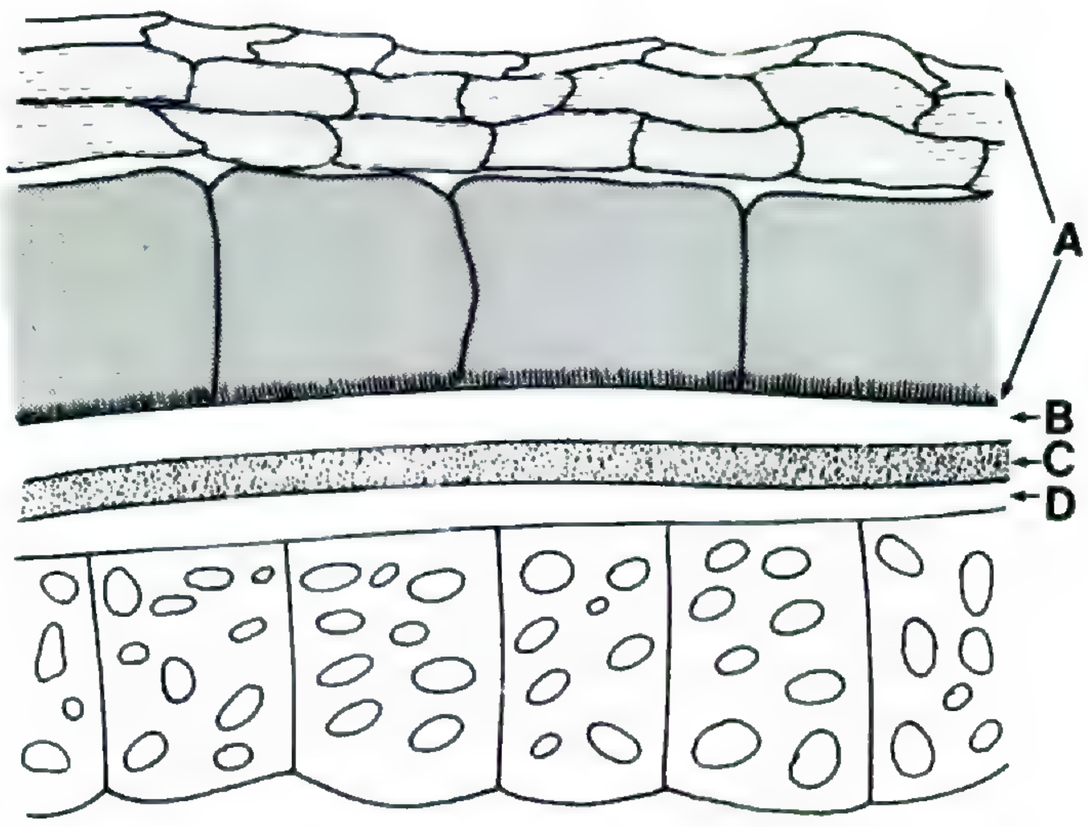

FIGURE 9. Seed coat of *Dianthoveus cremnophilus*.—A. Outer integument; lower arrow points to spinulose wall ingrowths.—B. Outer cuticle.—C. Inner integument.—D. Inner cuticle; *Hammel & Wilder 16058*.

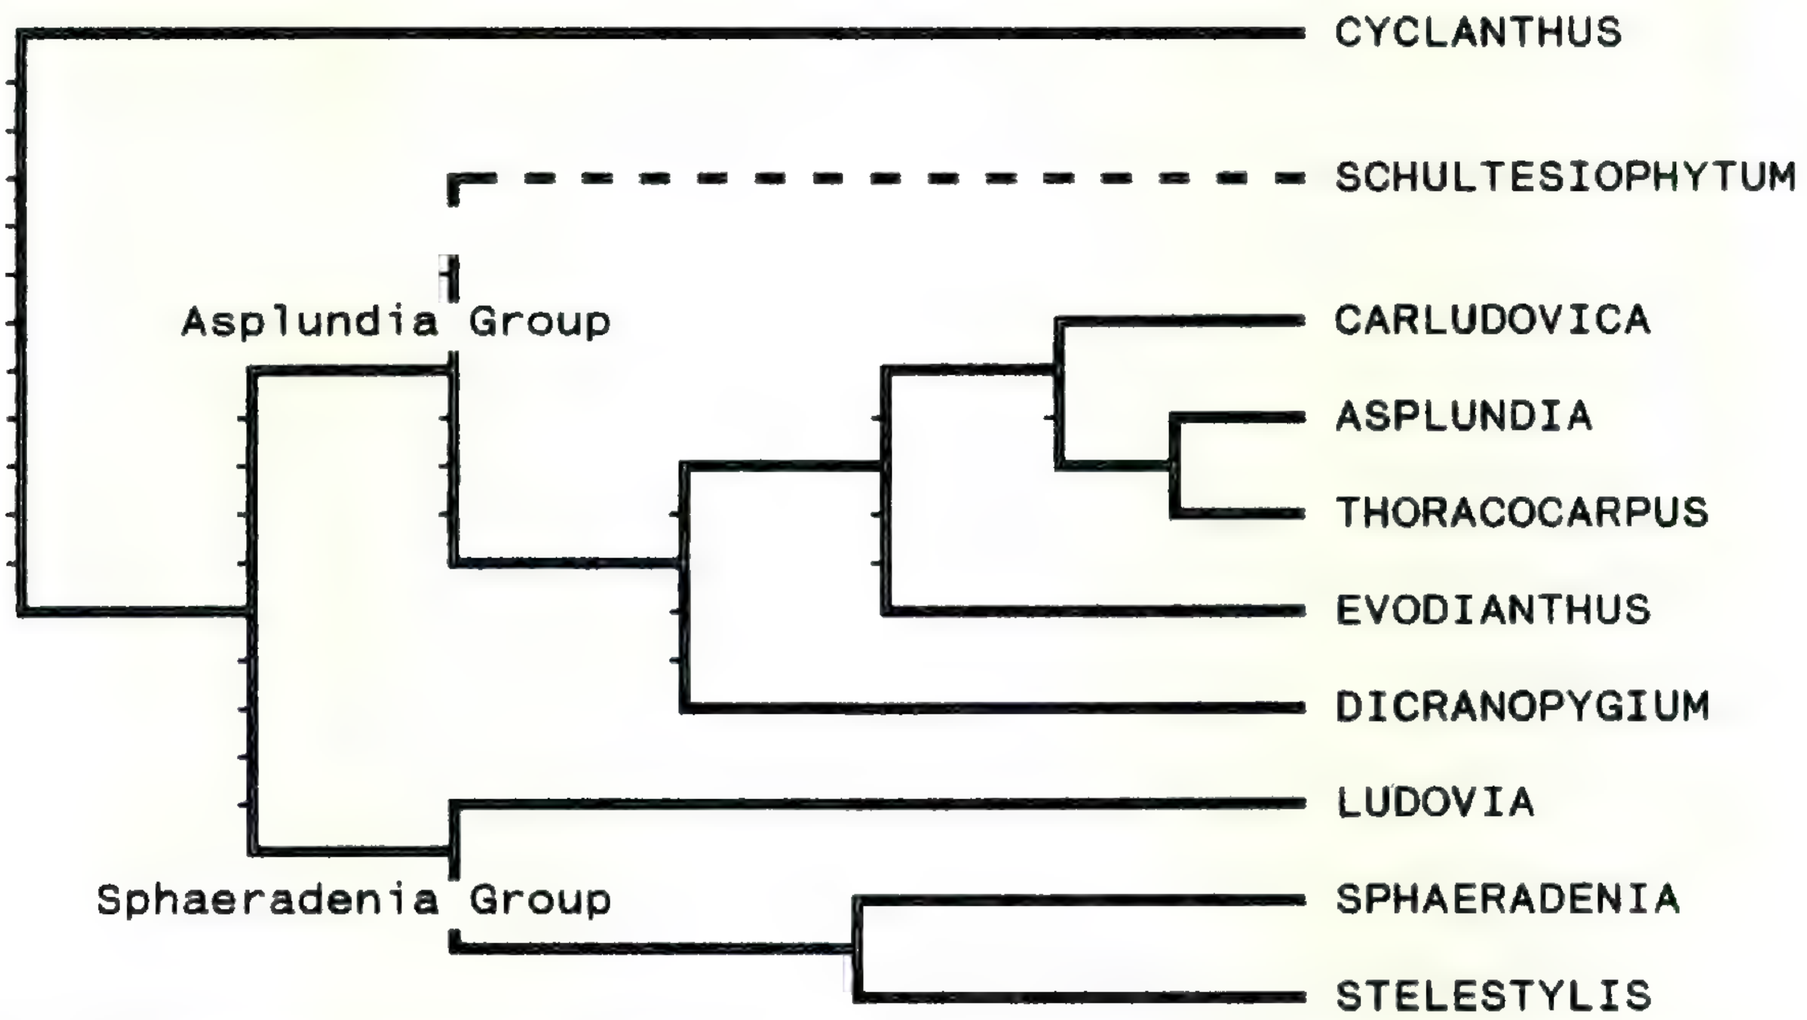

FIGURE 10. Phylogenetic scheme of Cyclanthaceae. Dashed line is Harling's convention for indicating highly uncertain position of *Schultesiophytum*—staminate flowers were unknown. Adapted from Harling (1958).

danaceae, especially in the genus *Freycinetia*, figured strongly in Harling's "geneological tree" (1958) for the genera of Cyclanthaceae (Fig. 10), including division of the family into two subfamilies. Furthermore, a preliminary analysis using *Freycinetia* (Pandanaceae) as the outgroup resulted in three trees, all of which supported the Cyclanthoideae/Carludovicoideae subdivision of the family (Hammel, unpubl.).

Thus, as a starting point we accepted a sister group relationship for the two subfamilies of Cyclanthaceae and postulated hypothetical ancestor for the Carludovicoideae based on the presumably ancestral characters of *Cyclanthus*, the only genus in the Cyclanthoideae. *Cyclanthus* contains only two species and is monomorphic for the characters analyzed; variability within the hypothetical ancestor was therefore not a problem. Characters not obviously comparable between the two subfamilies, e.g., floral symmetry (*Cyclanthus* lacks distinct, meristic floral units at maturity) were coded either by looking outside the family to the Araceae, Arecaceae, and Pandanaceae, where Harling and others have indicated the most likely affinity with the Cyclanthaceae, or by designating them as missing characters for *Cyclanthus*.

Harling's (1958) proposed relationships among genera in his "*Asplundia* group," which would include the new genus, by his own admission were quite tentative (Fig. 10). The main purpose of our analysis was to make an explicit statement as to the placement of *Dianthoveus* within the family, using characters from Harling and new characters. Discussion of those aspects of the character analysis not directly pertinent to the new genus and comparison of the phylogeny produced with these methods to that of Harling will be presented elsewhere (Hammel, unpubl.).

Character coding. Several characters were coded as missing in *Cyclanthus*, the hypothetical ancestor for this analysis. For example, although the pistillate "units" seem to demonstrate a remarkable extreme of fusion among parts, they readily dehisce from each other at maturity. Furthermore, it is difficult to judge an immediate ancestral state for this character from outgroup comparison; fruits are commonly fused in Pandanaceae, rarely in Araceae, and sometimes in Arecaceae. Note also that whereas Dahlgren & Rasmussen (1983) cited "indehiscent fruits" as a possible synapomorphy for their Areciflorae complex (Arecaceae, Cyclanthaceae, Pandanaceae), the berries in most species of Cyclanthaceae are dehiscent by apical caps (*Thoracocarpus*, all but one species of *Asplundia*, and most species of the *Sphaeradenia* group; Hammel, unpubl.). Live, mature infructescences of Pandanaceae, especially *Freycinetia*, need to be examined for comparison.

Characters of the staminate flowers were likewise difficult to polarize with reference to *Cyclanthus*, which at maturity has only amerous rows of stamens. Pandanaceae also have amerous and apetalous staminate inflorescences. Flowers were coded as primitively symmetrical by reference to Araceae and Arecaceae. Presence/absence of glands on tepals and shape of perianth were coded as missing data.

The phyllotaxy in *Cyclanthus* is spirodistichous (Wilder, 1981), making the coding of this char-

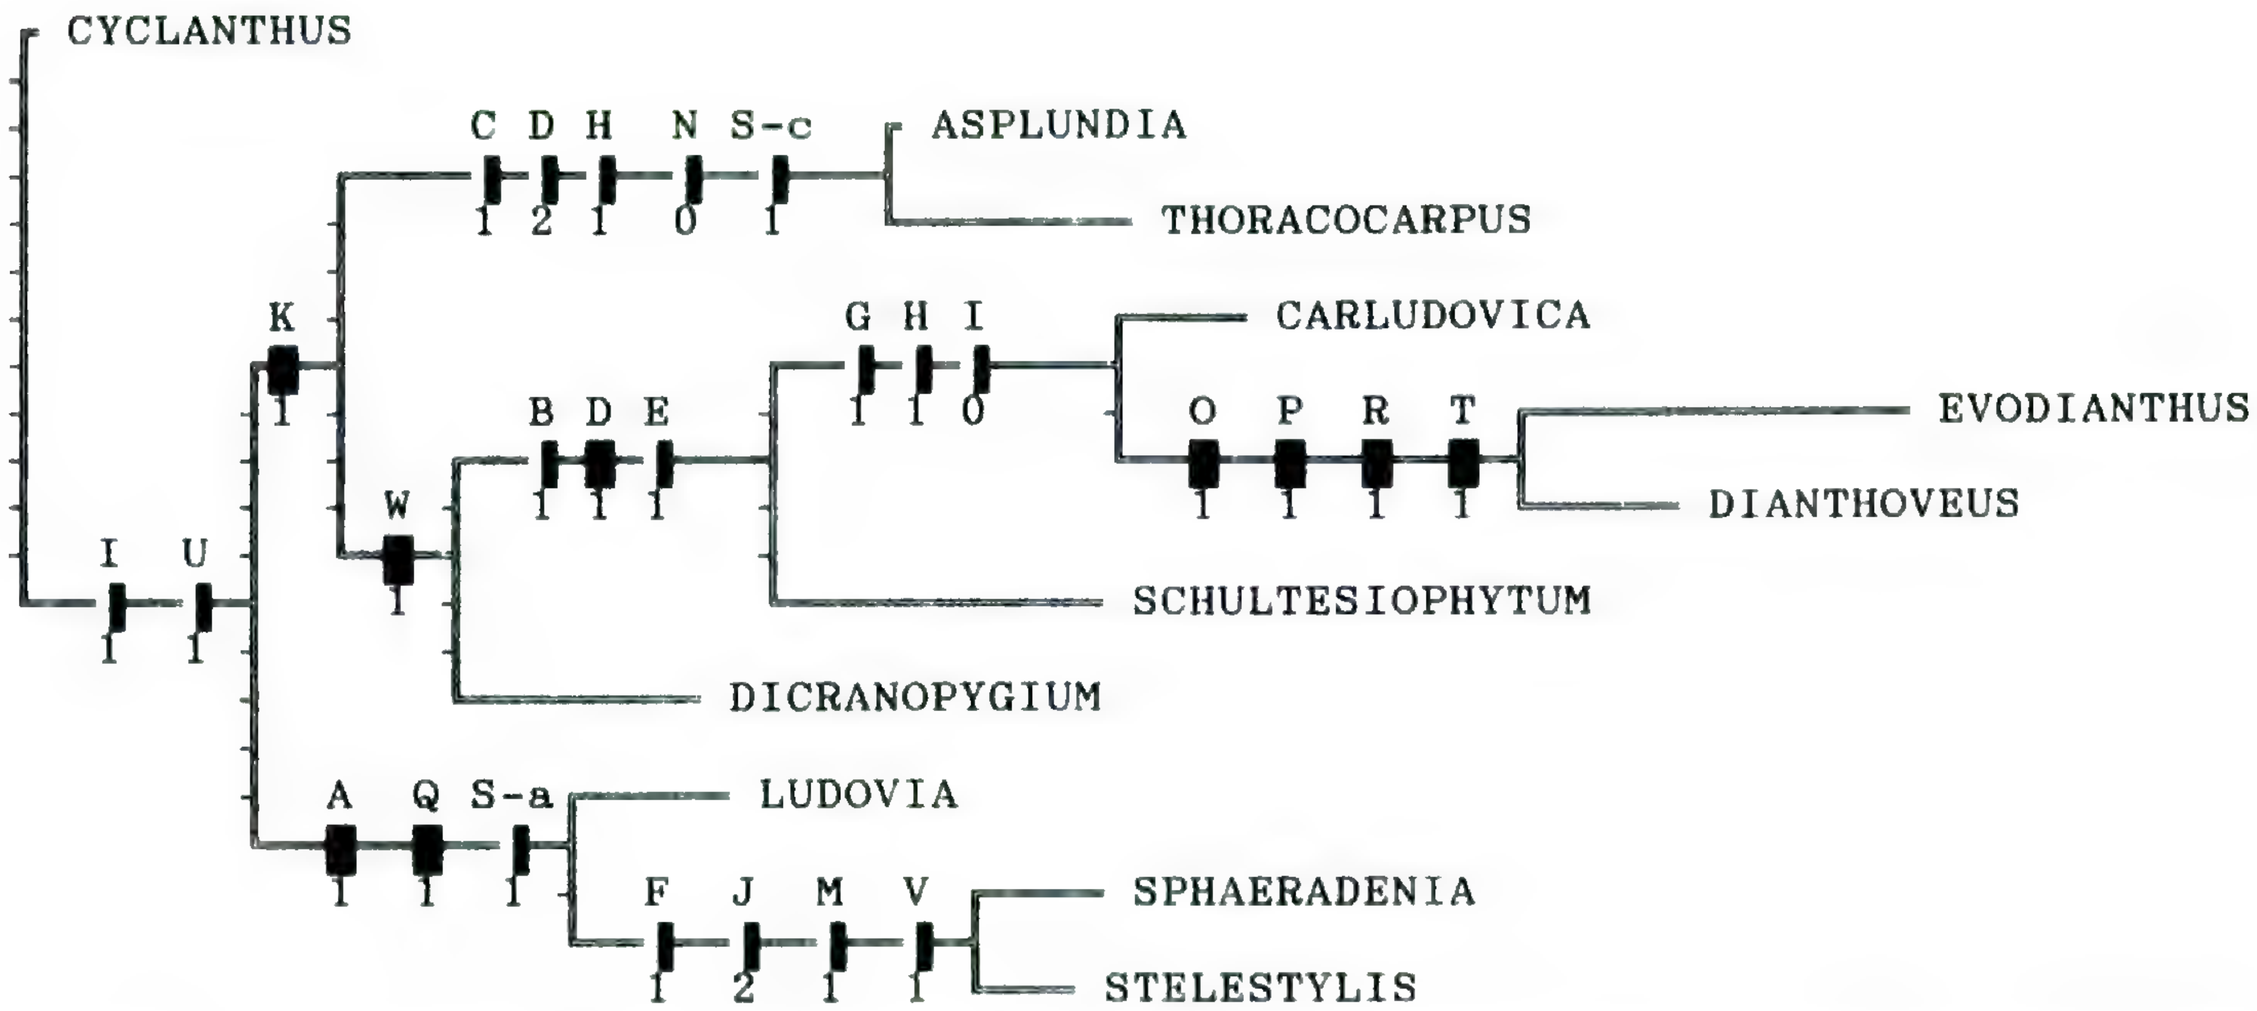

FIGURE 11. Cladogram of the Cyclanthaceae. Wide bars are uniquely derived and consistent synapomorphies; half-bars are synapomorphies of character states found elsewhere in the family or reversed within the defined group. Letters above bars refer to characters (Table 1), numbers below to character states. Length of terminal clade is directly related to number of apomorphies discovered by analysis. Length = 48; consistency index = 0.604; originally known autapomorphies not included in analysis.

acter problematic; genera of the Carludovicoideae have either orthodistichous (in a few species spirodistichous) or spiral phyllotaxy. The Pandanaceae have tristichous phyllotaxy. For this analysis spiro- and orthodistichy were both subsumed under the category "distichous," and phyllotaxy was coded as having only two states. The terminal inflorescences of *Cyclanthus* seem well supported as ancestral; terminal inflorescences are the rule in Araceae (Ray, 1987 and pers. comm.) and in Pandanaceae (Tomlinson & Wilder, 1984) and are characteristic of the "primitive" coryphoid palms. In palms, however, terminal inflorescences are never evicted by axillary shoots (Tomlinson & Wilder, 1984). States for seed characters were coded directly from *Cyclanthus* as ancestral; the similarity of seeds of *Cyclanthus*, *Dicranopygium*, and *Ludovia* with those of some members of the Pandanaceae is one of the main features that Harling (1958) saw as indicating a close relationship between Pandanaceae and Cyclanthaceae.

The branched order of character states for "habit" (Table 1) is rationalized by the observation that variable taxa almost always include terrestrial members. It then seems unlikely that any nonterrestrial form was derived one from another.

RESULTS AND DISCUSSION

From our data matrix (Table 2), PAUP found five trees with 49 steps and a single most parsimonious cladogram with 48 steps (Fig. 11). A sister-group relationship between *Dianthoveus* and *Evodianthus* is supported by all of these analyses. Furthermore, when the data matrix is changed to accommodate different possibilities for states coded as "missing" or different interpretations of problematic characters for the hypothetical ancestor, such as fruit fusion and phyllotaxy, this relationship remains unchanged even when the overall topology changes.

The highly corroborated sister-group relationship between *Evodianthus* and *Dianthoveus* allows a rational discussion of homologies of the unusual staminate flowers in the new genus. On the basis of our hypothesis (Fig. 11), *Dianthoveus* appears to retain more relatively primitive character states than *Evodianthus*, such as the terrestrial (vs. climbing) habit. The moderately flattened seeds are also relatively primitive as compared with the strongly flattened seeds of *Evodianthus*. The laminar-apiculate anther appendages of *Dianthoveus* could be symplesiomorphous with those of *Schultesiophytum*, but that assumption would require an additional step; it is more parsimonious to assume that this kind of anther evolved independently in the two genera. The biseriate perianth of *Evodianthus*—an apomorphy for *Evodianthus* not included in the analysis—appears to be derived within the family.

From this basis we can argue that the inner cycle of the biseriate perianth of *Evodianthus* might be an elaboration of the unusual papillate receptacle of *Dianthoveus*. By this hypothesis, the lobes of the inner perianth of *Evodianthus* are not appendicular organs (leaf homologues), but rather

emergences, equivalent developmentally to the papillae, which compose cupules in *Dianthoveus*.

In all cases, regardless of coding, eglandular staminate tepals appear to have arisen twice within the Carludovicoideae—in *Dicranopygium* subgenus *Gleasonianthus* and in *Dianthoveus*. However, according to Harling (1958; see also Wilder, 1978), the eglandular tepals of subgenus *Gleasonianthus* are not "real perianths," but rather are homologous with stamen filaments; he found that lobes of this "false perianth" sometimes bear reduced anthers. In addition, the filaments of anthers in subgenus *Gleasonianthus* are somewhat flattened and acute, resembling the lobes of the false perianth. In *Dianthoveus* we see no equivalent basis for hypothesizing a staminodial nature for the eglandular tepals. We found none with reduced anthers, and they certainly bear no resemblance to filaments of stamens (*Dianthoveus* lacks filaments). Based on their position, they appear simply to be homologous with the glandular outer whorl of the biseriate perianth of *Evodianthus* and the "real perianth" of other Cyclanthaceae. Under this reasoning, the eglandular tepals of *Dianthoveus* are similar to those of *Dicranopygium* subgenus *Gleasonianthus* only by convergence.

Conclusion

Before our cladogram or any other is presented as a phylogeny for the family, several of the characters and character states need to be re-evaluated and the hypothesis tested with additional characters. For example, the character of spathe position, crucial for placing *Dicranopygium* in the clade definied by clustered spathes, is somewhat subjective. The spathes of *Carludovica*, *Schultesiophytum*, and *Dianthoveus* are not much closer together than many species outside the clade. Which other, if any, multistate characters (e.g., seed shape) might logically be ordered? One also wonders if characters such as inflorescence position and phyllotaxy, which seem to encompass a large suite of characters, should be given extra weight or broken into several characters. All of this needs to be evaluated within the context of a hypothetical ancestor postulated on the basis of taxa outside the Cyclanthaceae.

Although a close relationship between *Dianthoveus* and *Evodianthus* was suggested initially by the observation that only these two have scabrous leaves, a phylogenetic analysis using parsimony demonstrates the hypothesis as supported by numerous characters. It also provides a logical basis for suggesting the evolutionary homologies of the unusual floral features of the new genus, in particular, the papillate receptacle (possibly homologous with the inner perianth of *Evodianthus*), the laminar apiculate anthers (evolved in parallel to those of *Schultesiophytum*), and the eglandular tepals (convergent with those of *Dicranopygium* subgenus *Gleasonianthus*).

ANATOMIA REPRODUCTIVA DE *LACANDONIA SCHISMATICA* (LACANDONIACEAE)[1]

J. Márquez-Guzmán,[2] *M. Engleman,*[3] *A. Martínez-Mena,*[2] *E. Martínez*[4] *y C. Ramos*[2]

Resumen

Lacandonia schismatica es una familia, género, y especie nuevos para la ciencia. El carácter más conspicuo lo constituye la posición del androceo en el centro de la flor, rodeado por el gineceo apocárpico. Tal disposición no había sido mencionada antes para angiospermas. El androceo está formado por tres anteras (a veces cuatro) biloculares con dehiscencia introrsa. El gineceo es apocárpico. Cada carpelo contiene un solo óvulo sésil, basal, anátropo, y bitégmico; el tegumento interno forma el micrópilo. El endospermo es de tipo nuclear. El embrión en la semilla madura es poco desarrollado. El fruto es indehiscente.

Abstract

Lacandonia schismatica comprises a new family, genus, and species. Its most conspicuous character is the central position of the androecium, surrounded by the apocarpous gynoecium. This arrangement has not been recorded before for angiosperms. The androecium consists of three (sometimes four) bilocular anthers with introrse dehiscence. The gynoecium is apocarpic. Each carpel contains a single ovule that is sessile, basal, anatropous and bitegmic; the inner integument forms the micropyle. The position of the style on the ovary changes during development. The endosperm is of the nuclear type. The embryo of the mature seed is poorly developed. The fruit is indehiscent.

La nueva familia Lacandoniaceae del orden Triuridales (Martínez y Ramos, 1989) es afín a Triuridaceae Gardner (Maas y Rübsamen, 1986) pero se diferencia por el gineceo que rodea al androceo y la dehiscencia introrsa de las anteras.

La inversión de posición de los órganos reproductores fue lo suficientemente interesante para iniciar los estudios estructurales. A continuación se presentan los primeros resultados al respecto.

Materiales y Metodos

Se estudió material de dos colectas (E. Martínez M. *19310* y *21822*) de *Lacandonia schismatica* E. Martínez y C. H. Ramos. Se fijaron muestras de botones florales, flores, y frutos en diversas etapas de desarrollo en el sitio mismo de colecta (selva Lacandona, Chiapas, México), y las muestras se trasladaron al laboratorio para su procesamiento posterior.

Se usaron tres fijadores diferentes: a) FAA (formalina, ácido acético, etanol al 70%; 5 : 5 : 90); b) glutaraldehido al 5% en amortiguador de fosfatos 0.1 M pH 6.8 con sacarosa al 0.25 M; c) glutaraldehido al 5% + paraformaldehido al 4% en amortiguador de S colidina 0.1 M pH 7.2.

Después de la fijación algunas muestras fueron deshidratadas en series graduales de alcohol etílico

y otras en acetona, y se incluyeron en parafina, plástico de JB4 o metacrilatos.

Para seccionar las muestras incluídas en parafina se utilizó un micrótomo rotatorio, y para las incluídas en resinas sintéticas un ultramicrótomo con navajas de vidrio. Los cortes de 1 a 2 μm se tiñeron con safranina/verde rápido o con azul de toluidina.

Resultados

Posición de los verticilos florales. El verticilo más externo está constituído por seis tépalos papilosos. La posición del androceo en el centro de la flor con el gineceo apocárpico alrededor se muestra claramente en cortes longitudinales de botones florales (Fig. 1). La continuidad de la epidermis que se observa desde la base de las anteras hasta el receptáculo no deja dudas sobre su posición central.

Androceo. Se observó que las anteras se desarrollan y maduran antes que los carpelos y persisten, sin caerse, después de que los frutos se han dispersado.

El androceo está formado por tres anteras (una flor entre cincuenta y cuatro observadas poseía cuatro anteras). Las anteras son biloculares, y la pared de la antera inmadura está formada por tres capas: la epidermis, el endotecio, y el tapetum (Fig. 2). El tapetum desaparece en la antera madura (Figs. 3, 4). Los estambres no poseen vascularización. El grano de polen maduro posee tres células (Fig. 5). La dehiscencia de las anteras es introrsa (Fig. 6).

Gineceo. El gineceo es apocárpico. La orientación de los carpelos es variable, de tal manera que la mayoría de ellos no tiene el estilo en el lado orientado hacia los estambres, en el centro del receptáculo. El estilo parte de la región superior del carpelo en el mismo lado que corresponde al hilo de la semilla (Fig. 8).

Cada carpelo contiene un solo óvulo sésil, basal, anátropo (Fig. 7), y bitégmico; ambos tegumentos son biestratificados, y el interno forma el micrópilo. El desarrollo del endospermo es de tipo nuclear, y el endospermo maduro posee células de paredes gruesas (Fig. 9). El embrión más desarrollado que se ha observado posee dos células; el cigoto se dividió transversalmente (Fig. 10). La cubierta seminal tiene una capa con inclusiones en forma de partículas.

El fruto es indehiscente. La epidermis del fruto posee células globosas cuando está en antesis.

Discusion

Las estructuras reproductoras de *Lacandonia schismatica* son comparables a las mencionadas por Tomlinson (1982) y por Maas y Rübsamen (1986) para la familia Triuridaceae.

La dehiscencia introrsa de las anteras es una característica que define esta especie. Sin embargo, el hecho más conspicuo, y nunca antes mencionado para Triuridaceae u otras angiospermas, es la posición central del androceo con respecto al gineceo (Cronquist, 1981). Esta disposición se observa más claramente en cortes medianos de botones florales inmaduros.

La continuidad celular, en especial la epidérmica, que se observa con los tejidos del centro del receptáculo es la prueba más fehaciente de su posición. Sin embargo muchos detalles de la formación del óvulo y la semilla se desconocen y aun no se sabe que tipo de embrión representan. La germinación no ha sido observada. Se pone de manifiesto la necesidad de realizar estudios embriológicos, además de estudios anatómicos comparativos de especies de la familia Triuridaceae. Tales resultados contribuirán a ubicar filogenéticamente a esta familia y dar luz sobre el significado evolutivo de la inversión en la posición de los órganos reproductores.

LACANDONIACEAE (TRIURIDALES): UNA NUEVA FAMILIA DE MEXICO[1]

Esteban Martínez[2]
y Clara Hilda Ramos[3]

Resumen

Se describen una familia, un género y una especie de Triuridales nuevos para la ciencia. La nueva familia es afín a Triuridaceae Gardner, de la cual se diferencia por el gineceo rodeando al androceo; posición insólita que se describe por primera vez, y la dehiscencia introrsa de las anteras. Este es el primer registro del orden para México.

Abstract

A new family, genus, and species are described. The new family is placed in Triuridales. It differs from Triuridaceae by the unexpected and unknown elsewhere position of the gynoecium, which surrounds the androecium, and by the introrsely dehiscent anthers. This is the first record of the order for Mexico.

Entre las plantas colectadas para el proyecto Flora Mesoamericana (CONACyT PCECBEU-001109), se encontraron plantas del orden Triuridales que consideramos son familia, género, y especie nuevos para la ciencia y se describen a continuación:

Lacandoniaceae E. Martínez et C. H. Ramos, fam. nov. ordinis Triuridalium.

Flores hermaphroditi gynoecio apocarpo androecium cingenti, tribus staminibus centralibus antheris biloculatibus dehiscentia introrsa, apertura singularis.

Flores hermafroditas; gineceo apocárpico rodeando al androceo, tres estambres centrales y anteras biloculares con una sola línea de dehiscencia introrsa.

Lacandonia E. Martínez et C. H. Ramos, gen. nov.

Herbae saprophyticae, albidae, aphyllae. Caules simplices. Rhizoma glabrum horizontale radicibus pubescentibus. Inflorescentia racemosa. Flores hermaphroditi. Tepala (4–)6, apicibus caudatis, dense papillosa. Gynoecium apocarpum, carpellis 60–80. Styli subapicales. Stamina (2–)3(–4), centralia, marcescentia, gynoecium propinqua, antherae bilocularia introrsa, lobis 2(–3) confluentibus longitudinaliter dehiscentibus. Fructus aggregatus e multis acheniis constatus.

Hierbas saprofíticas, afilas, blanquecinas. Rizoma horizontal de crecimiento indefinido, con raíces fibrosas y esparcidamente pubescentes. Tallos aéreos simples, glabros. Inflorescencia racemosa, bracteada, de crecimiento simpodial; pedicelos ascendentes. Flores perfectas; tépalos (4–)6, densamente papilosos cuando frescos, cada uno con una cauda linear-laminar en el ápice. Gineceo y androceo sobre un receptáculo deprimido centralmente, con los carpelos rodeando al androceo. Gineceo con 60–80 carpelos papilosos; estilo subapical. Estambres (2–)3(–4), centrales, persistentes, insertos en el borde de la depresión del receptáculo; anteras biloculares con 2(–3) lóbulos, introrsas, una sola línea de dehiscencia longitudinal, polen intectado, inaperturado, verrugado. Fruto poliaquenio.

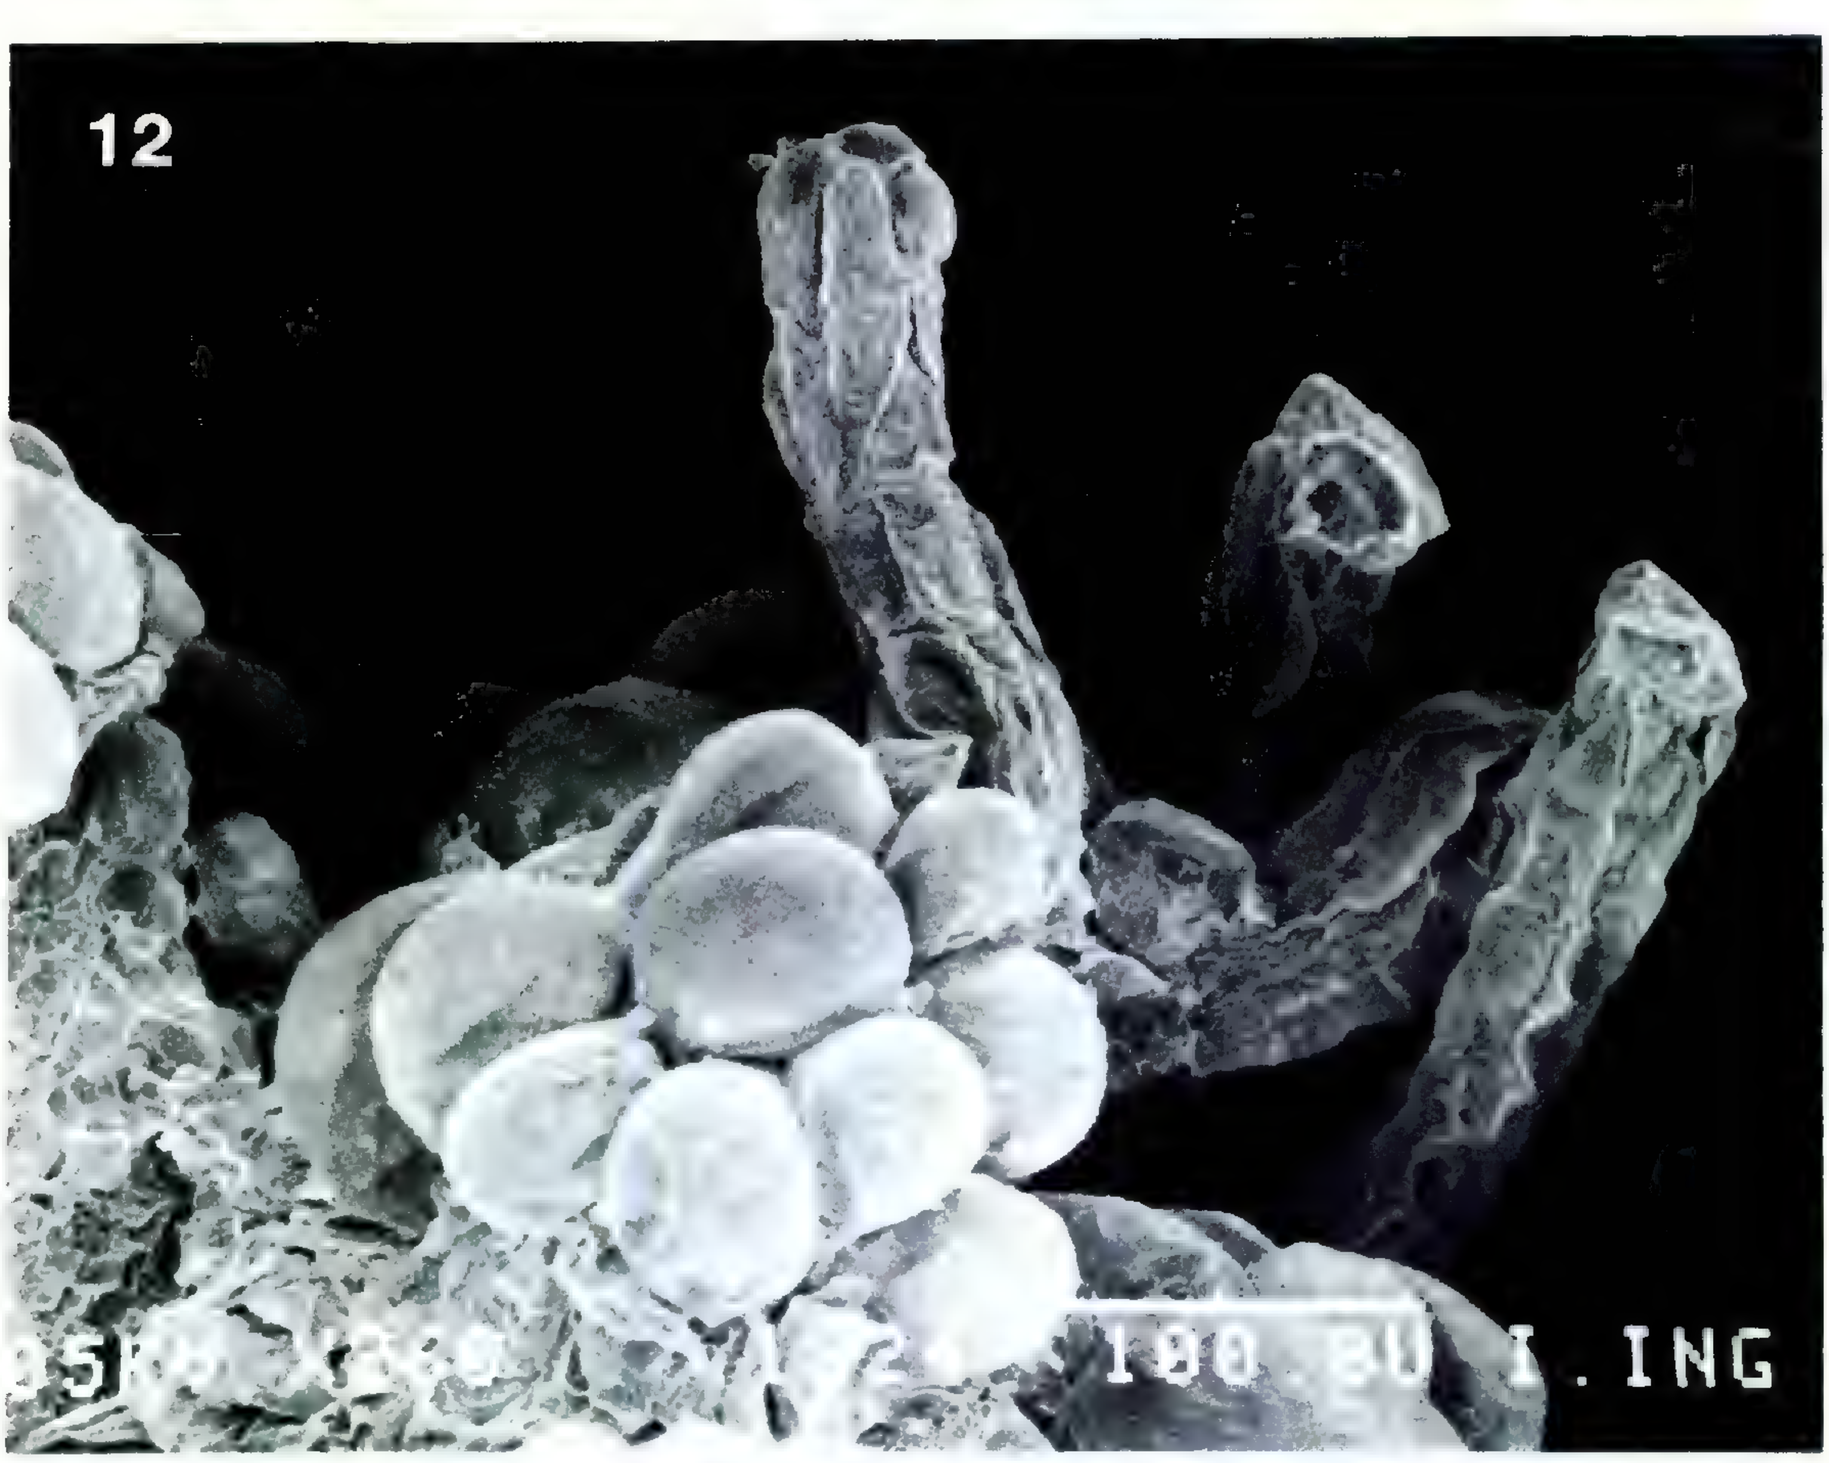
FIGURAS 9, 10.—9. Vista posterior de la flor en la que se observan los haces vasculares que divergen del pedicelo hacia los tépalos. A contraluz se distinguen los frutículos (material fijado). Fotografía de Alejandro Martínez Mena.—10. Vista de la flor. Se observan la apariencia papilada y los tres estambres centrales rodeados por los ovarios. Fotografía de Ricardo Peralta y Fabi.



FIGURAS 11, 12.—11. Apice de un tépalo con la cauda erecta. Se distinguen las papilas.—12. Frutículo. Se ven las papilas y el estilo persistente. Fotografías de Ricardo Peralta y Fabi.

cauda 1(–2) mm longa et 0.1 mm lata. Gynoecium carpellis obovoideis, dense papillosis. Stamina 3, filamentis 0.1 mm longis, antheris circa 0.3 mm longis, 0.1 mm latis. Achenia obovata, 0.45–0.6 mm longa, 0.28–0.35 mm lata, dense papilloso.

Hierbas hasta de 9 cm de alto. Rizoma glabro, 0.2–0.3 mm de diámetro, con raíces filiformes, 1.0–3.5 cm de largo, ca. 0.1 mm de diámetro. Tallos rollizos, usualmente 3–5 cm de largo, 0.4–0.5 mm

de diámetro. Inflorescencia hasta de 4 cm de largo con brácteas trilobadas, 0.6–1.0 mm de largo, 0.4–0.8 mm de ancho en la base, subamplexicaules; pedicelo 3–4(–7) mm de largo. Flores (1–)3–7(–13), en espiral, 3.8–4.1 mm de diámetro; tépalos 6, deltoides, fusionados desde la base hasta la parte media, ca. 1 mm de largo, 0.9–1.1 mm de ancho, las caudas ca. 1(–2) mm de largo y 0.1 mm de ancho. Carpelos obovoides, 0.48–0.6 mm de largo, 0.2–0.25 mm de ancho; estilo papilado 0.2–0.25 mm de largo; estigma de color oscuro, ca. 0.04 mm de largo y ancho. Estambres 3, con los filamentos de 0.1 mm de largo; anteras sub-basifijas, ca. 0.3 mm de largo y 0.1 mm de ancho. Aquenios obovoides 0.45–0.6 mm de largo, 0.28–0.35 mm de ancho, con el estilo persistente, papilosos, ligeramente esponjosos; semilla 0.4–0.5 mm de largo, 0.2–0.25 mm de ancho, pardo oscura.

Distribución y hábitat. Sólo conocida de la localidad tipo, en selva alta subperennifolia inundable de *Calophyllum brasiliense* Camb. con *Terminalia amazonia* (J. Gmelin) Exell y *Cryosophila argentea* Bartlett. Muchos de los elementos de esa zona son de nuevo registro para la región, como *Chionanthus domingensis* Lam., *Guettarda tikalana* Lundell, *Schizaea poeppigiana* Sturm, *Actinostachys germanii* Fée, y *Guzmania lingulata* (L.) Mez var. *minor* (Mez) L. B. Smith & Pittend, entre otros. Vive sobre substratos de materia orgánica muy húmedos, pero no inundados, en lugares muy sombreados con poca oscilación de temperatura. La localidad tipo se sitúa en el exterior del borde de la reserva de Montes Azules, área que se talará para crear potreros.

Fenología. Florece todo el año si las condiciones de humedad son adecuadas. Muy abundante en noviembre y diciembre, después de la temporada de lluvias.

Material adicional examinado. MEXICO. CHIAPAS: Mpio. Ocosingo, Crucero Corozal, 170 km al SE de Palenque, camino a Boca Lacantum, sobre la carretera fronteriza del sur, 15 Sept. 1985, *E. Martínez S. 13996* (MEXU); 6 Nov. 1985, *Martínez 14982* (MEXU); 29 mayo 1987, *Martínez 21381* (MEXU); 27 Ago. 1987, *Martínez 21822* (MEXU); 10 Dic. 1987, *Martínez 21921* (MEXU).

Lacandoniaceae comparte con Triuridaceae los siguientes caracteres: gineceo apocárpico, óvulos anátropos, polen inaperturado, flores trímeras, tépalos con apéndices, hábito saprofítico, y micorrizas endotróficas. Sin embargo, difiere por: a) La disposición espacial de los órganos reproductores, con los estambres ocupando la parte central de la flor. Tal posición no había sido contemplada antes para angiospermas (A. P. de Candolle, 1813; Hutchinson, 1959; Takhtajan, 1969; Cronquist, 1981). b) La dehiscencia introrsa de las anteras, extrorsa en Triuridaceae (Tomlinson, 1982; Maas & Rübsamen, 1986).

El análisis cromatográfico comparativo entre *Triuris* sp. y *Lacandonia schismatica* indica claras diferencias en el tipo de metabolitos secundarios (G. Delgado, inéd.).

Cronquist (1981) colocó en el orden Triuridales a las familias Petrosaviaceae Hutchinson y Triuridaceae Gardner. Petrosaviaceae comparte con Lacandoniaceae la dehiscencia introrsa de las anteras, el hábito herbáceo, y la micotrofía, pero difiere por presentar estomas, tépalos en dos series, carpelos fusionados basalmente con muchos óvulos, nectarios septales, y granos de polen monosulcados.

Dahlgren et al. (1985) consideraron en Triuridales únicamente a Triuridaceae.

La relación espacial que presentan los órganos reproductores es difícil de explicar a la luz de los conocimientos actuales. En ausencia de información previa, se están llevando a cabo estudios anatómicos (Márquez-Guzmán et al., este tomo) y fitoquímicos que ayuden a esclarecer su posición taxonómica.

El nombre genérico está dedicado a la región Lacandona, asiento del pueblo Lacandón, en el estado de Chiapas, México. El epíteto específico se refiere a los problemas que origina su morfología en la sistemática.

SYSTEMATICS OF THE AMAZON LILIES, *EUCHARIS* AND *CALIPHRURIA* (AMARYLLIDACEAE)[1]

Alan W. Meerow[2]

ABSTRACT

Eucharis and *Caliphruria* are closely related, neotropical genera of petiolate-leaved, white-flowered Amaryllidaceae found in the understory of primary tropical rain forest. Together with the Peruvian endemic *Urceolina*, *Eucharis* and *Caliphruria* form a monophyletic group within "infrafamily Pancratioidinae" on the basis of leaf and seed morphology and ecological specialization. Seventeen species and two natural hybrids within two subgenera are recognized in *Eucharis*. *Eucharis*, marked by its crateriform or campanulate flowers, curved perianth tube, pigmented androecium usually developed into a staminal cup, and unicellular stigmatic papillae, is distributed from Guatemala to Bolivia, chiefly in the western Amazon basin and adjacent lower slopes of the eastern Andes. Subgenus *Heterocharis* represents three relict species and two natural hybrids with many ancestral characters of the genus. *Caliphruria* (four species, three of which are endemic to Colombia) has funnelform flowers, straight perianth tube, reduced staminal connation, and multicellular stigmatic papillae. Cladistic relationships support the monophyly of *Eucharis*, *Caliphruria*, and *Urceolina* as a unified group. The most parsimonious cladograms suggest that *Eucharis* is paraphyletic if subg. *Heterocharis* is included. An alternative hypothesis of generic relationships is tested, and proves less parsimonious. Recognizing the close phenetic relationship of subg. *Heterocharis* to the rest of *Eucharis*, the high levels of homoplasy within the cladogram, and ambiguity caused by missing character state data, a less parsimonious phylogeny is accepted as the basis for classification. Keys and descriptions are provided for all species of *Eucharis* and *Caliphruria*. *Eucharis caucana*, a novel hexaploid ($2n = 138$) species, is described from Colombia.

The closely related genera *Eucharis* Planchon & Linden and *Caliphruria* Herbert (Amaryllidaceae), the Amazon lilies, comprise respectively 17 and 4 species of bulbous, rain forest geophytes adapted to the low light conditions of the forest understory. Together with the Peruvian endemic *Urceolina* Reichenb., nom. cons., *Eucharis* and *Caliphruria* form a monophyletic group delimited by petiolate leaves with distinctive cuticular striation; a turgid seed with a lustrous, usually black testa; and complete fidelity to the rain forest understory niche. The species are distributed from Guatemala to Bolivia. The major center of distribution for *Eucharis* is in the western Amazon basin (inclusive of major tributary systems, e.g., the Napo, Pastaza, and Huallaga) and the adjoining lower slopes of the eastern Andean cordillera. With the exception of single Peruvian species, *Caliphruria* is restricted to the Cordillera Occidental and Cordillera Central of Colombia. The species of both genera are nowhere abundant, and are found growing only in primary, rarely secondary, forest from

ANN. MISSOURI BOT. GARD. 76: 136–220. 1989.

ca. 50 to 1,800 (rarely to 2,000) m elevation on soils of high fertility. Large-scale deforestation has proven catastrophic to these plants, which are unable to adapt to the higher light intensity of the clearings and soon perish. At least several species are probably extinct, and this number will only increase with time as rain forest destruction continues unabated.

The Amazon lilies are marked by their evergreen, petiolate leaves; white, often pendent, sometimes fragrant flowers with a frequently conspicuous staminal cup or false corona formed by the basal connation of the staminal filaments; obtusely trilobed stigma; and large, turgid, globose or ellipsoid seeds with a black, brown, or metallic blue testa. *Eucharis amazonica* Linden ex Planchon is widely known in horticulture, often erroneously as *E. grandiflora* Planchon & Linden (Meerow & Dehgan, 1984a). Neither genus has ever been critically treated in the taxonomic literature. Baker (1888) provided a key and descriptions for all species known at the time in his *Handbook of the Amaryllideae*, and Macbride (1936) treated the known Peruvian species of *Eucharis* for the *Flora of Peru*. Though species of *Eucharis* have continued to be described well into the present decade, the delimitation of these species from previously described taxa has consistently remained vague. No assessments of variation at either the population or species level have been attempted.

As two of only three genera of neotropical Amaryllidaceae (the other being the related *Urceolina*) exhibiting complete fidelity to a primary rain forest niche, systematic understanding of *Eucharis* and *Caliphruria* offers important information relating to the evolution of the pancratioid Amaryllidaceae ("infrafamily Pancratioidinae" Traub (1957, 1963)),[3] centered in the central Andean region of South America.

No taxonomic scheme can encompass all of the information about the group of organisms under study (Holsinger, 1984, 1985; Ornduff, 1969; Raven, 1976). In genera such as *Eucharis* and *Caliphruria*, rare in the wild and often accessible only with difficulty, and which often exhibit cryptic patterns of variation, this observation becomes much more acute. By accumulating data from as many diverse sources as possible, I have attempted to construct an evolutionary systematic classification of the Amazon lilies that is both practical yet reflects their evolutionary relationships as accurately as these data allow.

Materials and Methods

FIELD STUDIES

Fieldwork was conducted in Peru and Ecuador in July–August 1982, and in Colombia and Ecuador in July–August 1984. Herbarium specimens and living material were collected, and ecological observations of natural populations were made.

ANATOMICAL STUDIES AND SCANNING ELECTRON MICROSCOPY (SEM)

Material was prepared and examined as described in Meerow (1987c).

CLADISTIC ANALYSES

Cladistic analyses were run using PAUP version 2.4.1 by David L. Swofford (Illinois Natural History Survey). All species (and two subspecies) of *Eucharis* and *Caliphruria* (22 evolutionary units, EUs) excluding hybrid taxa were analyzed using forty-one characters (Tables 1–3). For analyses with PAUP, global branch swapping with the MULPARS option was used in all searches for the most parsimonious cladograms. Because of the unavailability of material, all described species of *Urceolina* could not be included in the analysis. *Urceolina* was therefore entered in the analysis at the generic level, with character state data drawn from study of living material of *U. microcrater* Kränzlin and specimens of *U. urceolata* (Ruíz & Pavón) Green and *U. ayacucensis* Ravenna. Character states were determined from examination of living and dried material. Character state polarities were assessed via outgroup comparison (Maddison et al., 1984; Watrous & Wheeler, 1981). Selection of outgroups is discussed later with the results of the analyses.

Of the 41 characters used in the analysis, 23 were simple, two-state characters. The 18 remaining multistate characters (14 three-state, 2 four-state, 1 five-state, and 1 six-state) were treated in preliminary analyses as unordered (Fitch, 1971; Hartigan, 1973) using this option of PAUP, rather than attempting to create any a priori transformation series. This resulted in a preponderance of weak monophyletic groups based on single apomorphies and/or character state reversals, as well as unresolved polytomies among many terminal taxa. In the analyses presented, 11 of these characters were treated as ordered transformation series (the remaining seven as unordered), with one

[3] This unofficial rank is used in this paper as a label of convenience, since there is as yet insufficient evidence to recognize this group of genera as a distinct subfamily.

(number 41, chromosome number) coded in additive binary. Justification for these treatments is discussed with the results of the analyses. Multistate characters were adjusted to equal weight with two-state characters using the "weights scale" option of PAUP. Additionally, an alternative hypothesis of generic relationship was tested by submitting a user-coded tree topology to PAUP for analysis.

HERBARIUM STUDY AND LIVING MATERIAL

Loans or gifts of herbarium specimens were received from the following herbaria: AAU, B, BM, COL, CUVC, F, FTG, G, GB, GH, GOET, HUNT, K, LE, M, MG, MICH, MO, MPU, NA, NY, OXF, P, QCA, S, SEL, SP, U, UC, US, VEN.

Neither *Eucharis* nor *Caliphruria* is well represented in herbarium collections, and critical morphological characters are often obscured by the drying process. Consequently, a living collection of over 100 accessions representing fifteen species and several hybrids was accumulated from botanical gardens, individuals, and field collections by myself and various colleagues. Vouchers for living material are listed with specimens cited for each species.

Taxonomic History

Herbert (1844) described the new genus *Caliphruria* from collections made in New Granada (Colombia) near Guaduas by Hartweg, placing *Caliphruria* in the "section" Pancratiformes of "suborder" Amaryllideae. Genera of this "section" were united by the single character of staminal connation. The small, white, funnelform flowers were marked by the presence of a bristle or slender tooth at either side of the filament. Herbert (1844) made no mention of basal connation of the filaments. The orthography of the name, a single "l" in the Greek stem "calli-," was emended by subsequent workers (e.g., Baker, 1877), but was returned to Herbert's original by Meerow & Dehgan (1984b).

Planchon & Linden (1852) introduced another new pancratioid genus, *Eucharis*. The first species described, *E. candida* Planchon & Linden, collected in New Granada by M. Schlim, was characterized by its crateriform flowers with a conspicuous staminal cup and a widely spreading perianth limb. If these authors were aware of *Caliphruria*, they did not note any relationship between it and *Eucharis*.

Bentham & Hooker (1883) placed *Caliphruria* and *Eucharis* in the tribe *Cyathiferae*. *Caliphruria subedentata* Baker was combined with *Eucharis* in their treatment, while *C. hartwegiana* Herb. was retained. Baker (1888) accepted this treatment, yet described another new species as *C. tenera*. He described *Caliphruria* as "nearly allied to *Eucharis*."

Baillon (1894) described the species *C. castelnaeana* and declared it precisely intermediate between *Caliphruria* and *Eucharis*. He further suggested that *Eucharis* should be treated as a section of *Caliphruria*. Macbride (1931) later transferred *C. castelnaeana* to *Eucharis*.

Nicholson (1884) transferred *C. hartwegiana* (the type species of *Caliphruria*) to *Eucharis*, ignoring the former's nomenclatural priority. Traub (1967) made the formal transfer of the remaining species of *Caliphruria*, *C. tenera* Baker, to *Eucharis* and combined the monotypic genus *Plagiolirion* Baker with *Eucharis*. He had previously listed *Caliphruria*, *Plagiolirion*, and *Mathieua* Klotzsch (another monotypic genus) as synonyms for *Eucharis* in his *Genera of the Amaryllidaceae*, citing Baillon (1894) as a "special reference" (Traub, 1963: 74). The nomenclatural priority of *Caliphruria* Herbert was overlooked. No proposal for the conservation of *Eucharis* Planchon & Linden over *Caliphruria* Herbert has ever been proposed previous to that of Meerow & Dehgan (1984b).

Traub (1971) later combined *Eucharis* with *Urceolina*, a small Andean genus with petiolate leaves and markedly urceolate, brightly colored flowers. He designated five subgenera: *Urceolina*, *Eucharis*, *Caliphruria*, *Mathieua*, and *Plagiolirion*. Traub (1971) offered no explanation for the combination of *Eucharis* and *Urceolina*, but presumably his decision was prompted in part by reports in the literature of two intergeneric hybrids between *Eucharis* and *Urceolina*: ×*Urceocharis clibranii* Masters, an artificial hybrid, and ×*U. edentata* C. H. Wright, putatively discovered in Peru. *Plagiolirion* and *Mathieua* are monotypic genera allied to *Hymenocallis* Salisb. and *Stenomesson* Herbert respectively (Meerow, 1987a).

Vegetative Morphology

BULBS

The globose or subglobose bulbs of *Eucharis* and *Caliphruria*, composed of concentric and modified leaf bases (scales), are characteristic of most members of the Amaryllidaceae. The bulbs are sympodial in growth habit (Arroyo, 1984). The outer scales of *Eucharis* and *Caliphruria* bulbs are modified into an either brown or tan paper tunic. The bulb scales of most species of *Eucharis*

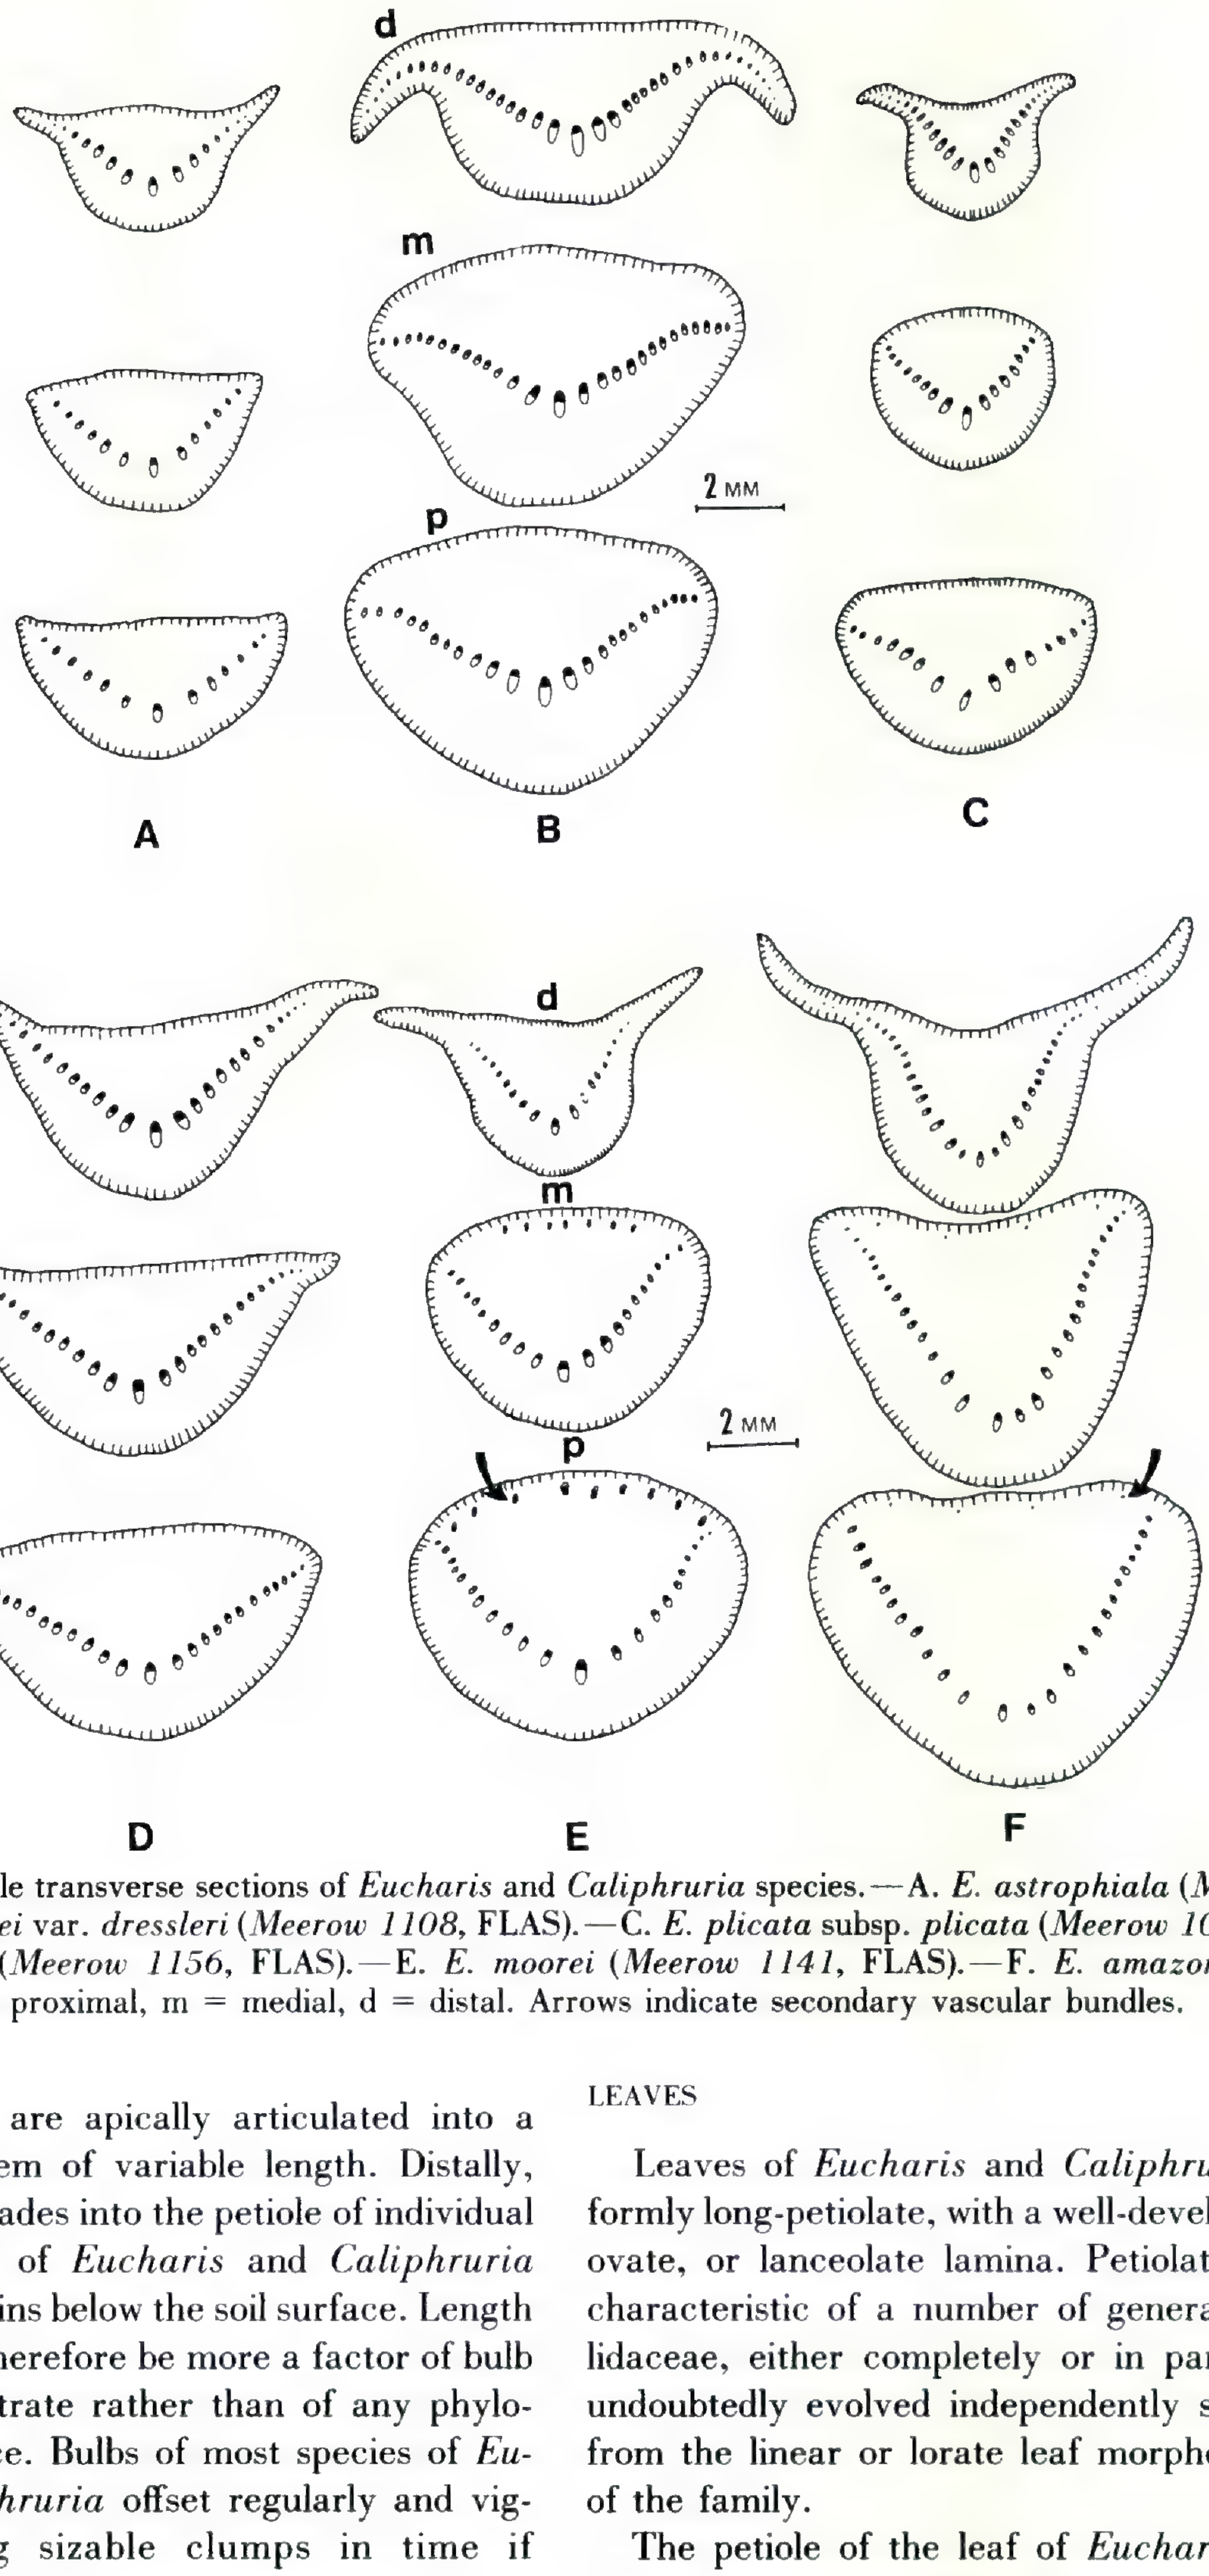

FIGURE 1. Petiole transverse sections of *Eucharis* and *Caliphruria* species.—A. *E. astrophiala* (*Madison 3792*, SEL).—B. *E. bouchei* var. *dressleri* (*Meerow 1108*, FLAS).—C. *E. plicata* subsp. *plicata* (*Meerow 1025*, FLAS).—D. *C. subedentata* (*Meerow 1156*, FLAS).—E. *E. moorei* (*Meerow 1141*, FLAS).—F. *E. amazonica* (*Schunke 14179*, FLAS). p = proximal, m = medial, d = distal. Arrows indicate secondary vascular bundles.

and *Caliphruria* are apically articulated into a neck or pseudostem of variable length. Distally, the pseudostem grades into the petiole of individual leaves. The neck of *Eucharis* and *Caliphruria* bulbs always remains below the soil surface. Length of the neck may therefore be more a factor of bulb depth in the substrate rather than of any phylogenetic significance. Bulbs of most species of *Eucharis* and *Caliphruria* offset regularly and vigorously, forming sizable clumps in time if undisturbed.

LEAVES

Leaves of *Eucharis* and *Caliphruria* are uniformly long-petiolate, with a well-developed elliptic, ovate, or lanceolate lamina. Petiolate leaves are characteristic of a number of genera of Amaryllidaceae, either completely or in part, and have undoubtedly evolved independently several times from the linear or lorate leaf morphology typical of the family.

The petiole of the leaf of *Eucharis* and *Caliphruria* is usually as long or longer than the lamina.

It tends toward subterete cross sections (Fig. 1), rounded abaxially, and flattened adaxially, becoming slightly channeled proximal to the sinus. The petiole is winged proximal to the sinus by attenuation of the lamina. The midrib is pronounced abaxially along the entire length of the lamina, and slightly channeled adaxially, continuous with the petiole.

Leaf shape only rarely provides taxonomically useful information. Length/width ratios are subject to considerable variation even among the leaves of a single bulb. Herbarium specimens will frequently include only a single leaf, with no indication of its developmental age. Taxonomic consistency of leaf shape is exceptional, but useful in the few cases where it occurs. For example, leaves of *E. ulei* Kränzlin are consistently narrowly elliptic. *Eucharis amazonica* (leaf length/width ratio greater than 2) may be delimited from *E. moorei* (Baker) Meerow (l/w less than 2).

The leaves of *Eucharis* and *Caliphruria* are completely glabrous and nonglaucous, with a single exception. *Eucharis bonplandii* (Kunth) Traub, a rare tetraploid species from central Colombia, develops a glaucous bloom that gives the leaf a blue cast in strong light.

The leaf apex of all species is shortly acuminate, the base attenuate. Coarse undulation of the margin will sometimes make the lamina appear cordate at the base. Leaf margins of *Caliphruria* are uniformly nonundulate.

Leaf venation of *Eucharis* and *Caliphruria* is parallelodromous (Hickey, 1973), with a great number of transverse, commissural veins interconnecting the primary vasculature. All species of *Caliphruria* have smooth, nonplicate leaves. *Eucharis* is variable for this character, but the majority of species have plicate leaves.

The adaxial epidermis of most species of both genera is lustrous, dark green; the abaxial surface appears lighter, or silvery green. Only *E. astrophiala* (Ravenna) Ravenna has diverged markedly from the typical morphology and has a uniquely nonlustrous, bullate-pustulate leaf texture.

CUTICLE

Cuticular striation is prominent on the abaxial leaf surfaces of most *Eucharis* and *Caliphruria* species (Figs. 2–6, 8–12). Striae are thickest in *C. subedentata* (Fig. 11). Arroyo & Cutler (1984) recognized eight cuticular sculpturing classes in a survey of 25 genera of Amaryllidaceae. The most common cuticular morphology of *Eucharis* and *Caliphruria* fits their class VII: "thick striae, parallel or not, interlocking, ± transverse."

In a few species of *Eucharis* (*E. amazonica*, *E. moorei* (Fig. 10), *E. bouchei* (Fig. 9)), the striation is much less pronounced. *Caliphruria korsakoffii* (Traub) Meerow (the sole representative of *Caliphruria* outside Colombia) has the most aberrant cuticle morphology (Fig. 12), corresponding more or less to type V of Arroyo & Cutler (1984): "central, thick axial striation with less pronounced striae running from it, directly to anticlinal walls." The adaxial cuticles of *Eucharis* and *Caliphruria* are either smooth or rarely much more finely striate than the abaxial surface, the striations entirely axial in orientation. The adaxial cuticle of *C. korsakoffii* (Fig. 13) has several, thick, transverse striations across each cell, and the epidermis is unusually flat.

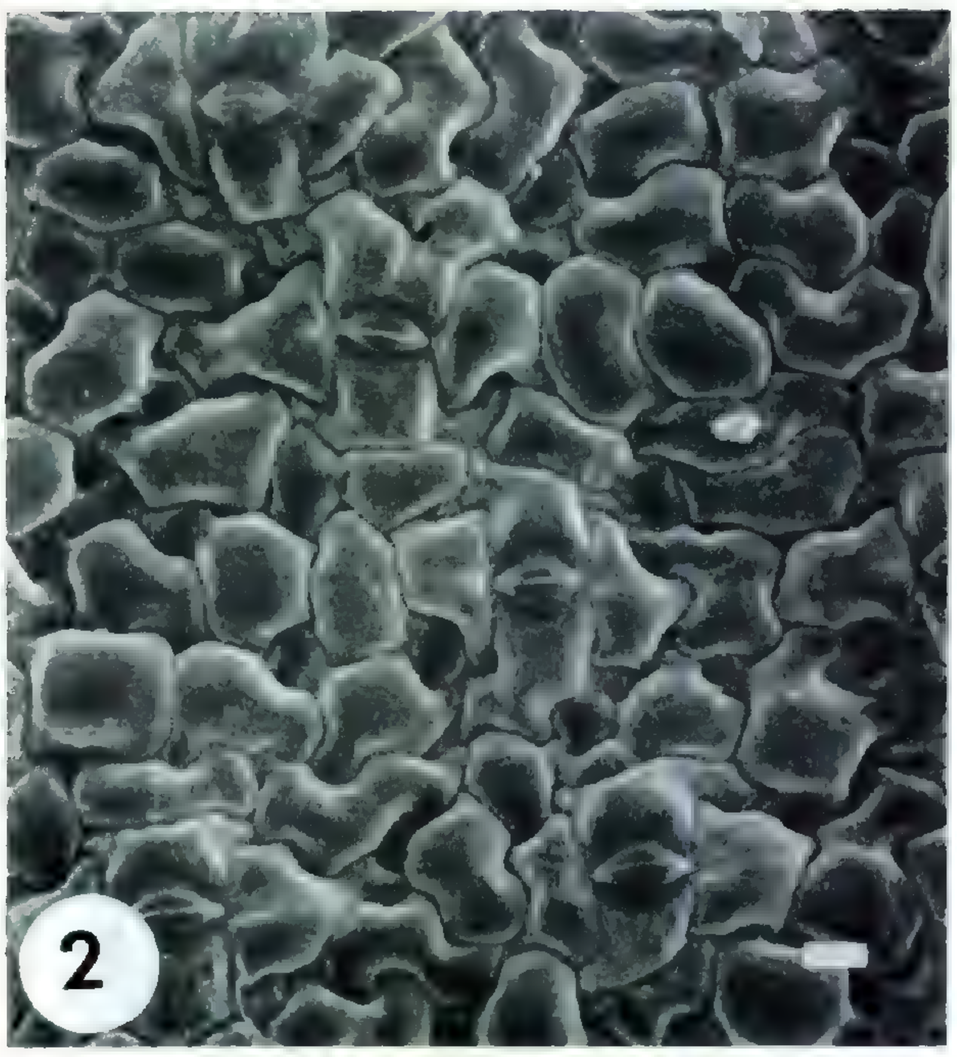
STOMATA

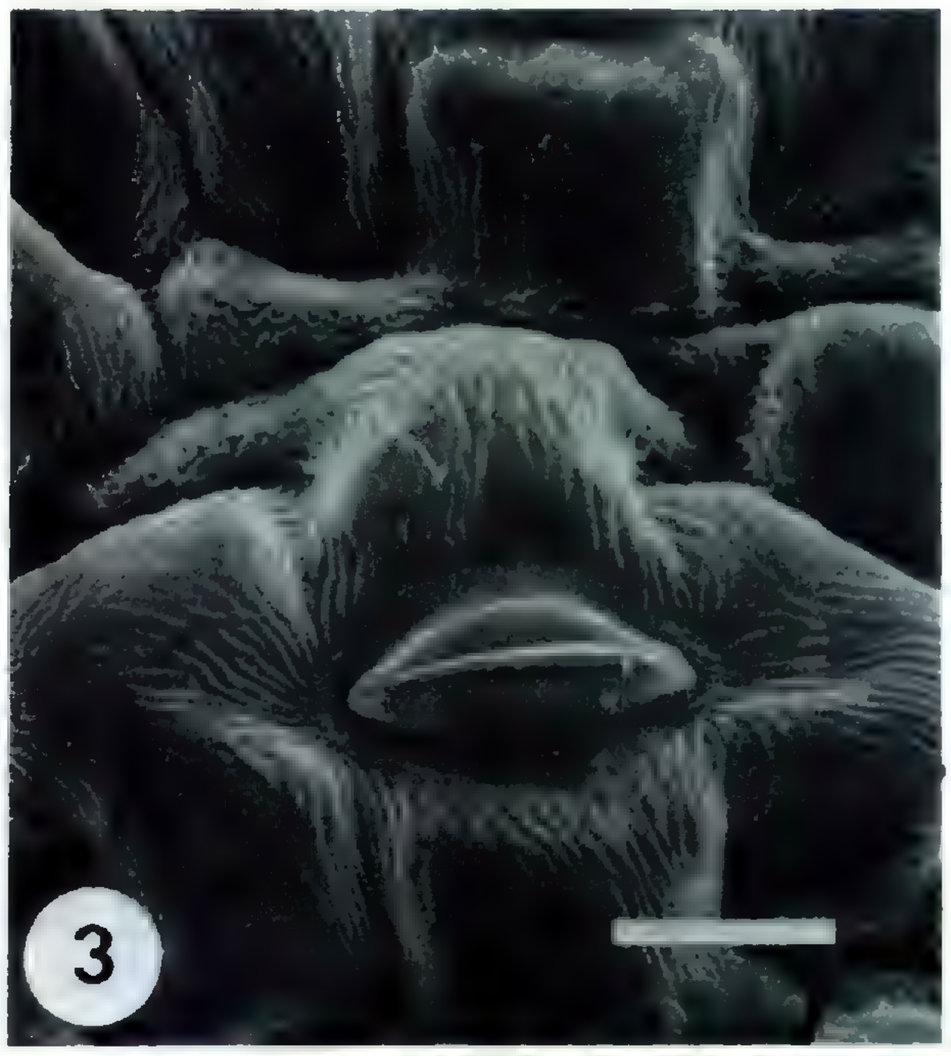
Leaves of *Eucharis* and *Caliphruria* are predominantly hypostomatic. Stomata occur adaxially only along the midrib and vicinity (Fig. 14A), and occasionally in the proximity of primary veins. Stomata are usually absent from the abaxial midrib (Fig. 14B). Intercalary stomata were regularly observed only in *E. cyaneosperma* Meerow (Figs. 7, 15D). The stomata of *Eucharis* and *Caliphruria* are anomocytic, as is typical for Amaryllidaceae (Arroyo & Cutler, 1984; Dahlgren & Clifford, 1982), though *E. astrophiala* exhibits at least slight differentiation of cells neighboring the stomata (Figs. 2, 3) from other epidermal cells. These cells are more densely and regularly striate than other epidermal cells, as well as slightly more raised. The guard cells of *Eucharis* and *Caliphruria* are oriented with their longest axis parallel to that of the leaf.

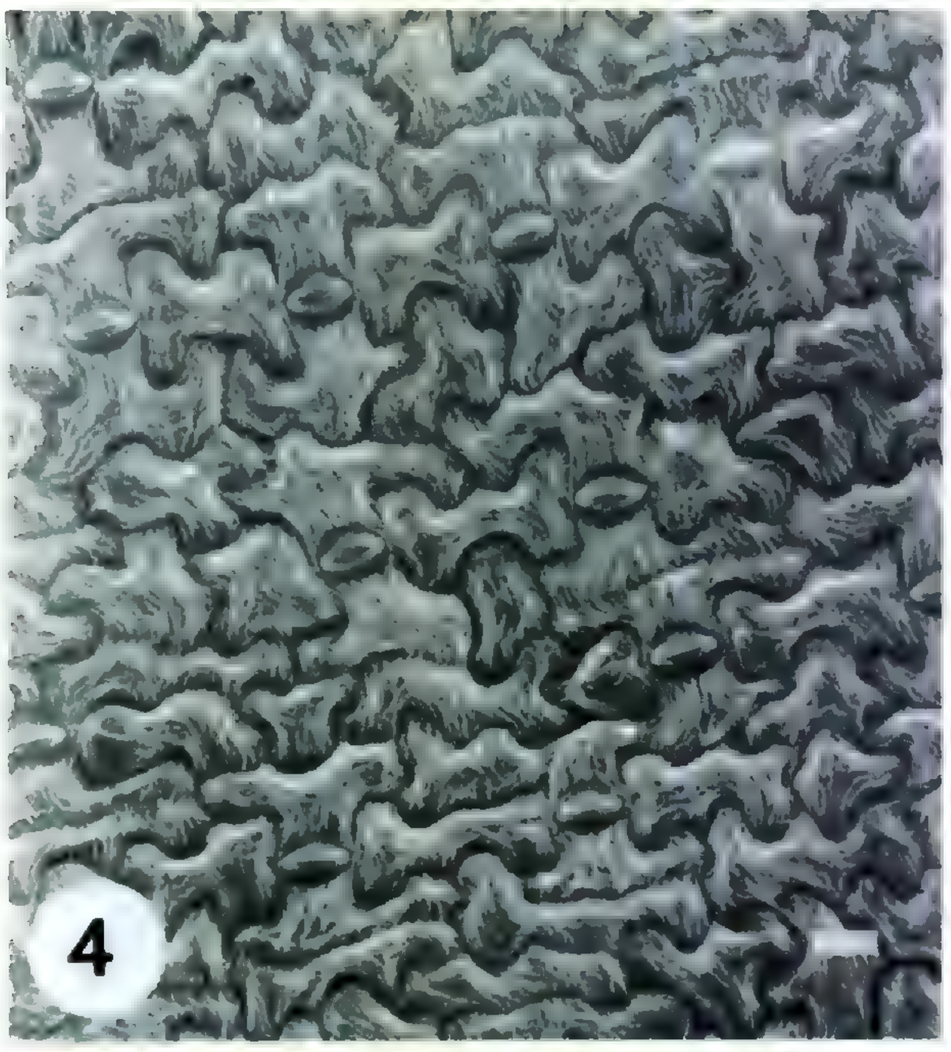
EPIDERMAL CELLS

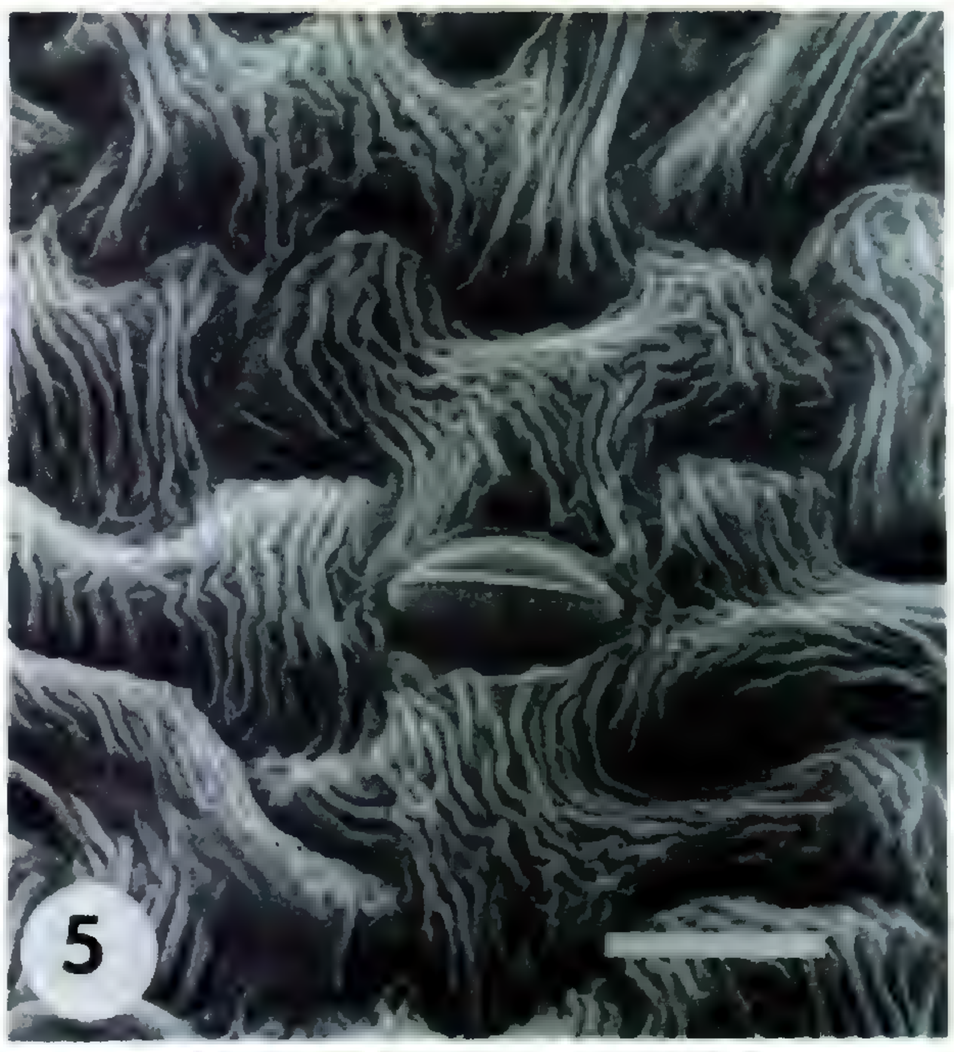
Abaxial epidermal cells range from rectangular to irregular in shape. Adaxial epidermal cells are in almost all cases rectangular. *Eucharis astrophiala* (Fig. 15A) has the most irregularly shaped cells of both the abaxial and adaxial surfaces. In the vicinity of the midrib on both surfaces of the leaf (Fig. 14), epidermal cells become conspicuously elongated, and anticlinal walls are straight. Epidermal cells of the midrib are extremely long and narrow.

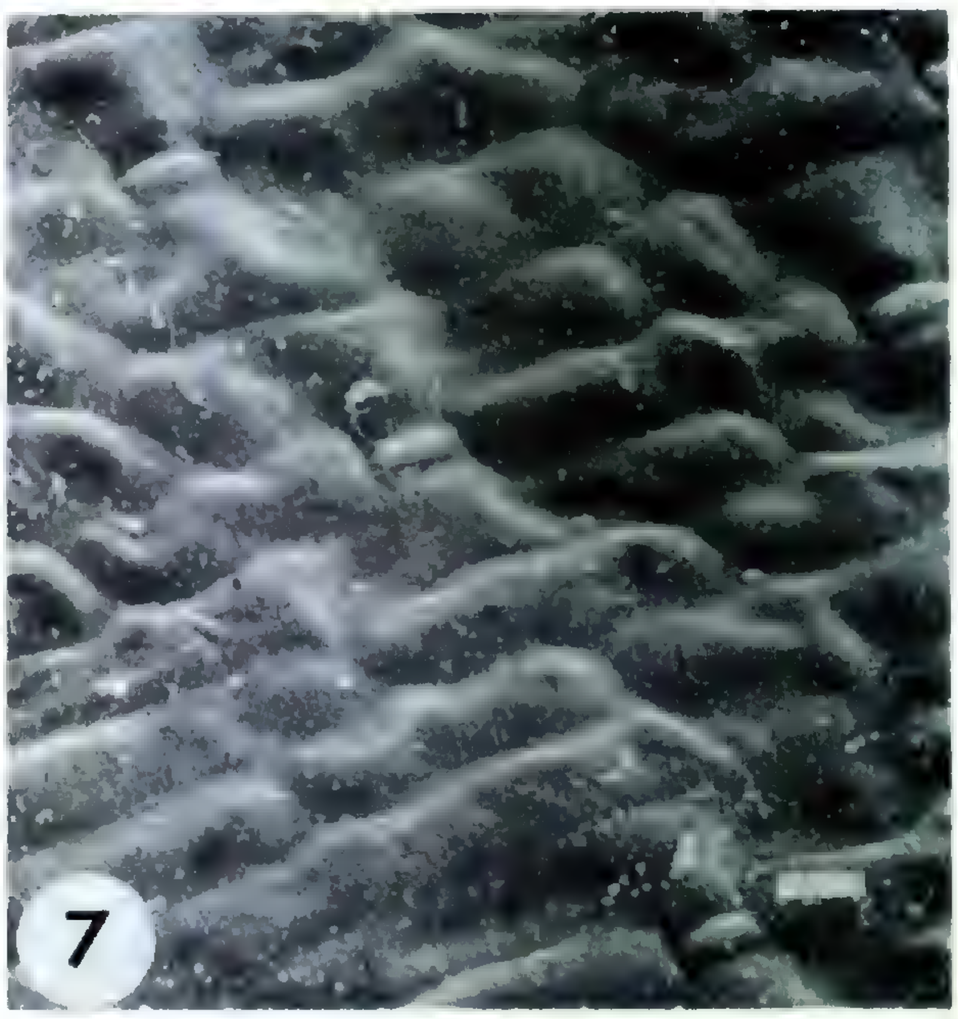
The epidermal cells of all species of *Eucharis* subg. *Eucharis* have strongly undulate anticlinal walls (Fig. 15), as noted by Asatrian (1984) for the few species he surveyed. End walls of both the abaxial and adaxial cells of all species range from oblique to rounded. Abaxial cells are more strongly











FIGURES 2–7. SEM photomicrographs of *Eucharis* leaf surfaces. 2–6. undulate than those of the adaxial surface. Epidermal cells of *Caliphruria* (Fig. 15F) are more weakly undulate than those of *Eucharis*. The anticlinal walls of adaxial cells of *C. korsakoffii* are completely straight. *Eucharis* subg. *Heterocharis* is polymorphic for anticlinal wall morphology. *Eucharis amazonica* and *E. sanderi* have strongly undulate walls, while *E. moorei* (Fig. 15E) has essentially straight walls.

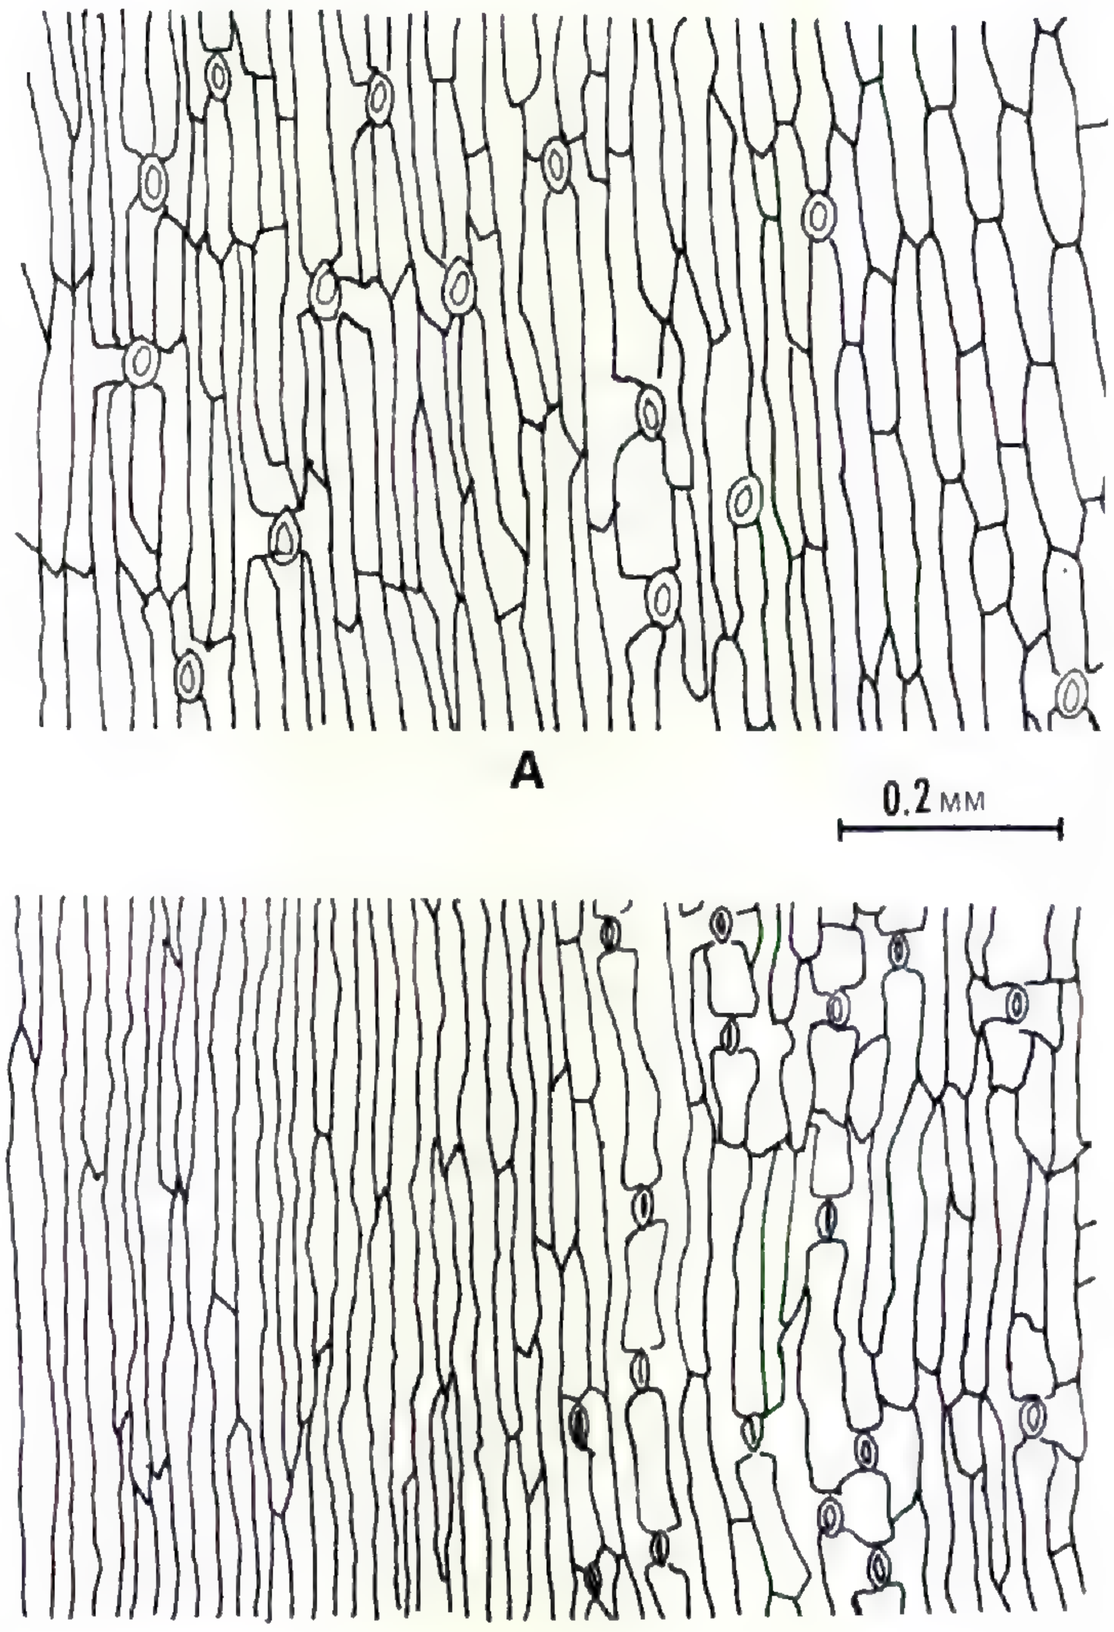

FIGURE 14. Leaf epidermal cell configurations in the vicinity of the midrib of representative *Eucharis* species.—A. *E. formosa* (*Schunke 14174*, FLAS), adaxial surface.—B. *E. plicata* subsp. *plicata* (*Meerow et al. 1025*, FLAS), abaxial surface.

LEAF ANATOMY

In petiolar transverse section, a single arc of vascular bundles is usually observed (Fig. 1). Median bundles are the largest. In petioles of *E. moorei* (Fig. 1E) and the closely related *E. amazonica* (Fig. 1F), both in subg. *Heterocharis*, small secondary bundles were observed near the adaxial surface. These bundles are most conspicuous in *E. moorei*; they are markedly smaller in *E. amazonica*. These secondary vascular traces disappear above the middle of the petiole. Asatrian (1984), who reported on petiole anatomy of three *Eucharis* and *Caliphruria* species, did not observe these bundles in *E. amazonica* (cited as *E. grandiflora*).

The internal morphology of leaves of *Eucharis* and *Caliphruria* (Figs. 16–22) is largely invariant across both genera. No well-defined palisade layer is evident, the absence of which is characteristic of most genera of "infrafamily" Pancratioidinae (Arroyo & Cutler, 1984). Mucilage cells, common throughout the family (Arroyo & Cutler, 1984), are often present near the leaf surface, and raphides are occasionally observed in epidermal cells. The mesophyll consists of several layers of chlorenchyma both ad- and abaxially, and a thicker region of spongy, slightly aerenchymous tissue. Small air cavities occur regularly only directly below stomata. Vascular bundles are surrounded by a sheath of one or two layer(s) of parenchymous cells. The only xylem elements present are tracheids with annular thickenings (Fig. 19).

FLORAL MORPHOLOGY

INFLORESCENCE

The inflorescence of *Eucharis* and *Caliphruria* is a naked scape typical of Amaryllidaceae. The scape is subterete in cross section and has a solid pith. Vascular bundles are distributed in several irregular, concentric rings within the pith. A layer of collenchyma cells occurs just below the epidermis.

The scape is terminated by two valvate-imbricate, ovate-lanceolate bracts that enclose several secondary bracts and the flower buds before anthesis. These bracts vary from green (*E.* subg. *Heterocharis*) to greenish white (most species of subg. *Eucharis*) and are soon marcescent after opening and spreading laterally. Each flower is subtended by a linear-lanceolate bracteole.

The inflorescence of the Amaryllidaceae is traditionally described as "umbellate." Mann (1959) and Stout (1944) demonstrated that the superficially simple umbel of Amaryllidaceae actually represents a complex series of reduced, helicoid cymes. Anthesis occurs in a strict sequence within each cyme from the developmentally oldest flower to the youngest. The peripheral cymes flower first; the central cymes flower last.

Flower number varies in *Eucharis* and *Caliphruria* from 2 to 10, rarely as many as 12 (*C. korsakoffii*, rarely in *E. castelnaeana*). Number of flowers is often a taxonomically useful character, though any species characterized by 8–10 flowers is capable of producing a depauperate inflorescence with fewer florets. An increase in flower number

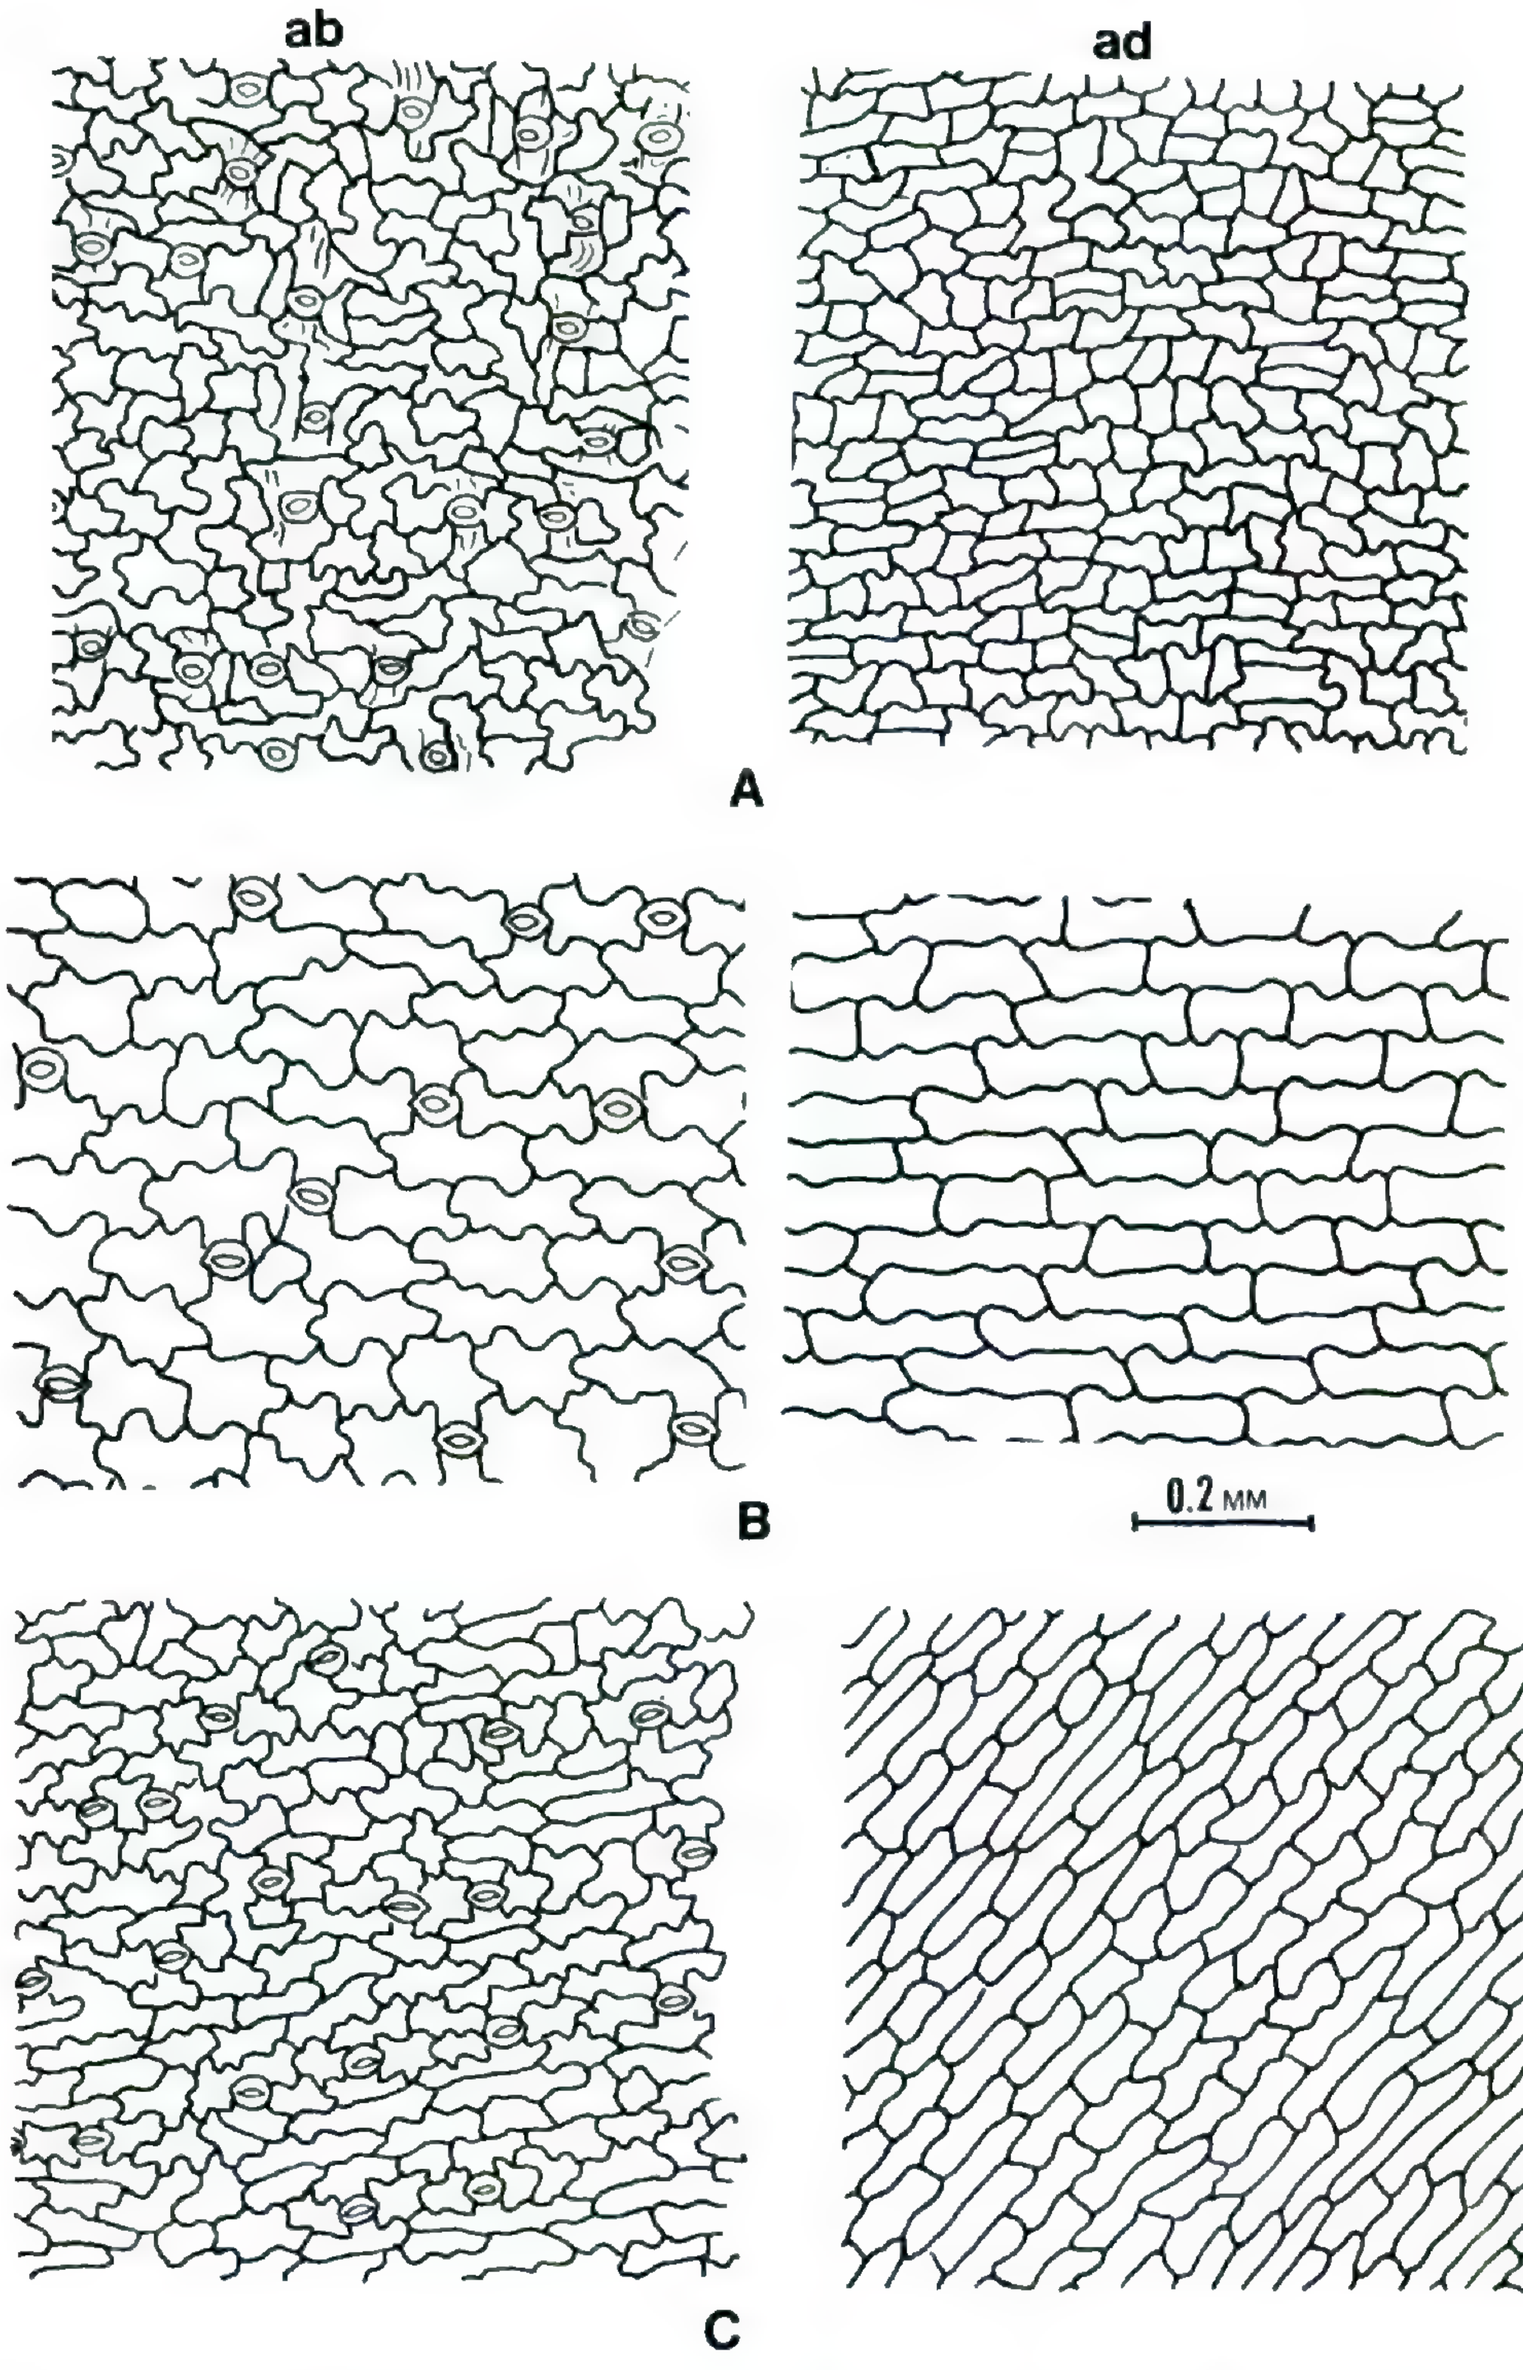

FIGURE 15A–C. Leaf epidermal configurations of representative *Eucharis* and *Caliphruria* species in the intercostal area of the leaf.—A. *E. astrophiala* (*Madison 3792*, SEL).—B. *E. bonplandii* (*Bauml 686*, HUNT).—C. *E. castelnaeana* (*Schunke 14156*, FLAS).

generally does not occur. In some species of subg. *Eucharis* (*E. astrophiala*, *E. bouchei*, *E. ulei*), a flower number of five has become virtually fixed. Reduction in flower number is usually considered the derived state in Amaryllidaceae (Traub, 1962, 1963).

FLOWER SIZE

The largest flowers in *Eucharis* are found in subg. *Heterocharis*, where they average 7–8 cm in length. Flowers of *Caliphruria* are the smallest, never exceeding 4 cm long. Subgenus *Eucharis*, the largest of the two subgenera of *Eucharis*, is variable, with flowers 3–7 cm in length. Within a fairly broad range, flower size can be used to distinguish phenetic species complexes within subg. *Eucharis*; however, most species of this subgenus are quite variable in size (Meerow, 1987d, in press).

FLORAL FRAGRANCE

Subgenus *Heterocharis* is the only subgenus of *Eucharis* with uniformly fragrant flowers. The fragrance of all species of subg. *Heterocharis* is intense and sweet. Flowers of *Caliphruria* do not emit any detectable fragrance. Most species of *Eucharis* subg. *Eucharis* also lack noticeable fra-

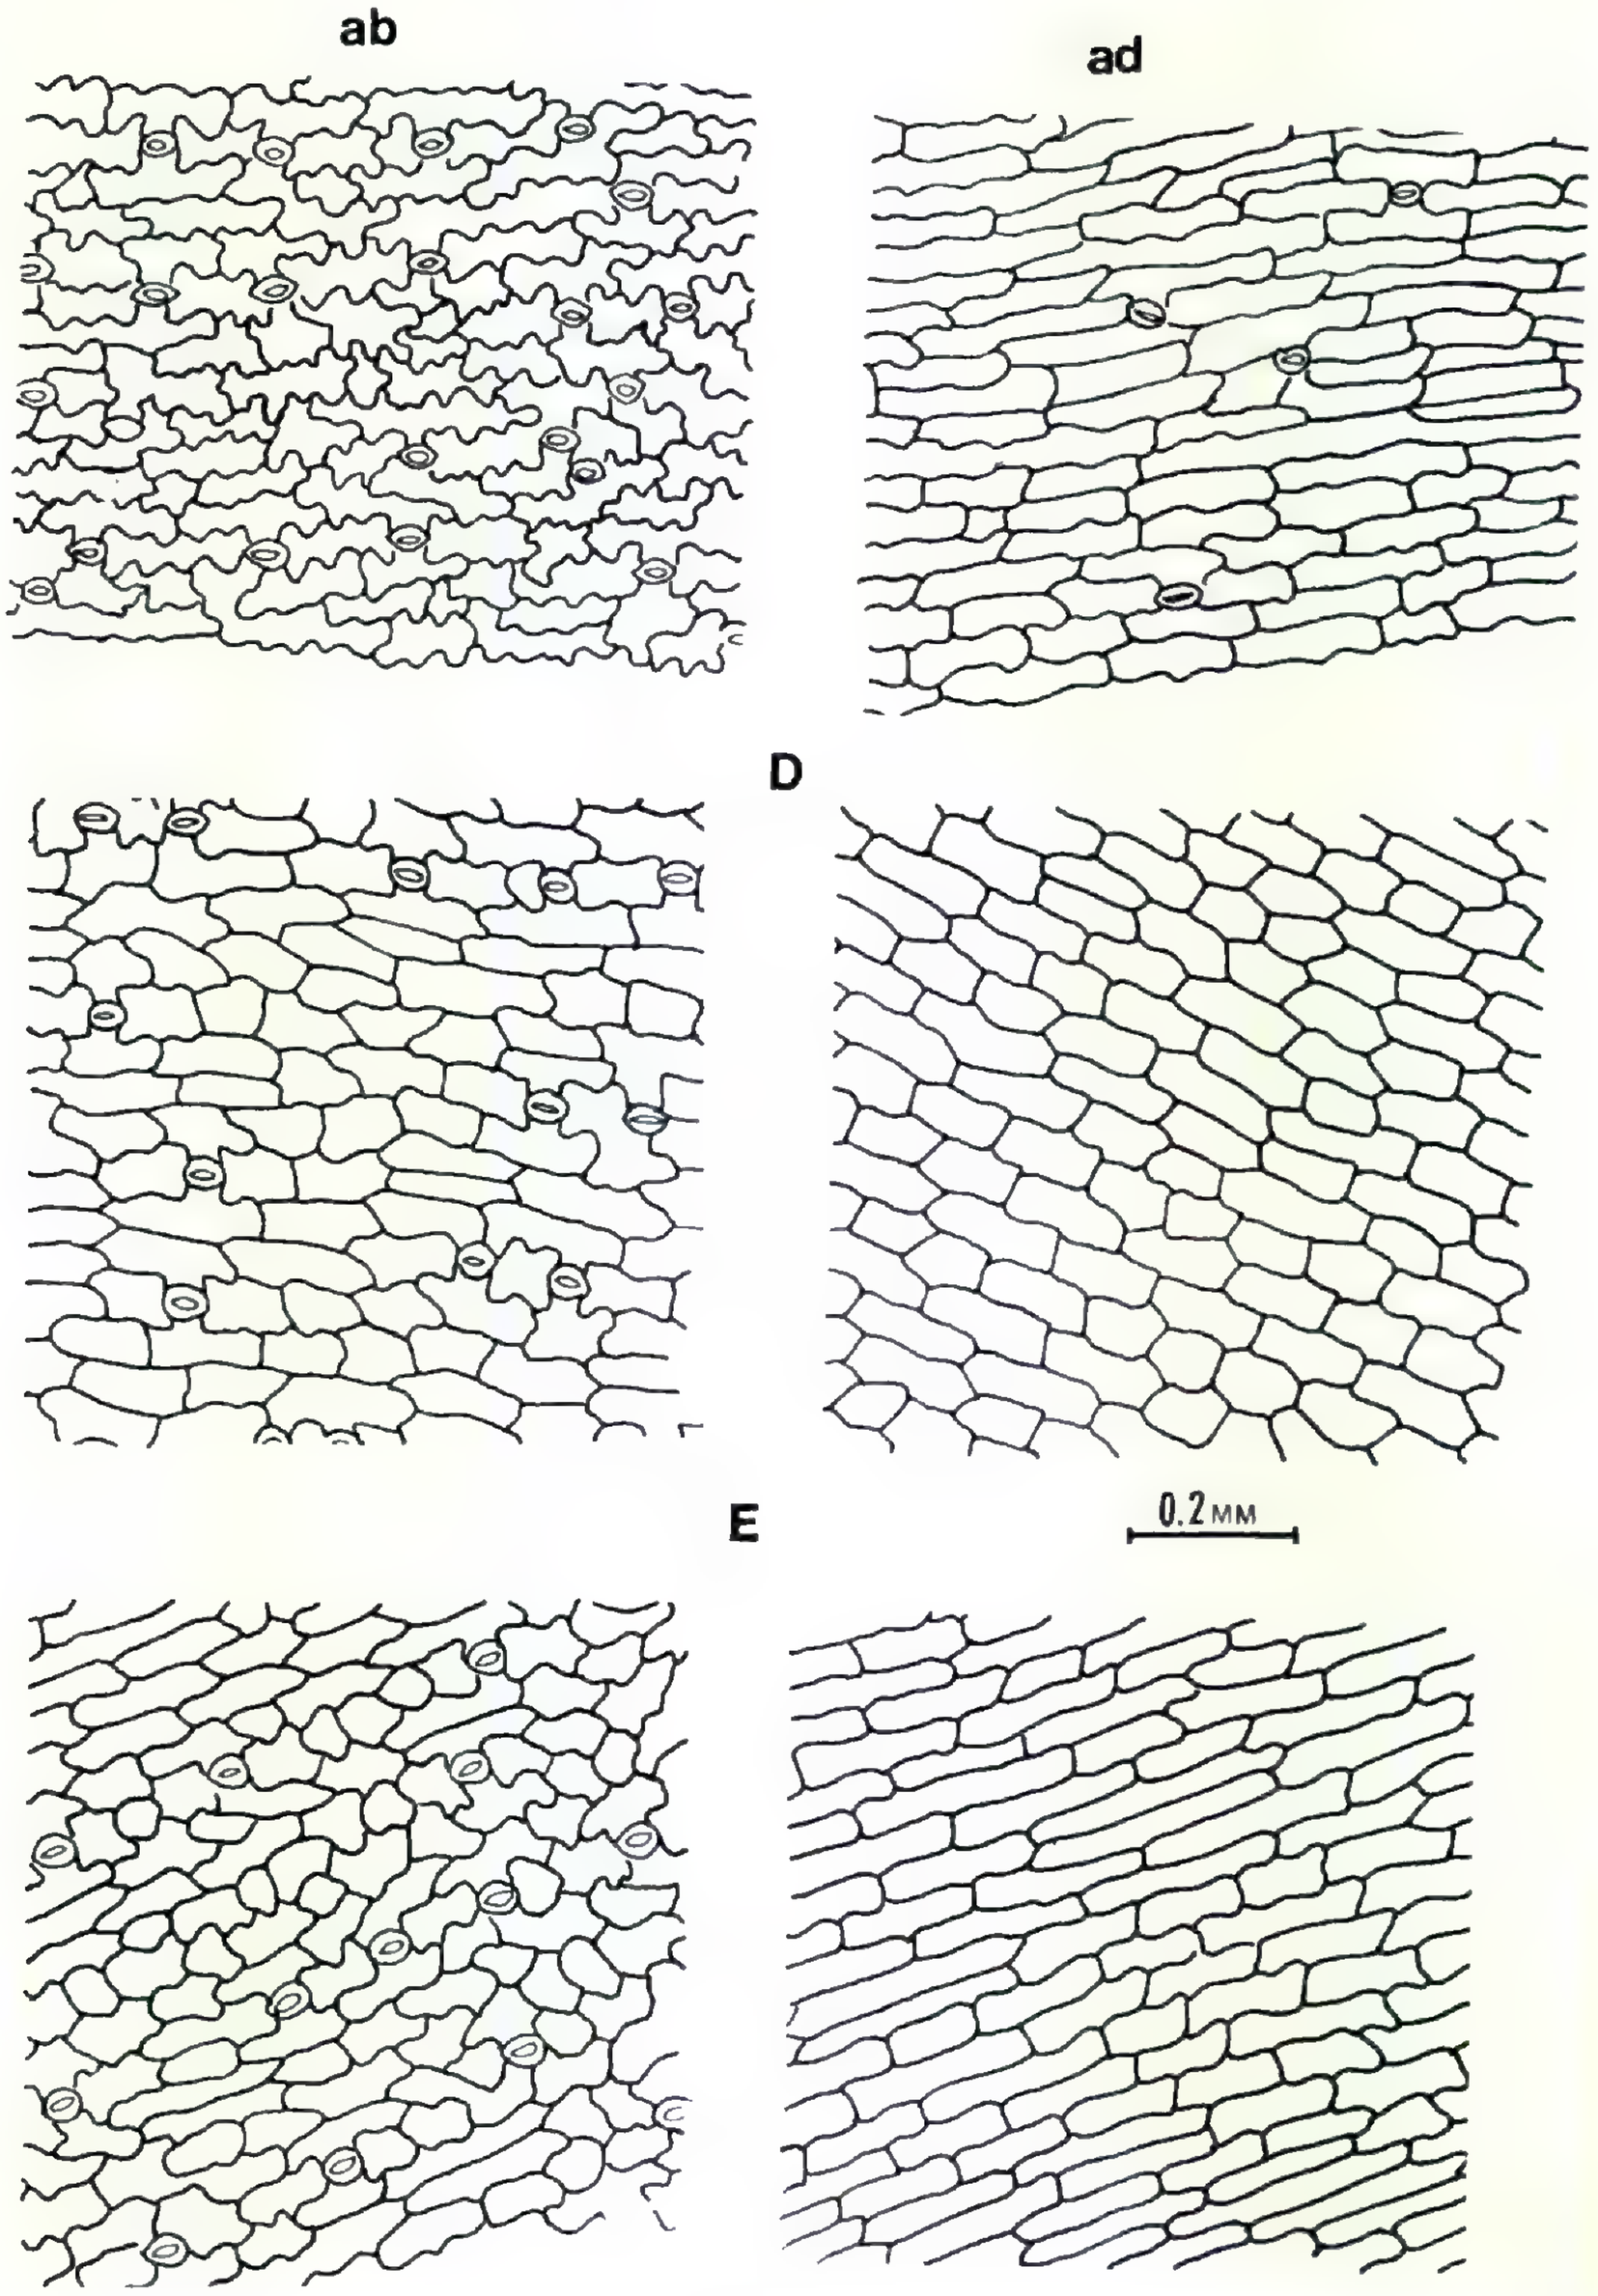

FIGURE 15D–F. Leaf epidermal configurations of representative *Eucharis* and *Caliphruria* species in the intercostal area of the leaf.—D. *E. cyaneosperma* (*Meerow 1032*, FLAS).—E. *E. moorei* (*Meerow 1141*).—F. *C. subedentata* (*Meerow 1123*, FLAS). ab = abaxial, ad = adaxial.

grance. In the few fragrant species of this subgenus (*E. bakeriana* N. E. Brown, *E. castelnaeana* (Baillon) Macbr., *E. formosa* Meerow, and *E. plicata* Meerow subsp. *brevidentata* Meerow), the odor is not intense. In *E. formosa* the odor is slightly fetid.

PERIANTH

The perianth of *Eucharis* and *Caliphruria* consists of six tepals in two whorls, basally connate into a tube of varying length and morphology. The tube of *Eucharis* subg. *Eucharis* (Fig. 23E) is cylindrical for almost its entire length, abruptly dilating near the perianth throat. The tube of subg. *Eucharis* is also strongly curved, either abruptly just above the ovary (*E. bakeriana*, *E. cyaneosperma*) or gradually throughout the proximal half of its length (all other species). The curving of the tube results in the pendent habit of most species of subg. *Eucharis*. The tube is white for its entire length.

The tube of subg. *Heterocharis* (Fig. 23C, D) is tinted green proximally (for as much as half its length). The tube is curved, though not as markedly

FIGURES 16–22. as that of subg. *Eucharis*, and the habit of the flowers is either declinate (*E. moorei*, *E. sanderi* Baker) or subpendulous (*E. amazonica*). The tube is cylindrical for ½ to ⅔ of its length; it abruptly dilates in the distal ½ to ⅓. The tube morphology of ×*Calicharis butcheri* (Traub) Meerow (Fig. 23B), putatively an intergeneric hybrid between *E. sanderi* and *C. subedentata*, is intermediate be-

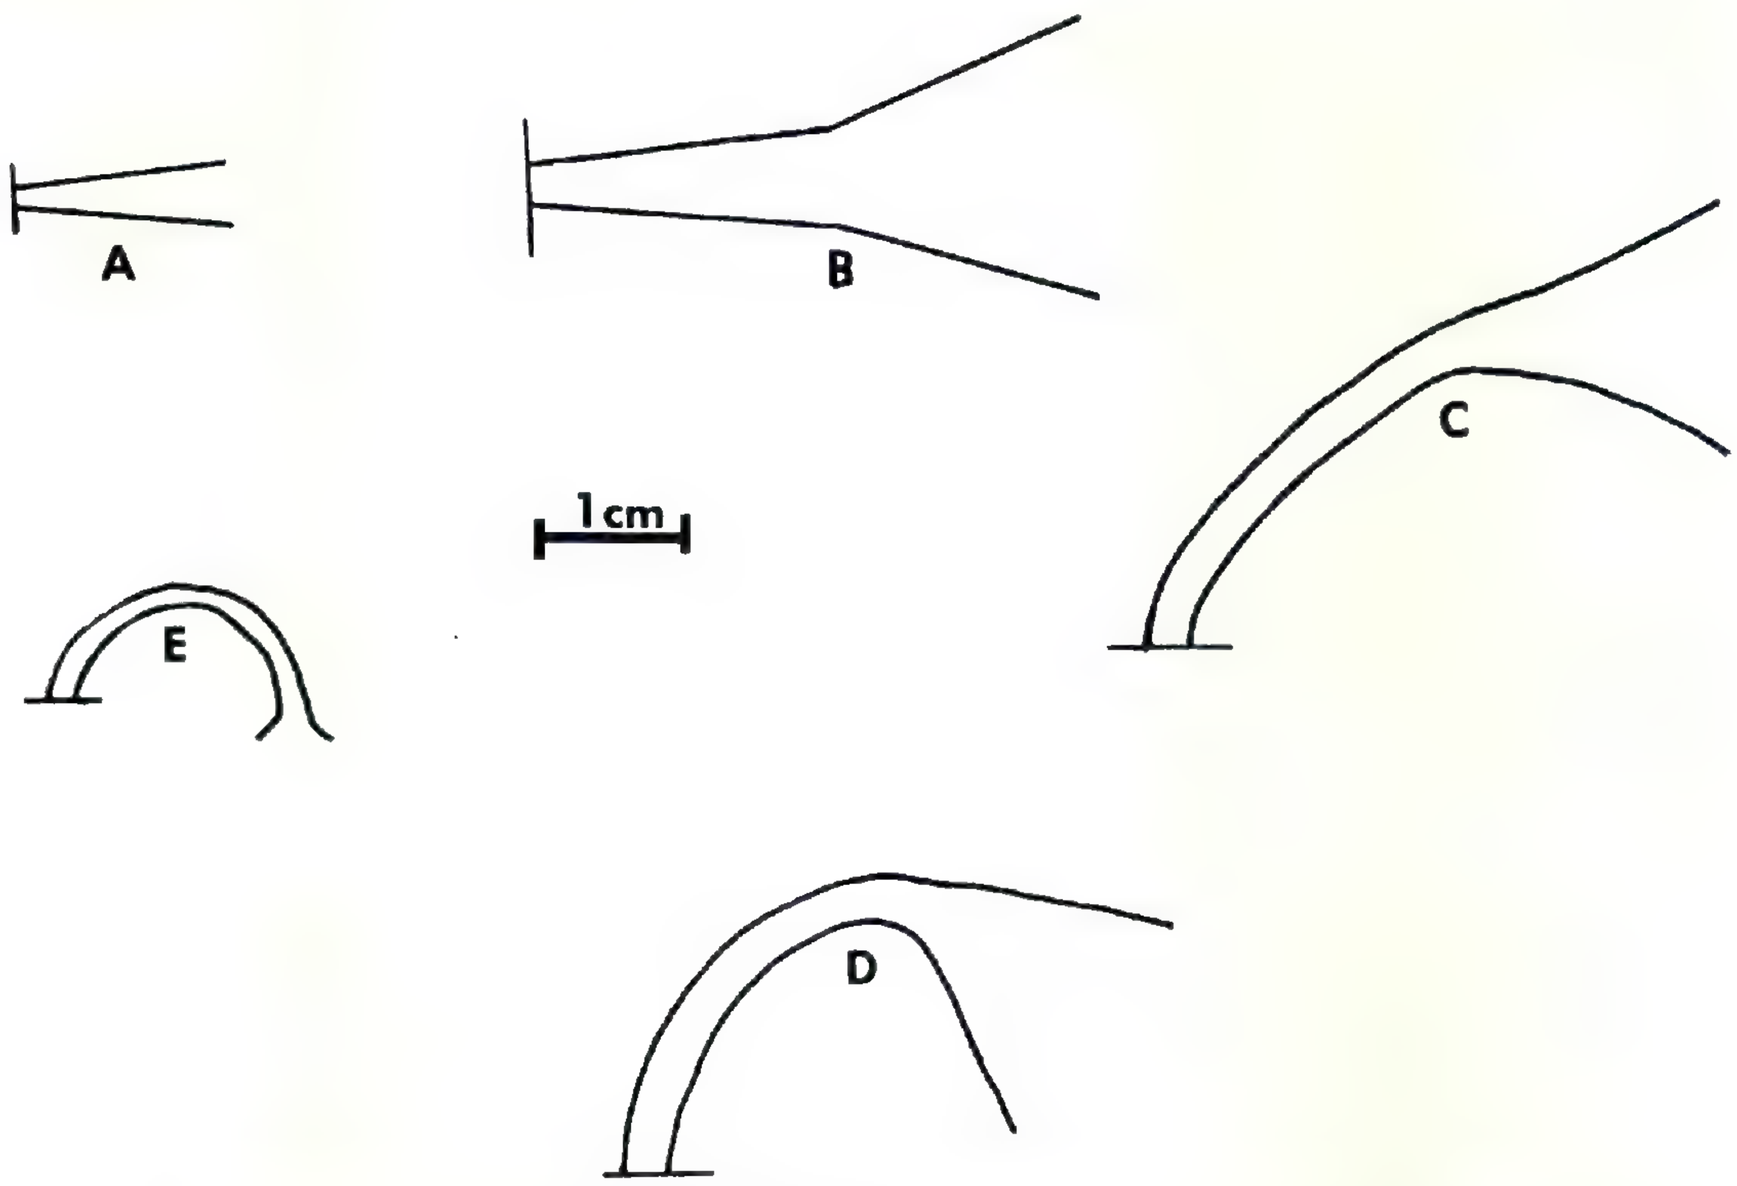

FIGURE 23. Perianth tube morphology of *Eucharis* and *Caliphruria* species or hybrids.—A. *C. subedentata* (*Meerow 1098*, FLAS).—B. ×*Calicharis butcheri* (*Meerow 1110*, FLAS).—C. *E. sanderi* (*Cuatrecasas 16380*, F).—D. *E. amazonica* (*Schunke 14179*, FLAS).—E. *E. astrophiala* (*Madison 3792*, SEL).

tween *Caliphruria* (Fig. 23A) and *Eucharis* subg. *Heterocharis* (Fig. 23C, D).

The tube of *Caliphruria* (Fig. 23A) is straight and dilates gradually from base to throat. It is either subcylindrical (*C. korsakoffii*) or funnelform (all other species). The tube is tinted green proximally (in *C. subedentata*, for ½–⅔ of its length).

The tepals of *Eucharis* and *Caliphruria* flowers are white. Those of the outer series are almost always longer and narrower than the inner tepals. The outer tepals are apiculate. The apiculum frequently has a small, papillate horn on the adaxial surface in *Eucharis* subg. *Eucharis*. The inner tepals vary from acute to obtuse, sometimes minutely apiculate, at the apex.

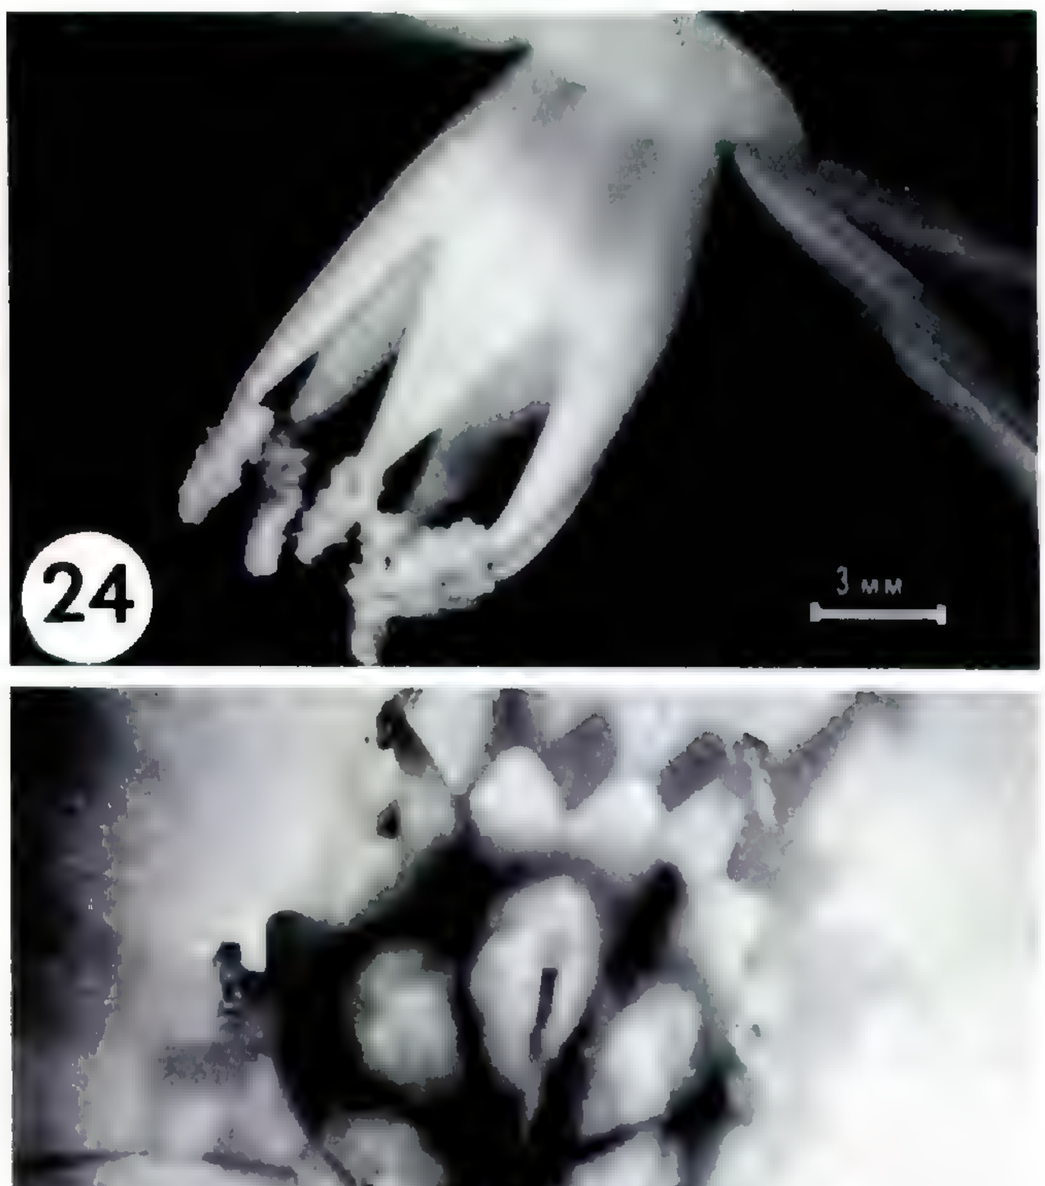
The tepals of most species of subg. *Eucharis* spread at an angle of 90° or more from the throat. Perianth morphology of subg. *Eucharis* is thus predominantly crateriform. At times the tepals may be reflexed strongly above the midpoint of their length, or rarely for their entire length. Tepal habit varies even among flowers of the same inflorescence and shows no taxonomic consistency. If exposed to strong light, the abaxial midrib of the tepals of some species of subg. *Eucharis* may be lightly pigmented yellow.

The perianth of *Caliphruria* is infundibular. The tepals remain imbricate for half their length and spread distally at angles of only 45–60°. The tepals of subg. *Heterocharis* are also for the most part imbricate proximally and spread at 45–60° from the throat. The perianth is more or less campanulate. One species, *E. amazonica*, has the crateriform perianth characteristic of subg. *Eucharis* with a wide-spreading (ca. 90°) limb.

ANDROECIUM

The stamens of *Eucharis* and *Caliphruria* are variously connate proximally. In all but three species of *Eucharis*, a conspicuous staminal cup is present (Figs. 24, 25). In *Caliphruria*, the cup is reduced to a short, membranous, connate portion of the filaments near the perianth throat (Fig. 26). *Eucharis sanderi* (subg. *Heterocharis*) has a reduced staminal cup similar to that of *Caliphruria*. Staminal connation is one of the major characteristics of "infrafamily" Pancratioidinae. Some taxonomic workers considered the staminal cup of pancratioid genera homologous to the corona of *Narcissus* L. (e.g., Pax, 1888). The corona of *Narcissus* is generally considered to be of perianthal origin (Eichler, 1875; Arber, 1937), while the staminal cup of pancratioid taxa has been described as composed entirely of androecial tissue (Arber, 1937; Singh, 1972). Einsiedel (1987) and Müller-Doblies (pers. comm.) consider this distinction artificial and claim that both structures arise from the same meristematic potential, citing putative instances of polymorphy for both types within the same genus.

Stamens of *Eucharis* and *Caliphruria* may be dentate, edentate, or irregularly toothed. Both types of staminal morphology may occur in the same species, and variation may occur even among flow-



FIGURES 24–26. Androecial morphology of *Eucharis* and *Caliphruria* species.—24. *E. astrophiala* (*Madison 3792*, SEL).—25. *E. amazonica* (*Schunke 14179*, FLAS).—26. *C. subedentata* (*Meerow 1109*, FLAS).

ers of a single clone (Meerow, 1986). The presence or absence of staminal dentation has frequently been overweighted in the alpha-taxonomic literature relating to these genera (e.g., Ravenna, 1982) but can still be of taxonomic significance (e.g., *E. astrophiala* (Fig. 24), the only species of subg. *Eucharis* that always has an edentate staminal cup).

A variable pattern of green or yellow pigmentation is present in the androecium of all species of subg. *Eucharis* and *Heterocharis*. Stamens of *Caliphruria* are completely white. In subg. *Heterocharis*, the green (rarely yellowish) pigmentation is largely restricted to the interior of the cup, and extends into the dilated portion of the tube as well (Fig. 25). The coloration is concentrated along the filamental traces, but the tissue between the traces is also suffused with green. In subg. *Eucharis*, pigmentation is present on both the exterior and interior surfaces of the cup, does not extend into the dilated portion of the tube, and takes the form of either broad spots below each free filament or a uniform band of color at the basal ½–⅓ of the cup. In this subgenus, the pattern is of limited taxonomic significance. Whether the pigmentation functions as nectar guides for pollinating animals is unknown.

The stamens of most species of subg. *Eucharis* constrict distally into a broadly subulate portion (greater than 1 mm wide for most of its length) of varying length. Only in *E. astrophiala* (Fig. 24) and *E. bouchei* (in part) do the stamens constrict gradually from the rim of the staminal cup to the apex of the filament. The free filaments of *Caliphruria* are narrowly subulate (less than 1 mm wide for most of their length, Fig. 26). The free filaments of *E. sanderi* (subg. *Heterocharis*) are narrowly subulate and slightly incurved. Those of *E. moorei* and *E. amazonica* are broadly subulate.

Anthers of *Eucharis* are introrse, dehiscing longitudinally, and either dorsifixed or sub-basifixed. They are most frequently oblong but are linear in subg. *Heterocharis*. At anthesis, the anthers of *Caliphruria* and *Eucharis* subg. *Eucharis* are erect but become versatile as they age. In subg. *Heterocharis*, the anthers are versatile at anthesis.

STIGMA AND STYLE

Of the sixteen species of *Eucharis* and *Caliphruria* observed in cultivation, all but *E. castelnaeana* are protandrous. Stigma receptivity does not occur until the second or third day following anther dehiscence. In some cases, the stigma does not fully expand until the perianth has begun to senesce. Successful greenhouse pollinations have been accomplished after the onset of perianth senescence. In the single known autogamous species, *E. castelnaeana*, stigma receptivity and anther dehiscence coincide.

The styles of *Eucharis* and *Caliphruria* are usually exserted beyond the anthers, most fre-

→

quently 0.5–1 cm. In subg. *Heterocharis*, the styles are somewhat assurgent away from the stamens and are exserted well over 1 cm past the anthers. In two species of subg. *Eucharis*, *E. castelnaeana* and *E. plicata*, the style is included within the cup. In the former species, self-pollination occurs regularly, and stigma receptivity coincides with anthesis.

Stigmas of *Eucharis* and *Caliphruria* (Figs. 27, 29, 30, 32, 33) are obtusely trilobed. Trilobed stigmas are relatively rare in the Pancratioidinae, and *Urceolina*—sister group to *Eucharis* and *Caliphruria*—has a capitate, entire stigma. Traub (1963) and Traub & Moldenke (1949) considered a trilobed or trifid stigma the ancestral state in the Amaryllidaceae.

The stigmatic papillae of *Eucharis* are unicellular (Figs. 28, 34–37), while those of *Caliphruria* (Fig. 31) are multicellular, consisting of both a stalk cell and globose head cell. ×*Calicharis butcheri*, putatively a natural hybrid of *E. sanderi* and *C. subedentata*, has the multicellular stigmatic papillae (Figs. 38, 39) characteristic of *Caliphruria*. Heslop-Harrison & Shivanna (1977) characterized the stigmas of *Eucharis* and *Caliphruria* as dry-type.

OVARY AND OVULES

The ovary of *Eucharis* and *Caliphruria* is inferior and contains septal nectaries. It is green, with the exception of two species, *E. astrophiala* and *E. castelnaeana* (subg. *Eucharis*), in which the ovary is white at anthesis. Ovaries of *Eucharis* and *Caliphruria* range from oblong-ellipsoid (subg. *Heterocharis*) to globose or subglobose (*Caliphruria* and *Eucharis* subg. *Eucharis*). The ovary of subg. *Heterocharis* appears rostellate after senescence of the perianth.

The ovules of *Eucharis* and *Caliphruria* are globose, anatropous, and borne on axile placentae. Ovule number is quite variable throughout both genera. Within limits, however, this number is characteristic of species or species complexes. Subgenus *Heterocharis* has the largest ovule number in *Eucharis*, generally 16–20 per locule, but occasionally as low as 7 in *E. sanderi* (which otherwise has 16–20 throughout most of its range) and 9–12 in *E. amazonica*. In both *Caliphruria* and *Eucharis* subg. *Eucharis*, ovules do not number more than ten per locule. *Eucharis astrophiala*, *E. bouchei*, *E. bonplandii*, *E. cyaneosperma*, and *E. ulei* characteristically have two ovules per locule, but rarely as many as five.

FRUIT

The mature fruit of *Eucharis* and *Caliphruria* is a triloculicidal capsule typical of the nonbaccate-fruited Amaryllidaceae. In fruit, the pedicel elongates to two or more times its length at anthesis. In *Caliphruria* and *Eucharis* subg. *Heterocharis* (*E. moorei*), the capsule is thin-walled and green, sometimes turning yellow or brown at dehiscence. In subg. *Eucharis*, however, the capsule is leathery and bright orange (Fig. 40), contrasting vividly with the shiny black or blue seeds at dehiscence. It is probable, though unsubstantiated, that the combination of fruit and seed color functions mimetically to attract avian dispersal agents (sensu van der Pijl, 1982). In the single known exception to this characteristic fruit morphology in subg. *Eucharis*, the fruit of *E. castelnaeana* (Fig. 41) remains green until shortly before dehiscence, at which time it yellows and finally turns brown. It is often tardily dehiscent and sometimes abscises before opening, though the seeds within are ripe.

SEED

Regardless of the number of ovules per locule in any species of *Eucharis* and *Caliphruria*, all but a few abort as the fruit matures. Generally one to three seeds are present per locule in mature capsules, but as many as four have been observed (Fig. 40).

The seeds of both *Eucharis* and *Caliphruria* are globose or ellipsoid and turgid, the consequence of copious, oily endosperm and a high moisture content. Left at room temperature, the seeds will shrink away from the testa somewhat as moisture is lost but remain capable of germination. Long-term viability has not been tested.

The seed of subg. *Eucharis* (Fig. 42) is characteristically ellipsoid and has a shiny, smooth black (blue in *E. cyaneosperma*) testa. The single exception so far known is again *E. castelnaeana* (Fig. 43). The seed of this species is wedge-shaped by compression in the capsule, is less turgid than seeds of consubgeneric species, and has a dull, rugose testa. The seed of *E. moorei* (subg. *Heterocharis*) is globose to very slightly compressed and has a brown, slightly rugose testa.

In *Caliphruria*, the seeds of only *C. korsakoffii* and *C. subedentata* are known. Seeds of *C. korsakoffii* are globose, turgid, and have a smooth, lustrous brown testa. Seed of *C. subedentata* is slightly compressed, with a lustrous black but rugose testa.

The testa is alveolate in all species examined (Figs. 44–49). In *E. bouchei* var. *dressleri* Meerow (Fig. 45), abundant wax extrusions are found across the surface. The testa of *Eucharis* and *Caliphruria* seeds is composed of phytomelan (Huber, 1969), a simple, largely inert, carbonaceous compound characteristically present in the seed coat of nonbaccate-fruited Amaryllidaceae (Dahlgren & Clifford, 1982; Huber, 1969). Werker & Fahn (1975) reported the occurrence of phenolic quinones in the phytomelan layer of *Pancratium* seeds. In most species of *Eucharis* and *Caliphruria*, the phytomelan layer is all that remains of the integuments (Figs. 51, 57). In *E. bouchei*, however, there is an additional layer of integument tissue about five cells thick, interposed between the phytomelan and the endosperm (Fig. 55). Whether this may be a consequence of the

tetraploid condition of this species is unknown. Most of the seed body of *Eucharis* and *Caliphruria* is taken up by a copious quantity of endosperm characterized by abundant transfer cells (Fig. 56). At maturity, no remnants of the nucellus were observed.

Most workers (e.g., Baker, 1888; Traub, 1963; Hutchinson, 1959; Dahlgren et al., 1985) have allied *Eucharis* and *Caliphruria* with *Hymenocallis*, *Eurycles*, and *Calostemma* (e.g., tribe Eucharieae, or Eucharideae) on the basis of "fleshy seeds." The last-mentioned three genera do indeed have fleshy, bulbiform, sometimes viviparous seeds, but they are not homologous structures. The "pseudoseed" of *Eurycles* and *Calostemma* is actually an adventitious bulbil (Rendle, 1901). The bulbi-

form propagules of *Hymenocallis*, while true seeds, have thick, fleshy chlorenchymous integuments with a well-developed vascular system and a starch-storing embryo (Rendle, 1901; Whitehead & Brown, 1940). These important seed differences have been overlooked by most phylogenists of the Amaryllidaceae.

The turgid seed of *Eucharis* and *Caliphruria*, despite a high moisture content when first ripe, cannot be accurately described as fleshy. This becomes evident if the seed is allowed to dehydrate slightly at room temperature, and is most apparent in the hard seeds of *E. castelnaeana*, which, at capsule dehiscence, are less turgid than seeds of other species of subg. *Eucharis*. Seeds of *Eucharis* and *Caliphruria* have a reduced integument, represented in most cases only by the compressed phytomelan layer, and have never been observed to germinate viviparously. Phytomelan is absent from the testa of the pseudoseeds of *Eurycles* and *Calostemma*. It is present in only a single species of *Hymenocallis*, *H. quitoensis* Herbert (and probably its close relative *H. heliantha* Ravenna), which has been segregated into the separate genus *Lepidochiton* Sealy (1937) on this basis.

Seeds of *Pancratium* are structurally most similar to those of *Eucharis* and *Caliphruria*. Although variable in shape and surface features (Werker & Fahn, 1975), all species of *Pancratium* have a hard, turgid, ovoid or compressed seed body with copious endosperm (Meerow, unpubl. data; Werker & Fahn, 1975). All examined species of *Pancratium* have a phytomelanous and alveolate testa. Seeds of *Eucharis* and *Caliphruria* have a higher moisture content than those of *Pancratium*, all species of which occur in xeric to seasonally dry habitats.

Pollen Morphology

Pollen morphology of *Eucharis* and *Caliphruria* is reviewed in detail elsewhere (Meerow & Deghan, 1988) and will only be summarized here. Pollen grains of all species of *Eucharis* and *Caliphruria* (Figs. 59–62) are boat-shaped elliptic, monosulcate, heteropolar, and bilaterally symmetrical. The sulcus runs the length of the distal face of the grain. Exine sculpturing is semitectate/reticulate in all species examined.

Pollen of most *Eucharis* falls into Walker & Doyle's (1975) large size class (longest equatorial diameter 50–100 μm). A single species, *E. caucana*, has very large pollen (longest equatorial diameter as much as 110 μm). Pollen of *Eucharis* has average longest equatorial diameters greater than 60 μm, with two exceptions: *E. castelnaeana* and *E. plicata* subsp. *brevidentata*, the two smallest-flowered species. Most species of *Eucharis* have pollen grains with longest equatorial diameters beteen 65 and 75 μm. Pollen of *Caliphruria* falls into the medium size class of Walker & Doyle (1975), with average longest equatorial diameters near 50 μm. Polar diameter of pollen of most *Eucharis* species ranges from 45 to 60.6 μm—diameters less than 40 μm are rare. Polar diameter of pollen of *Caliphruria* is always less than 40 μm. Exine reticulation of *Eucharis* is characteristically coarse (Figs. 59–61), while that of *Caliphruria* is fine (Fig. 62).

Chromosome Cytology

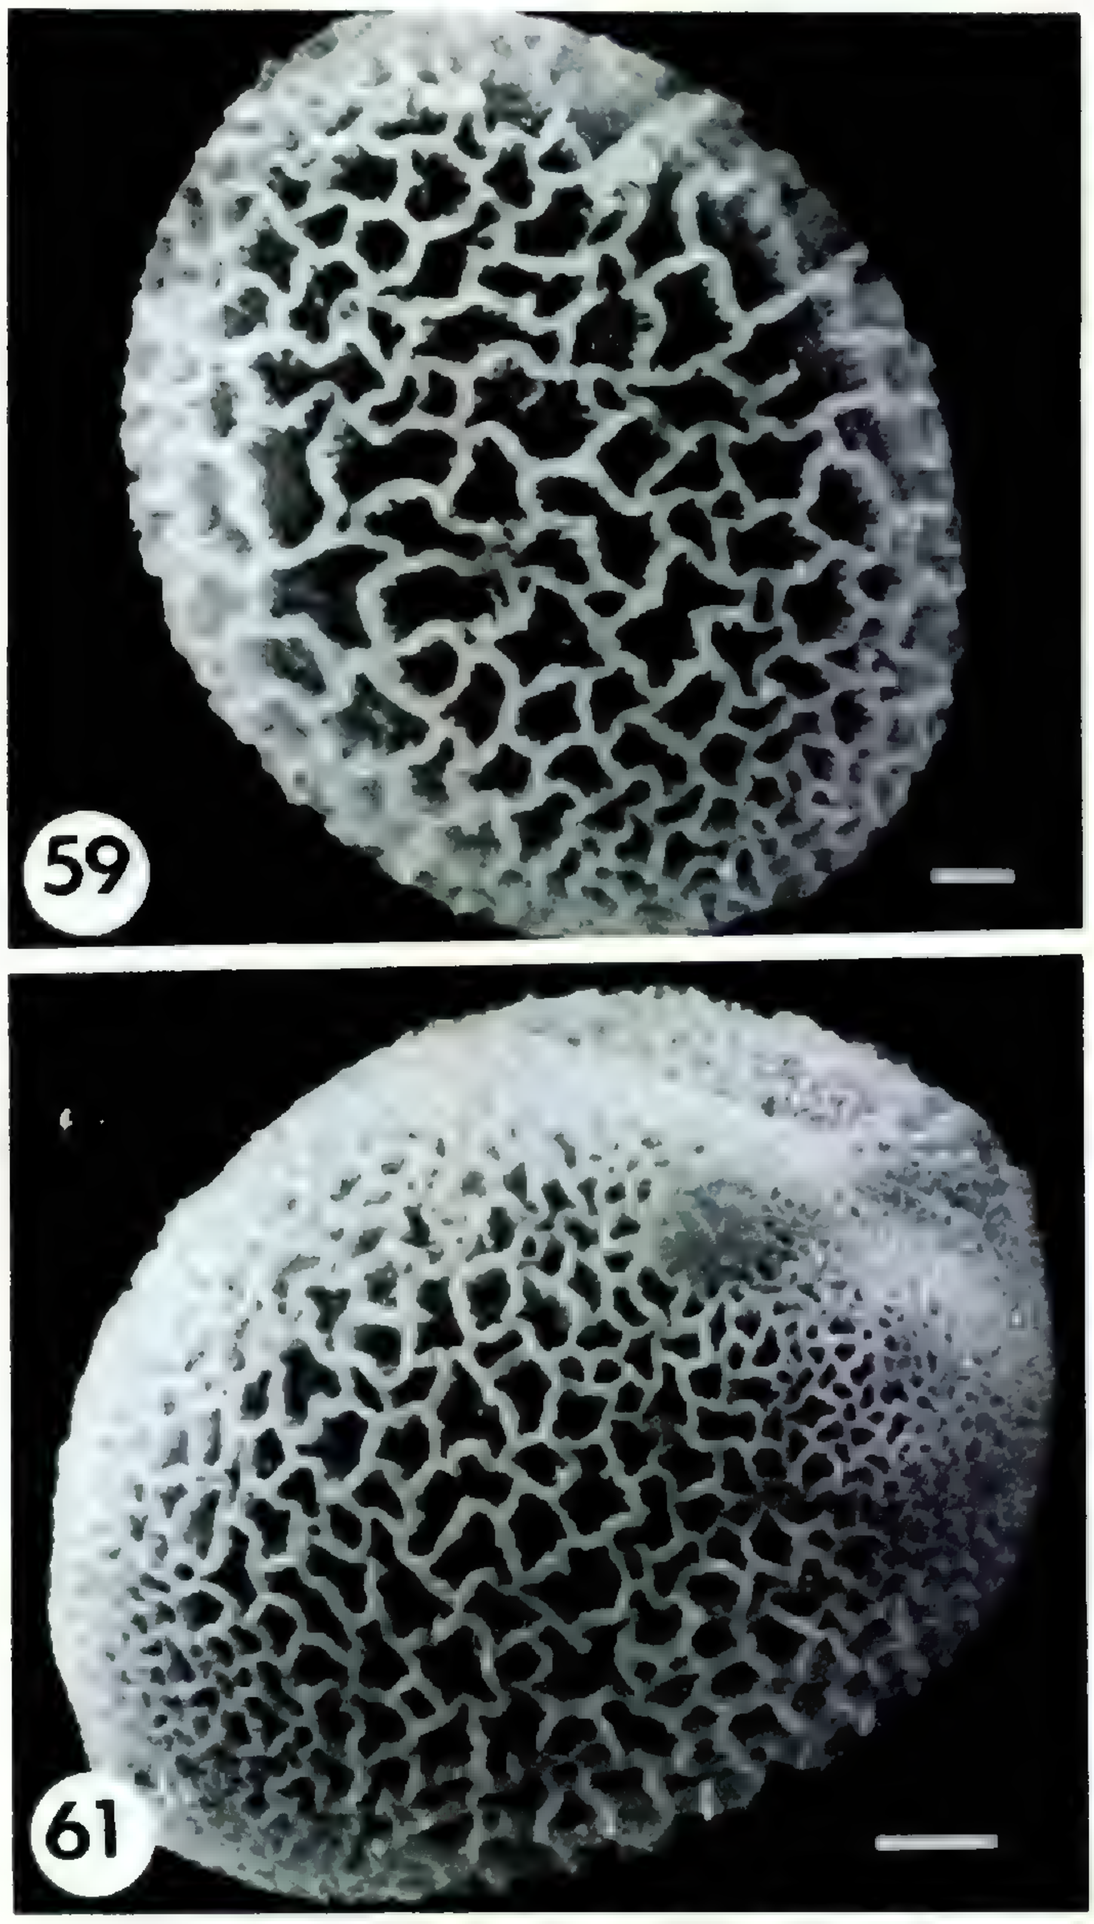
A somatic chromosome number of $2n = 46$ largely characterizes both genera (Meerow, 1987b). Two tetraploid species ($2n = 92$), *E. bonplandii* from Colombia and *E. bouchei* from Central America, are known. *Eucharis caucana*, described in this paper from Colombia, is a hexaploid with the largest chromosome number in the genus ($2n = 138$). *Eucharis amazonica*, $2n = 68$, is the only known departure from these $2x$, $4x$, or $6x$ karyotypes. A somatic chromosome number of $2n = 46$ (or derivations thereof) is characteristic of most genera of neotropical Pancratioidinae (Di Fulvio, 1973; Flory, 1977; Meerow, 1987b, c; Williams, 1981).

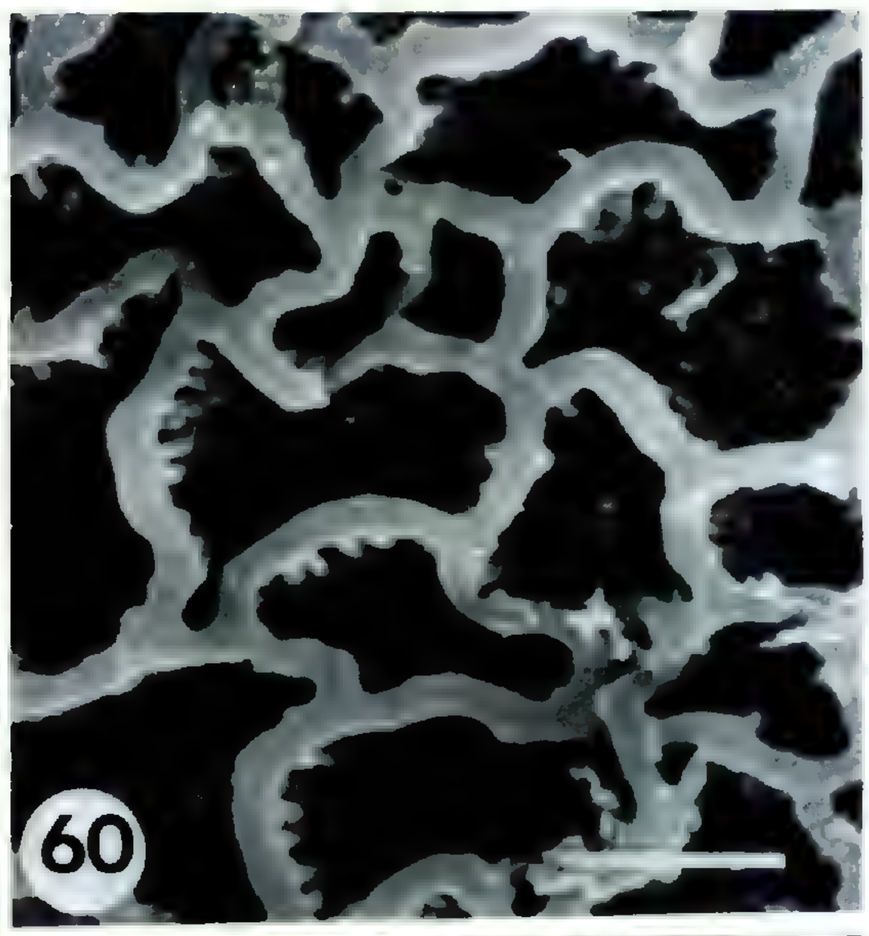
Ecology and Phytogeography

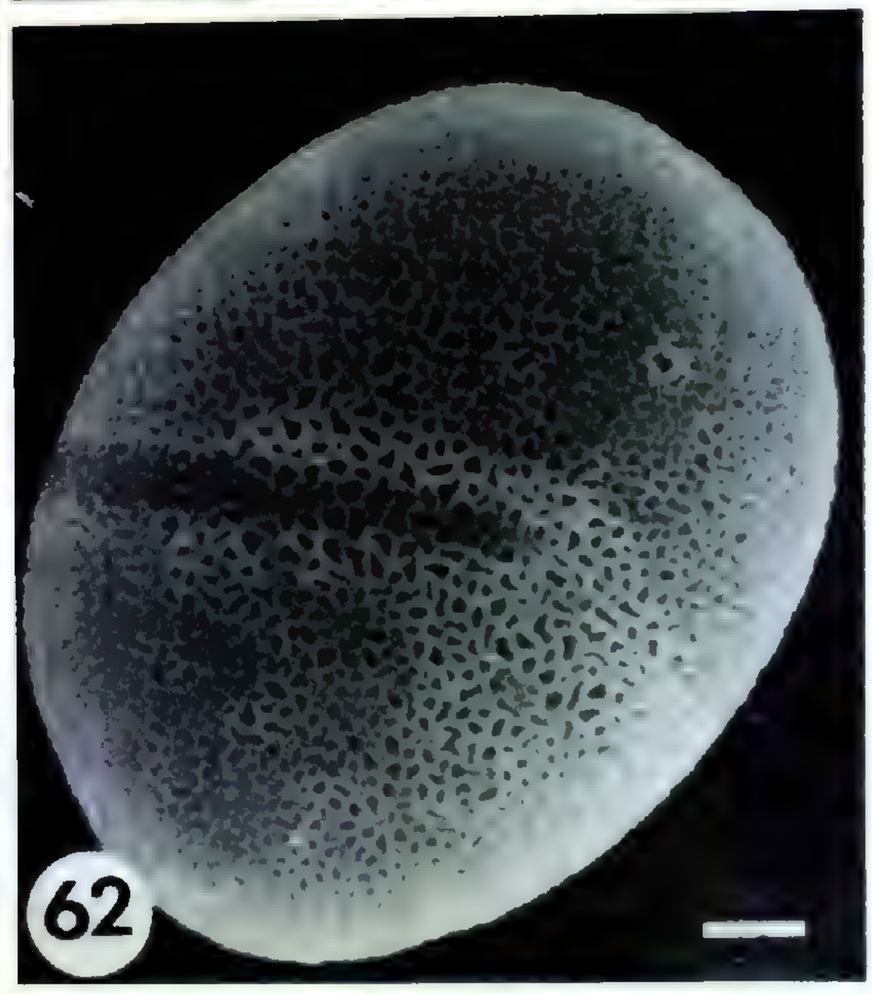
Ecology

All species of *Eucharis* and *Caliphruria* exhibit high fidelity to a primary forest habitat, and severe disturbance of the forest canopy is catastrophic to the plants. In recently cleared forest sites, the bulbs persist for a few seasons, but the leaves developed in sunlight show chlorosis and necrosis. Wilkins (pers. comm.) reported that leaves of *E. amazonica* are damaged at light levels above 5,000 foot candles, an observation confirmed by Rees (1985). Fidelity of these genera to mesic, low-light habitats suggests a strongly evolved adaptive complex. Only two other genera of pancratioid Amaryllidaceae are completely adapted to forest understory: *Eurycles*, a small Australasian genus, and *Urceolina*, sister group to *Eucharis* and *Caliphruria*.

Eucharis populations are often largest on floodplains of small rivers and creeks where frequent short-term inundation is likely. *Eucharis* is also found in more upland sites, but usually in less abundance. No fully deciduous species of subg.







FIGURES 59–62. Representative pollen grains of *Eucharis* and *Caliphruria*. 59, 60. *E. formosa* (*Meerow 1103*, FLAS).—59. Whole grain, proximal polar view.—60. Detail of the exine surface.—61. *E. sanderi* (*Killip 35401*, US), oblique lateral longitudinal view.—62. *C. subedentata* (ex hort. *s.n.*, K), proximal polar view. All scales = ca. 5 μm.

Eucharis have been observed, though *E. astrophiala*, endemic to the western slopes of north-central Ecuador, enters a season of dormancy when growth ceases. Yet several leaves may persist for the duration.

The rarity of *Eucharis* and *Caliphruria* species throughout their range is a striking characteristic of their distribution. Single, widely dispersed clumps of bulbs are more the rule than the exception. Herbarium collections are usually unicates and often indicate the relative infrequency with which the plants were encountered in the forest. The largest population of *Eucharis* that I have observed consisted of about 30 individuals of *E. moorei* in an approximate half-hectare area. Throughout eastern Ecuador, populations of only two or three clonal clumps or single bulbs (and frequently as low as one) of *E. candida*, *E. formosa*, and *E. moorei* are common. In eastern Peru, a careful search through a five-hectare area turned up only two plants of *E. cyaneosperma*. Edaphic conditions are probably important in limiting colonization and establishment of *Eucharis* species. Restriction to sites of high fertility is evident for all species of *Eucharis* and has been noted by floristic workers in the Amazon basin and Chocó region of Colombia (A. Gentry, pers. comm.).

No species of *Eucharis* are found natively above 1,800 m. The overwhelming majority of collections are from elevations below 1,000 m and, of these, more than half are below 500 m. *Caliphruria* is primarily collected at sites above 1,000 m ("selva-subandina" of Cuatrecasas, 1958). Most collections of *Caliphruria* (*C. subedentata*) were from the Río Cauca River valley of western Colombia, an area now largely deforested. In July 1984, I was not able to find members of this genus in any of its historical localities.

PHYTOGEOGRAPHY

More than half of the known species of *Eucharis* subg. *Eucharis* are found on the eastern slopes of the Andes. The majority of these species are concentrated along the Amazon and its main tributaries, e.g., the Napo and Pastaza system in Ecuador and the Huallaga of Peru. Seven of the fourteen extant species of subg. *Eucharis* are endemic to the premontane Andean–Amazonas interface, but no species has been reported east of 68°W longitude. Thus the genus appears to be absent from the great, largely Brazilian expanse of lowland Amazonas. Five peripheral isolate species from the premontane Andean–Amazonian center of distribution show some degree of morphological novelty (see Taxonomic Treatment). *Eucharis corynandra*, very closely related to *E. castelnaeana* and *E. plicata*, and *E. oxyandra*, of uncertain phylogenetic relationship, are both known only from the "ceja de la selva" forest formations of north-central eastern Peru. *Eucharis astrophiala* is endemic to a relatively small area of western Ecuador. *Eucharis lehmannii* and *E. caucana* are restricted to western Columbia. Of the five species, only *E. astrophiala* is known from other than the type locality.

Three of the four species of subg. *Eucharis* that occur above 2°N latitude are polyploids (chromosome number is unknown for *E. lehmannii*). *Eucharis bonplandii* ($2n = 92$), endemic to the Cordillera Oriental and Cordillera Central of Colombia is rare and infrequently collected. The *E. bouchei* complex ($2n = 92$), a series of geographically isolated and morphologically distinct population clusters (Meerow, 1987d), is endemic to Central America, chiefly Panama. *Eucharis caucana* is a hexaploid ($2n = 138$).

Subgenus *Heterocharis* is widely dispersed from Colombia to Peru, but each of its three species are narrowly distributed. With the exception of a single collection from northern Peru, *E. moorei* is not found outside of Ecuador. It is the only species of *Eucharis* found on both sides of the Andes. *Eucharis amazonica* occurs natively within a narrow area of the Río Huallaga valley in Peru. *Eucharis sanderi* is endemic to the Chocó region of Colombia.

Caliphruria is almost completely western Colombian, most prominently in the Río Cauca valley, with a secondary distribution in the Río Magdalena valley. *Caliphruria korsakoffii* is Peruvian.

ETHNOBOTANY

Labels of a number of herbarium specimens of *Eucharis* species indicate that lowland native people collect the bulbs for use as poultices. The bulbs are mashed, heated, and applied to sores and tumors. Lewis (1986) described the use of mucilage from *Eucharis* bulbs (the plant illustrated is *E. formosa*) by the Jivaro Indians of Peru for treating facial blemishes and acne. Indian women of the Pastaza valley in Ecuador reportedly quite actively collect the plants in flower for reasons they would not disclose (N. Whitten, pers. comm.). Most local inhabitants whom I met while collecting *Eucharis* in the Oriente were readily familiar with the plants when shown photographs.

That various neotropical Amaryllidaceae have been cultivated in their native countries for many years cannot be discounted. Motifs recognizable as species of *Zephryanthes* Herbert and *Stenomesson* Herbert appear on ceremonial Incan vases (Vargas, 1981). The seasonal mass-blooming of *Hymenocallis amancaes* (Ruíz & Pavón) Nichols. on the dry hills near Lima, Peru, has long been the nucleus of an annual festival named for that species (Herbert, 1839). I have suggested that frequent sympatric occurrence of *E. candida* and *E. formosa* in eastern Ecuador may have been influenced by cultivation by transient agriculturists (Meerow, 1987e). Further circumstantial evidence for this hypothesis is the persistence in nature of sterile hybrid taxa such as *E.* ×*grandiflora* and ×*Calicharis butcheri*. Almost all collections of the former are remnants of cultivation. *Eucharis oxyandra* is known only from bulbs found uprooted by an abandoned dwelling in Peruvian rain forest (see Taxonomic Treatment).

REPRODUCTIVE BIOLOGY

PHENOLOGY

Eucharis and *Caliphruria* species are largely seasonal flowering. Very well-collected species, such as *E. candida* or *E. formosa*, show flowering patterns skewed toward certain months (January to March), but at least several flowering collections have been made throughout the year. Species in Amazonian Peru have been collected in flower most frequently from June to September. Each inflorescence is moderately long-lived, two to three weeks, but usually no more than one to three flowers are open at any one time.

In the greenhouse, observations over a five-year period confirm an annual flowering for most *Eucharis* and *Caliphruria* species. *Eucharis amazonica*, however, flowers two or three times during the year. Van Bragt & Sprenkels (1983) have regularly induced flowering in this species at any time of the year after treatment at 27°C for at least two weeks. Collection data for this species

throughout its narrow range indicate that twice-annual phenology may occur in habitat as well. *Eucharis castelnaeana* mass-flowers in the greenhouse several times per year. Other well-collected species (e.g., *E. candida* and *E. formosa*) that show a peak period of flowering in certain months in nature are strictly annual-flowering in cultivation.

POLLINATION BIOLOGY

Data on pollination ecology of Amaryllidaceae in general are scant and represent an area sorely in need of investigation. No information on pollination of *Caliphruria* is available. The large, white, heavily and sweetly fragrant flower of *E. amazonica* (subg. *Heterocharis*) was considered a model moth-pollinated flower by Percival (1965). She noted that the nectar level in the tube rises to a maximum height of 23% tube length, thus effectively preventing access to all but long-tongued insects. The large, heavily fragrant flowers of subg. *Heterocharis* fit the syndrome of sphingid moth pollination (sensu Faegri & van der Pijl, 1979). Other related genera of "infrafamily" Pancratioidinae with similar flower morphology are specialized for hawkmoth pollination (*Hymenocallis*: Bauml, 1979; Grant, 1983; *Pancratium*: Morton, 1965).

Floral fragrance is rare in subg. *Eucharis*, occurring in only *E. bakeriana*, *E. castelnaeana*, *E. formosa*, and *E. plicata* subsp. *brevidentata*. However, floral fragrance is only weakly developed in these species, and in *E. formosa* the odor is slightly fetid. Vogel (1963) reported euglossine bees visiting *Eucharis bakeriana*. Visitation by an unidentified euglossine has been reported for other, unidentified species of subg. *Eucharis* in Peru (J. Schunke, pers. comm.). Unfortunately, neither report indicated the sex of the visitor. The phenology of *Eucharis* (rarely more than one or two flowers open per inflorescence at any one time over a period of two or three weeks, and the often successive appearance of inflorescences from a clonal clump of bulbs) and the dispersed distribution of plants in the wild suggests pollination by a trap-lining organism (see Janzen, 1971).

DISPERSAL

The leathery, bright orange fruit of *Eucharis* subg. *Eucharis* is a major apomorphy that defines the subgenus. At dehiscence, the contrast between the capsule and the lustrous black or blue seeds creates a striking visual display in the forest understory, but there are no recorded observations of visitation to the ripe capsules.

BREEDING SYSTEM

On the basis of greenhouse pollination attempts, virtually all species of *Eucharis* and *Caliphruria* demonstrate some degree of self-incompatibility. This observation suggests that most species are predominantly outcrossing. Capsules have been set readily with sibling pollen on all species in cultivation with the exception of *E. amazonica* and functionally sterile hybrid taxa (*E.* ×*grandiflora*, ×*Calicharis butcheri*). Further evidence of outcrossing is the marked protandry of most *Eucharis* species (with the exception of *E. castelnaeana*, in which stigma receptivity coincides with anthesis) and the presence of putative interspecific hybrids in nature (*E. candida* × *E. formosa* (Meerow, 1988), *E. plicata* subsp. *plicata* × *E. ulei* (Meerow, in prep.)). Of all species in cultivation, only *E. castelnaeana* sets capsules with self-pollen. Autogamy in *E. castelnaeana* is associated with a number of other divergent character states for subg. *Eucharis*. This species has a mass-flowering phenology; the smallest flowers in the genus; a green, often tardily dehiscent capsule; a less turgid seed with a dull, rugose testa; and telocentric chromosomes.

Reproductive biology of *Eucharis* and *Caliphruria* is thus still largely conjectural. Annual flowering patterns, short-term pollen viability, and susceptibility to systemic diseases in cultivation impede greenhouse exploration of these questions, and the rarity of the plants is an obstacle to field studies. The disappearance of populations of these genera and their pollinating agents, concurrent with rain forest destruction, may be the final impediment to investigation of this aspect of their biology.

Phylogenetic Relationships

Eucharis and *Caliphruria* have been variously treated as separate genera (Baker, 1888; Bentham & Hooker, 1883; Pax, 1888; Hutchinson, 1959), a single genus (Traub, 1963), and as subgenera of *Urceolina* (Traub, 1971). As a group, *Eucharis*, *Caliphruria*, and *Urceolina* appear to represent a distinct tribal assemblage within "infrafamily" Pancratioidinae Traub (1957, 1963), a group delimited by various patterns of staminal connation, somatic chromosome number frequently of $2n = 46$, and an Andean center of diversity (Meerow, 1985, 1986, 1987a, c).

PHYLOGENETIC ANALYSIS

Despite a lack of consensus on generic and specific limits in Amaryllidaceae, cladistic analysis has only twice before been applied to such problems

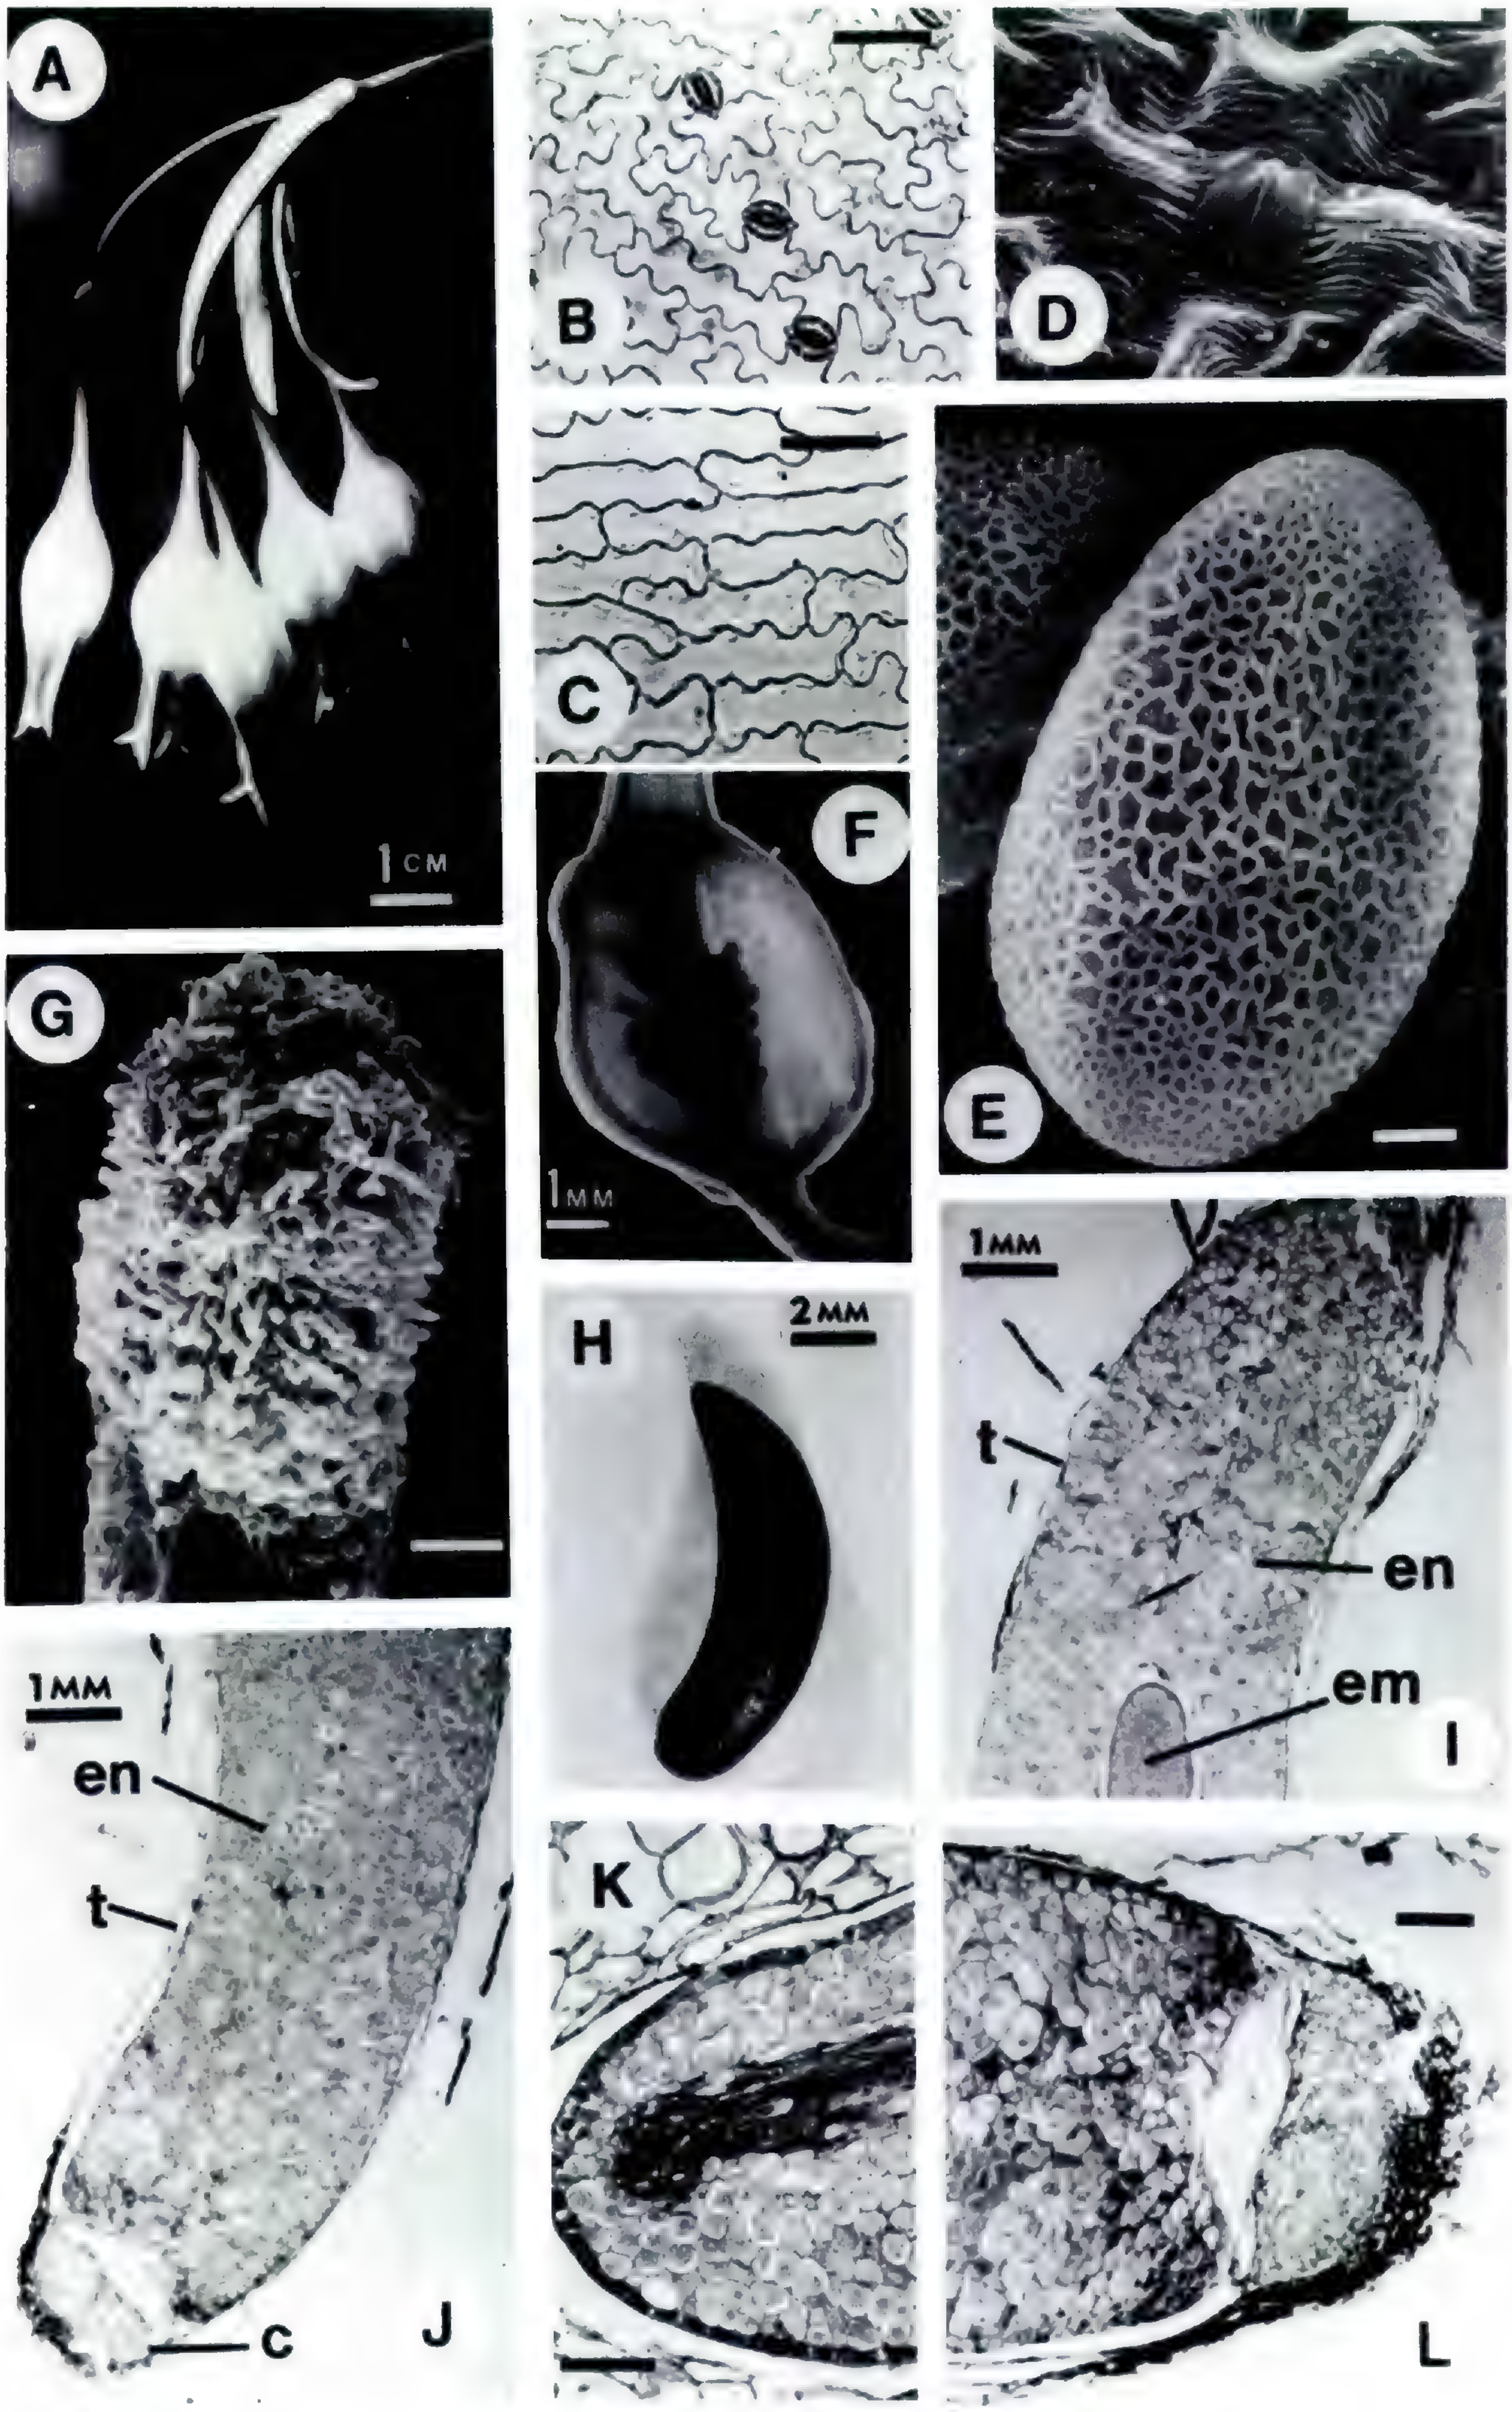


FIGURE 63. Character states of *Urceolina*. All photos are *U. microcrater* Kränzl. (*Schunke 13633*, FLAS) unless otherwise stated.—A. Flowers (*Plowman & Kennedy 5721*, GH). Photo courtesy T. Plowman. B, C. Leaf epidermal cell configurations.—B. Abaxial surface.—C. Adaxial surface.—D. SEM photomicrograph of abaxial leaf surface.—

in the family, by Nordal & Duncan (1984) for *Haemanthus* L. and *Scadoxus* Raf., two closely related, baccate-fruited African genera; and Meerow (1987c) for *Eucrosia* Ker Gawler. The generic limits of *Eucharis* and *Caliphruria* in relation to *Urceolina*, as well as interspecific relationships in the former genera, seemed two areas that would benefit from the application of cladistic analysis. Before assessing these relationships cladistically, a brief review of character states in *Urceolina* is necessary.

Urceolina (ca. 6–8 species; Fig. 63) is so far known only from central and southern Peru on the eastern Andean slopes (Fig. 64) at elevations of 700–2,000 m. The relationships of *Urceolina* have long been misunderstood, most workers (Baker, 1888; Pax, 1888; Hutchinson, 1959) placing *Urceolina* near *Stenomesson* Herbert. Traub (1957) was the first to recognize its affinities with *Eucharis*. The problem no doubt stemmed from the inclusion of a species of *Stenomesson* (*S. miniatum* (Herbert) Ravenna) in *Urceolina* as *U. miniata* (Herbert) Benth. & Hook. Despite the ventricose aspect of the corolla morphology of *S. miniatum*, which is similar to that of *Urceolina*, the species clearly belongs to *Stenomesson* as evidenced by its narrow, subpetiolate leaves, the morphology of its staminal cup, and its numerous flat, black seeds (Ravenna, 1978).

Urceolina is easily distinguished by its brightly colored, urceolate corolla formed by the coherence of the tepals throughout most of their length (Fig. 63A). Vargas (1960) described the genus *Pseudourceolina* to accommodate a species of *Urceolina* in which the tepals are supposedly more laxly coherent. The morphology of the flower in *Urceolina* strongly suggests ornithophily (sensu Faegri & van der Pijl, 1979), i.e., vivid, "parrot" colors, ventricose corolla, pendulous habit, and absence of odor. As in *Caliphruria*, the staminal cup of *Urceolina* is reduced to a minute, membranous, basal connation of the filaments, which are otherwise linear throughout their length. The leaves of *Urceolina*, in thickness and lack of both surface plication and marginal undulation, resemble *Caliphruria* more closely than *Eucharis*. At least one species is hysteranthous (*U. microcrater* Kränzlin), but all species enter a leafless dormant period in the wild. In size the pollen grains of *Urceolina* (Fig. 63E) are similar to those of *Caliphruria*. The coarseness of the reticulum is intermediate between that of *Eucharis* and *Caliphruria*. In all species of *Urceolina* the small stigma is capitate and entire (Fig. 63G) versus the trilobed stigma found in *Eucharis* and *Caliphruria*. *Urceolina* species have 10–20 ovules. The ripe fruit of *Urceolina* is a thin-walled, yellow-green, turbinate capsule. The seeds of *U. microcrater* (Fig. 63H) are narrowly oblong, ca. 8 mm long, and 2.5 mm wide, and curved. The seeds have a unique anatomical feature: at the chalazal end, a dam of poorly differentiated tissue separates a "cap" composed of many small cells from the endosperm (Fig. 63J, L). The cells of the "cap" do not have pitted walls with plasmodesmata as is characteristic of the endosperm cells. There is no obvious surface feature on the seed corresponding to the area of this "cap," and its function is unknown.

Outgroup selection. Preliminary cladistic analyses of the pancratioid Amaryllidaceae (Meerow, 1985) indicate that within the Pancratioidinae, a large, white, fragrant, crateriform flower with a conspicuous staminal cup ("pancratioid," cf. *Pancratium* L.), involved with sphingid moth pollination (Bauml, 1979; Grant, 1983; Morton, 1965), may be symplesiomorphous. In other words, while the pancratioid flower was a major apomorphy defining the Pancratioidinae as a distinct group within the Amaryllidaceae, it is the ancestral floral morphology from which all other pancratioid taxa have diverged. I have used the term "the pancratioid base" to define the five genera of Pancratioidinae with this type of flower morphology (Meerow, 1985). These five genera are *Eucharis*, *Hymenocallis*, *Pancratium*, *Pamianthe* Stapf, and *Paramongaia* Velarde. All but *Pancratium* are entirely neotropical in distribution. The pancratioid flower correlates repeatedly with the largest pollen grain size within the Pancratioidinae (Meerow, 1985; Meerow & Dehgan, 1985). Putatively basal complexes within each pancratioid lineage also have numerous ovules per locule (ca. 20 or more), a character state considered primitive in the Amaryllidaceae (Traub, 1963).

Pollen morphology provides the best evidence for the monophyly of the Pancratioidinae. The large pollen grains of most species of the pancratioid base are uniformly coarsely reticulate, with some in each genus exhibiting a striking exine

dimorphism at the equatorial ends of the grain (Meerow, 1985; Meerow & Dehgan, 1985). Nonetheless, separate origins of the pancratioid flower in the Neo- and Paleotropics cannot be ruled out.

That the neotropical tribes of the Pancratioidinae represent a monophyletic group is a much more robust hypothesis. All neotropical pancratioid genera have $2n = 46$ as the most common somatic chromosome number (Di Fulvio, 1973; Flory, 1977; Meerow, 1985, 1987a, c; Williams, 1981). This number may be derived from $2n = 22$, the most common somatic chromosome number in the family

(Flory, 1977; Goldblatt, 1976; Meerow, 1984) via duplication or fragmentation of a chromosome, followed by doubling of the genome (Lakshmi, 1978; Sato, 1938). All paleotropical pancratioid genera have 22 or 20 chromosomes (Ponnamma, 1978; Zaman & Chakraborty, 1974).

Pancratium (ca. 17 species) and two species of *Hymenocallis* (*H. quitoensis* Herbert and *H. heliantha* Ravenna) were used as the primary outgroups in the analyses presented. Character state data on these taxa were accumulated from study of living material, herbarium specimens and literature (Björnstad, 1973; Meerow & Dehgan, 1985; Morton, 1965; Ponnamma, 1978; Ravenna, 1980; Traub, 1962; Werker & Fahn, 1975). *Pancratium* is putatively the least derived genus of the pancratioid base (Meerow, 1985). It is the only paleotropical genus of the group, and the only member with $2n = 22$ (Ponnamma, 1978), considered by most workers as the ancestral somatic chromosome number in the family (Flory, 1977; Goldblatt, 1976; Meerow, 1984).

The two species of *Hymenocallis* are undoubtedly a monophyletic group. They are the only two

species of *Hymenocallis* with phytomelanous seed coats. All evidence suggests that possession of phytomelan is the ancestral condition in the Amaryllidaceae, and despite several independent losses, no reversal to the ancestral state has been proposed (Dahlgren & Clifford, 1982; Dahlgren & Rasmussen, 1983; Dahlgren et al., 1985; Huber, 1969). *Hymenocallis quitoensis* was segregated into a separate genus, *Lepidochiton* Sealy (1937) on the basis of phytomelanous seed. Both *H. quitoensis* and *H. heliantha* are ephemeral components of the xeric flora of southwestern Ecuador and northwestern Peru, and differ only in flower color. Traub (1962) considered *H. quitoensis* a relict and the most primitive species of *Hymenocallis* on the basis of ovule number (ca. 20 per locule; 2–10 occurs in all other species) and chromosome number ($2n = 24$, based on Snoad, 1952); however, collections from Peru and Ecuador that I have examined have $2n = 34$. These are the lowest reported chromosome numbers in the genus (Flory, 1976). These species will be called *Lepidochiton* in the following discussion. Additional analyses were run using other members of the pancratioid base as outgroups (*Hymenocallis* subg. *Hymenocallis*, *H.* subg. *Ismene* (Salisb.) Baker ex Traub, *Pamianthe*, and *Paramongaia*). The resulting cladograms were either equal in length or slightly less parsimonious than those presented here; they did not show changes in the resolution of terminal taxa from the cladograms presented.

Ordered characters. Ten of the 18 multistate characters (Table 2) used in these analyses (8, 9, 10, 13, 24, 25, 27, 28, 30, and 35) were ordered into linear transformation series. Study of character state correlations among all genera of the pancratioid Amaryllidaceae (Meerow, 1985, 1987a, c) strongly suggests that flower size reduction (8), loss of floral fragrance (9), flower number (10), pedicel length (13), staminal tooth length (25), style length (30), and reduction in ovule number (35) have evolved in this stepwise manner with no evidence of reversal. Numerous ovules per locule (20 or more) characterizes all basal genera of the pancratioid Amaryllidaceae and is generally considered the ancestral condition for the family (Traub, 1962, 1963; Traub & Moldenke, 1949). Though the

evidence from phenetic studies of *Eucharis* (Meerow, 1987d, in press) and from study of other genera of the pancratioid Amaryllidaceae (e.g., Meerow, 1987c) indicates that androecial characters are among the most plastic morphological characters in this group, examination of the evolutionary patterns of staminal dentation (24) within various genera (Meerow, 1987c, in press) suggests that a reversal to the dentate state is unlikely once dentation is lost completely. Complete loss of staminal dentation often accompanies overall phenetic divergence among the pancratioid genera (Meerow, 1985, 1987c; see *E. astrophiala* in this paper). Polymorphism for the character is not uncommon, however, and is conceived in the transformation series as the intermediate between the two fixed states of toothed or edentate stamens. Ordering of pollen size (27) and exine morphology (28) is based on data presented in Meerow (1985, 1987c) and Meerow & Dehgan (1985), as well as unpublished palynological data accumulated for many genera in the family. A single character, chromosome number (41), was coded in additive binary on the basis of much literature on amaryllid cytology (Flory, 1976, 1977; Goldblatt, 1976; Lakshmi, 1978; Meerow, 1984, 1987b; Ponnamma, 1978; Sato, 1938; Snoad, 1952), which strongly supports this concept of chromosome number evolution.

Results and discussion. Twelve most parsimonious trees without any differences in topology resulted when either *Pancratium* or *Lepidochiton* was used as the outgroup. The twelve trees differed only in the branch lengths of a few internal nodes, and resolution of terminal taxa did not change among them. One of the twelve with *Pancratium* used as outgroup is illustrated and discussed in detail (Fig. 65). The cladogram has a length of 92.4 steps (fractional lengths are a result of weight scaling), and a consistency index (CI; Kluge & Farris, 1969) of 0.487. *Lepidochiton* is the first terminal EU to resolve in the cladogram after the outgroup, *Pancratium*. Character state changes from the outgroup to the ancestral node of *Lepidochiton* (flower number reduction, globose seeds) could not be polarized. Uniflory, perianth color polymorphism, brown seed testa, and $2n = 34$ are the four apomorphies of *Lepidochiton*. The next internal node of the cladogram is the hypothetical ancestor to *Eucharis*, *Caliphruria*, and *Urceolina*,

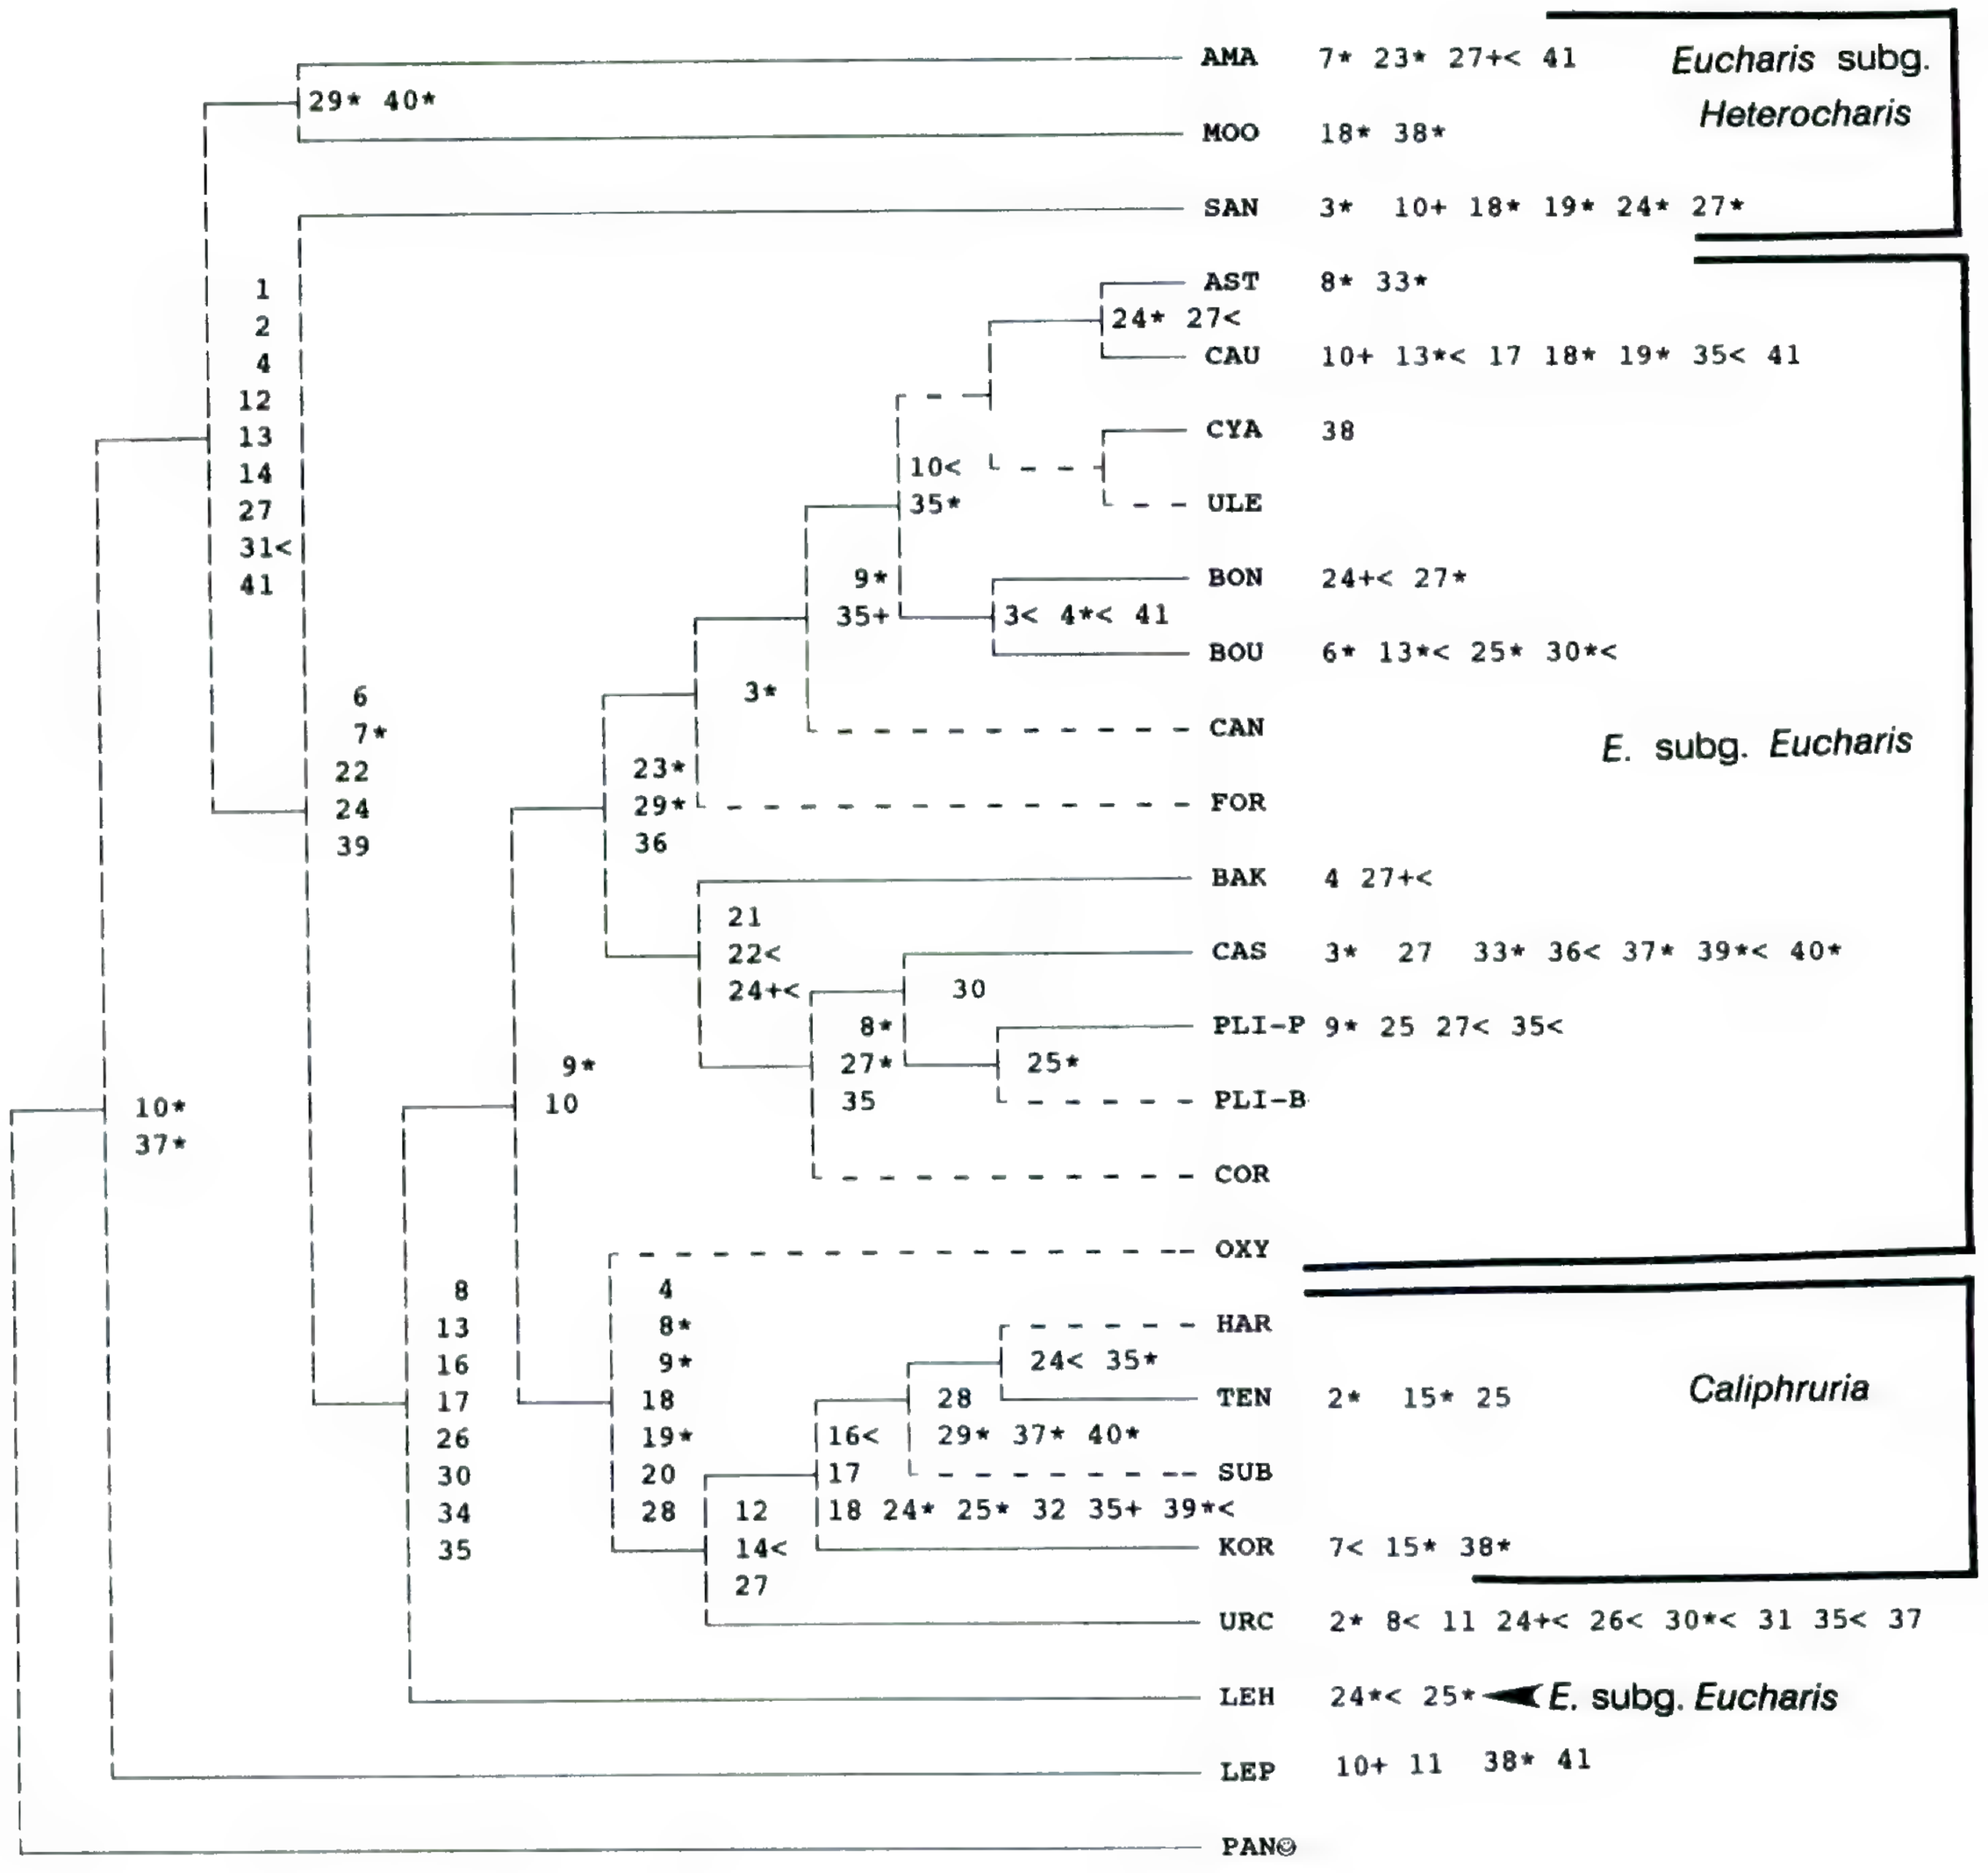

FIGURE 65. Cladogram of *Eucharis* and *Caliphruria*, based on data matrix in Table 3. Broken horizontal line indicates zero-length branch. Numbers inside refer to apomorphies of adjacent EU or internal node. Refer to Table 1 for EU designations.

all of which thus form a monophyletic group. Nine apomorphies occur at this node. The most important are the evolution and fixation of the evergreen, petiolate leaf; the changes in flower habit, pedicel length, tube morphology, and pollen size; trilobed stigmas; and increased chromosome number.

The rest of the cladogram forms two monophyletic groups. The smaller group represents part of my concept of subg. *Heterocharis*, *E. amazonica* and *E. moorei*, linked by three apomorphies: secondary petiolar bundles, loss of pollen exine dimorphism, and rugose testa (the state for the last-mentioned character is unknown for *E. amazonica*). The larger monophyletic group represents *E. sanderi*, *Eucharis* subg. *Eucharis*, *Caliphruria*, and *Urceolina*. Five apomorphies define the ancestral node: densely striate abaxial cuticle, undulate anticlinal walls (homoplasious with *E. amazonica*), deeply cleft staminal cup, polymorphism in staminal dentation, and lustrous testa. It is thus obvious that subg. *Heterocharis* is paraphyletic according to this cladogram. *Eucharis moorei* and *E. amazonica* also resolve cladistically as the most basal species of *Eucharis*.

Eucharis sanderi is cladistically basal to the remaining EUs with which it forms a monophyletic

group. The six apomorphies of *E. sanderi* are plicate leaves, reduction in flower number, campanulate perianth (homoplasious with *E. moorei*), reduced staminal cup, loss of staminal dentation, and yet further reduced pollen grain size.

The next monophyletic group is supported by eight apomorphies and comprises *Eucharis* subg. *Eucharis*, *Caliphruria*, and *Urceolina*. Apomorphies at the ancestral node are reduced flower size, increased pedicel length, loss of green tube pigmentation, change in tube dilation, erect anthers, decreased style exsertion, nonrostellate ovary, and decreased ovule number. *Eucharis lehmannii* is cladistically basal to the remaining EUs in the cladogram and is defined by two apomorphies: a reversal to dentate stamens and an increase in the length of the teeth. The remainder of the cladogram forms two monophyletic groups. All but two species of *Eucharis* subg. *Eucharis* comprise one, and *Caliphruria*, *Urceolina*, and *E. oxyandra* constitute the second. Only two apomorphies define this clade: reduction in floral fragrance and an increase in flower number.

The three apomorphies at the ancestral node of the *Eucharis* subg. *Eucharis* clade are subulate free filaments (homoplasious with *E. amazonica*), loss of exine dimorphism (homoplasious with the ancestor of *E. amazonica* and *E. moorei*), and an orange capsule. Within this clade, two monophyletic groups are evident. The larger of the two is defined by a single apomorphy, plicate leaves. *Eucharis formosa* is the first terminal EU to resolve but terminates a zero-length branch. *Eucharis candida* also terminates a zero-length branch, the ancestral node of which is defined by two apomorphies: loss of floral fragrance and reduction in ovule number. The next monophyletic group encompasses all species of subg. *Eucharis* with about five flowers and about two ovules per locule. The hypothetical ancestor of *Eucharis astrophiala* and *E. caucana* forms an unresolved polytomy at the ancestral node with *E. cyaneosperma*, *E. ulei*, and the hypothetical ancestor of tetraploid species *E. bonplandii* and *E. bouchei*.

Three apomorphies define the ancestral node of the second clade within subg. *Eucharis*: a plicate staminal cup, a reversal to shallowly cleft staminal cups, and a reversal from polymorphism in staminal dentation to fixed dentation. *Eucharis bakeriana* is the first terminal EU to resolve, on the basis of two apomorphies: loss of leaf margin undulation and increase in pollen size. The remaining species are the smallest-flowered species in the subgenus. The remaining apomorphies at the ancestral node are a decrease in pollen size and ovule number. The first terminal EU to resolve is *E. corynandra*, from a zero-length branch. It should be noted, however, that two autapomorphies of this species, a short staminal cup and club-shaped free filaments, were not included in the data matrix. The ancestor of the two subspecies of *E. plicata* form a monophyletic group with *E. castelnaeana* on the basis of style length. Subspecies *brevidentata* terminates a zero-length branch. *Eucharis castelnaeana* has the greatest patristic distance of the three EUs (seven apomorphies).

The final large clade constitutes *Caliphruria*, *Urceolina*, and the cladistically basal *E. oxyandra*. Apomorphies are nonundulate leaf margins, small flowers, loss of floral fragrance, urceolate corolla (which does not apply to *E. oxyandra*, the corolla shape of which is either crateriform or campanulate but could not be coded as one or the other with certainty), reduction of the staminal cup, loss of androecial pigmentation, and moderately coarse exine. The character state of *E. oxyandra* is unknown for four of these seven. Within this monophyletic group, *Urceolina* and the hypothetical ancestor of *Caliphruria* resolve as sister groups on the basis of three apomorphies: declinate or pendent flowers via pedicel habit, straight tubes, and small pollen grains. Nine and eight apomorphies define *Urceolina* and the hypothetical ancestor of *Caliphruria*, respectively. Within *Caliphruria*, the sole representative of the genus outside Colombia, *C. korsakoffii* is the first terminal EU to resolve, on the basis of three apomorphies: straight anticlinal epidermal walls, short tubes (homoplasious with *C. tenera*), and brown testa. *Caliphruria subedentata* terminates a zero-length branch from the hypothetical ancestor of the Colombian species of the genus. Apomorphies at the ancestral node are finely reticulate exines, loss of exine dimorphism, compressed seeds, and rugose testa (the states for the last two characters are known only for *C. subedentata*). *Caliphruria hartwegiana* and *C. tenera* form a monophyletic group on the basis of toothed stamens and reduced ovule number, but *C. hartwegiana* terminates a zero-length branch.

The cladogram presented in Figure 65 contains 70 parallel origins of character states and 29 reversals (unordered characters not included). This may raise questions concerning the homology of characters that manifest low consistency. If the data matrix is analyzed with all characters removed that exhibit three or more independent origins for the same state (characters 3, 4, 8, 9, 10, 18, 19, 24, 25, 27, 29, 35, 37, 38, 40), the three trees that result have a fourfold increase in zero-length

branches and unresolved polytomies. Invariably, it is androecial characters (including pollen size) in which a great deal of homoplasy has occurred. Three of all the androecial characters, 24 (staminal dentation), 25 (length of teeth), and 27 (pollen size), are particularly homoplasious. When the data matrix was run with only these characters deleted, no change occurred in the resolution of terminal taxa from the cladogram in Figure 65. Finally, the data matrix was analyzed with all staminal cup characters (19, 20, 21, 22, 23, 24, 25), and pollen size (27) deleted. The resulting three cladograms (differing only by one internal branch length) placed *Caliphruria* and *Urceolina* within a monophyletic group including *E. bakeriana*, *E. bonplandii*, and *E. bouchei*, on the basis of a single apomorphy, nonundulate leaf margins.

Regardless of how the character-state data are manipulated, a number of monophyletic groups appear particularly robust. That *Eucharis*, *Caliphruria*, and *Urceolina* represent a monophyletic group is uncontested. The monophyly of *Eucharis moorei* and *E. amazonica* is also strongly supported, and these two species are the most cladistically basal of the eucharoid lineage. These species have the greatest number of putatively primitive characters and seem to represent the more ancestral species in the genus. Nonetheless, according to the cladogram in Figure 65, retaining subg. *Heterocharis* in *Eucharis* renders the genus paraphyletic. Subgenus *Heterocharis* is a fairly heterogeneous group from the perspective of apomorphic characters alone. Each of the three species may be characterized by autapomorphies, but only plesiomorphies join them. By including subg. *Heterocharis* in *Eucharis*, *Eucharis* becomes paraphyletic according to this cladogram. However, it should be noted that it is unknown whether secondary petiolar bundles (which require fresh material to observe), an important apomorphy which links *E. amazonica* and *E. moorei*, are present in *E. sanderi*. In the generalized sense, the distribution of subg. *Heterocharis* is quite broad, from Colombia to Peru (Fig. 64). However, each of the three species of subg. *Heterocharis* itself are only narrowly distributed. *Eucharis sanderi* is known only from the Chocó region of Colombia. *Eucharis amazonica* is found natively only in the middle Río Huallaga valley of Peru. *Eucharis moorei* has been collected outside of Ecuador only once. More significantly, *E. moorei* is the only species of *Eucharis* found on both sides of the Andes. I believe that all three species of subg. *Heterocharis* represent the relictual remnants of the ancestral eucharoid complex, each of which has remained isolated long enough to evolve its respective cohort of autapomorphies.

The sister group relationship between *Urceolina* and *Caliphruria* also seems to be a robust cladistic hypothesis, with *E. oxyandra* potentially ancestral to both. *Eucharis oxyandra* is a taxonomically perplexing species in its characters of morphological intermediacy (androecium and pollen morphology) between *Eucharis* and *Urceolina*. it is known only from bulbs found in local, transient cultivation in Peru, near the single recorded point of geographic sympatry between *Eucharis* (*E. amazonica*) and *Urceolina* (*U. microcrater*). The absence of much character state data, but particularly those on fruit and seed morphology, further occludes resolution of its phylogeny, and any of several hypotheses concerning its origins are possible (see Taxonomic Treatment). *Eucharis lehmannii*, which usually resolves within a cladistic "no man's land" between paraphyletic subg. *Heterocharis* and all other clades, presents a similar problem, though Regel's (1889) figure strongly suggests affinity to subg. *Eucharis*. In the initial analyses, in which all multistate characters were treated as unordered, this poorly known species resolved as sister group to *E. bouchei*. I believe that *E. lehmannii* is a sister species to *E. caucana*, to which it bears much phenetic resemblance, and that its unusual resolution in the cladogram is a result of the great deal of missing character state data. Fruit and seed morphology clearly place *E. caucana* in subg. *Eucharis*, even though it shows as much novelty as *E. oxyandra* or *E. lehmannii* in other characters.

Excluding *E. lehmannii* and *E. oxyandra*, *Eucharis* subg. *Eucharis* forms another clearly monophyletic group. Species with five flowers and two ovules per locule (*E. astrophiala*, *E. cyaneosperma*, *E. ulei*, along with the tetraploids, *E. bonplandii* and *E. bouchei*) form a very natural group with karyotypic similarity as well (Meerow, 1987b). The sister species relationship of *Eucharis caucana* to *E. astrophiala* within this group may be as equivocal as the basal resolution of *E. lehmannii*, since it is based on two apomorphies (pollen size and lack of staminal dentation), the latter of which is highly homoplasious. I believe the reversal in ovule number necessary for *E. caucana* to share common ancestry with *E. astrophiala* is very unlikely.

Eucharis candida and *E. formosa*, two often sympatric (and possibly sibling) species, are cladistically close and basal to the five-flowered clade. The small-flowered species (*E. castelnaeana*, *E. corynandra*, and *E. plicata*) form another very

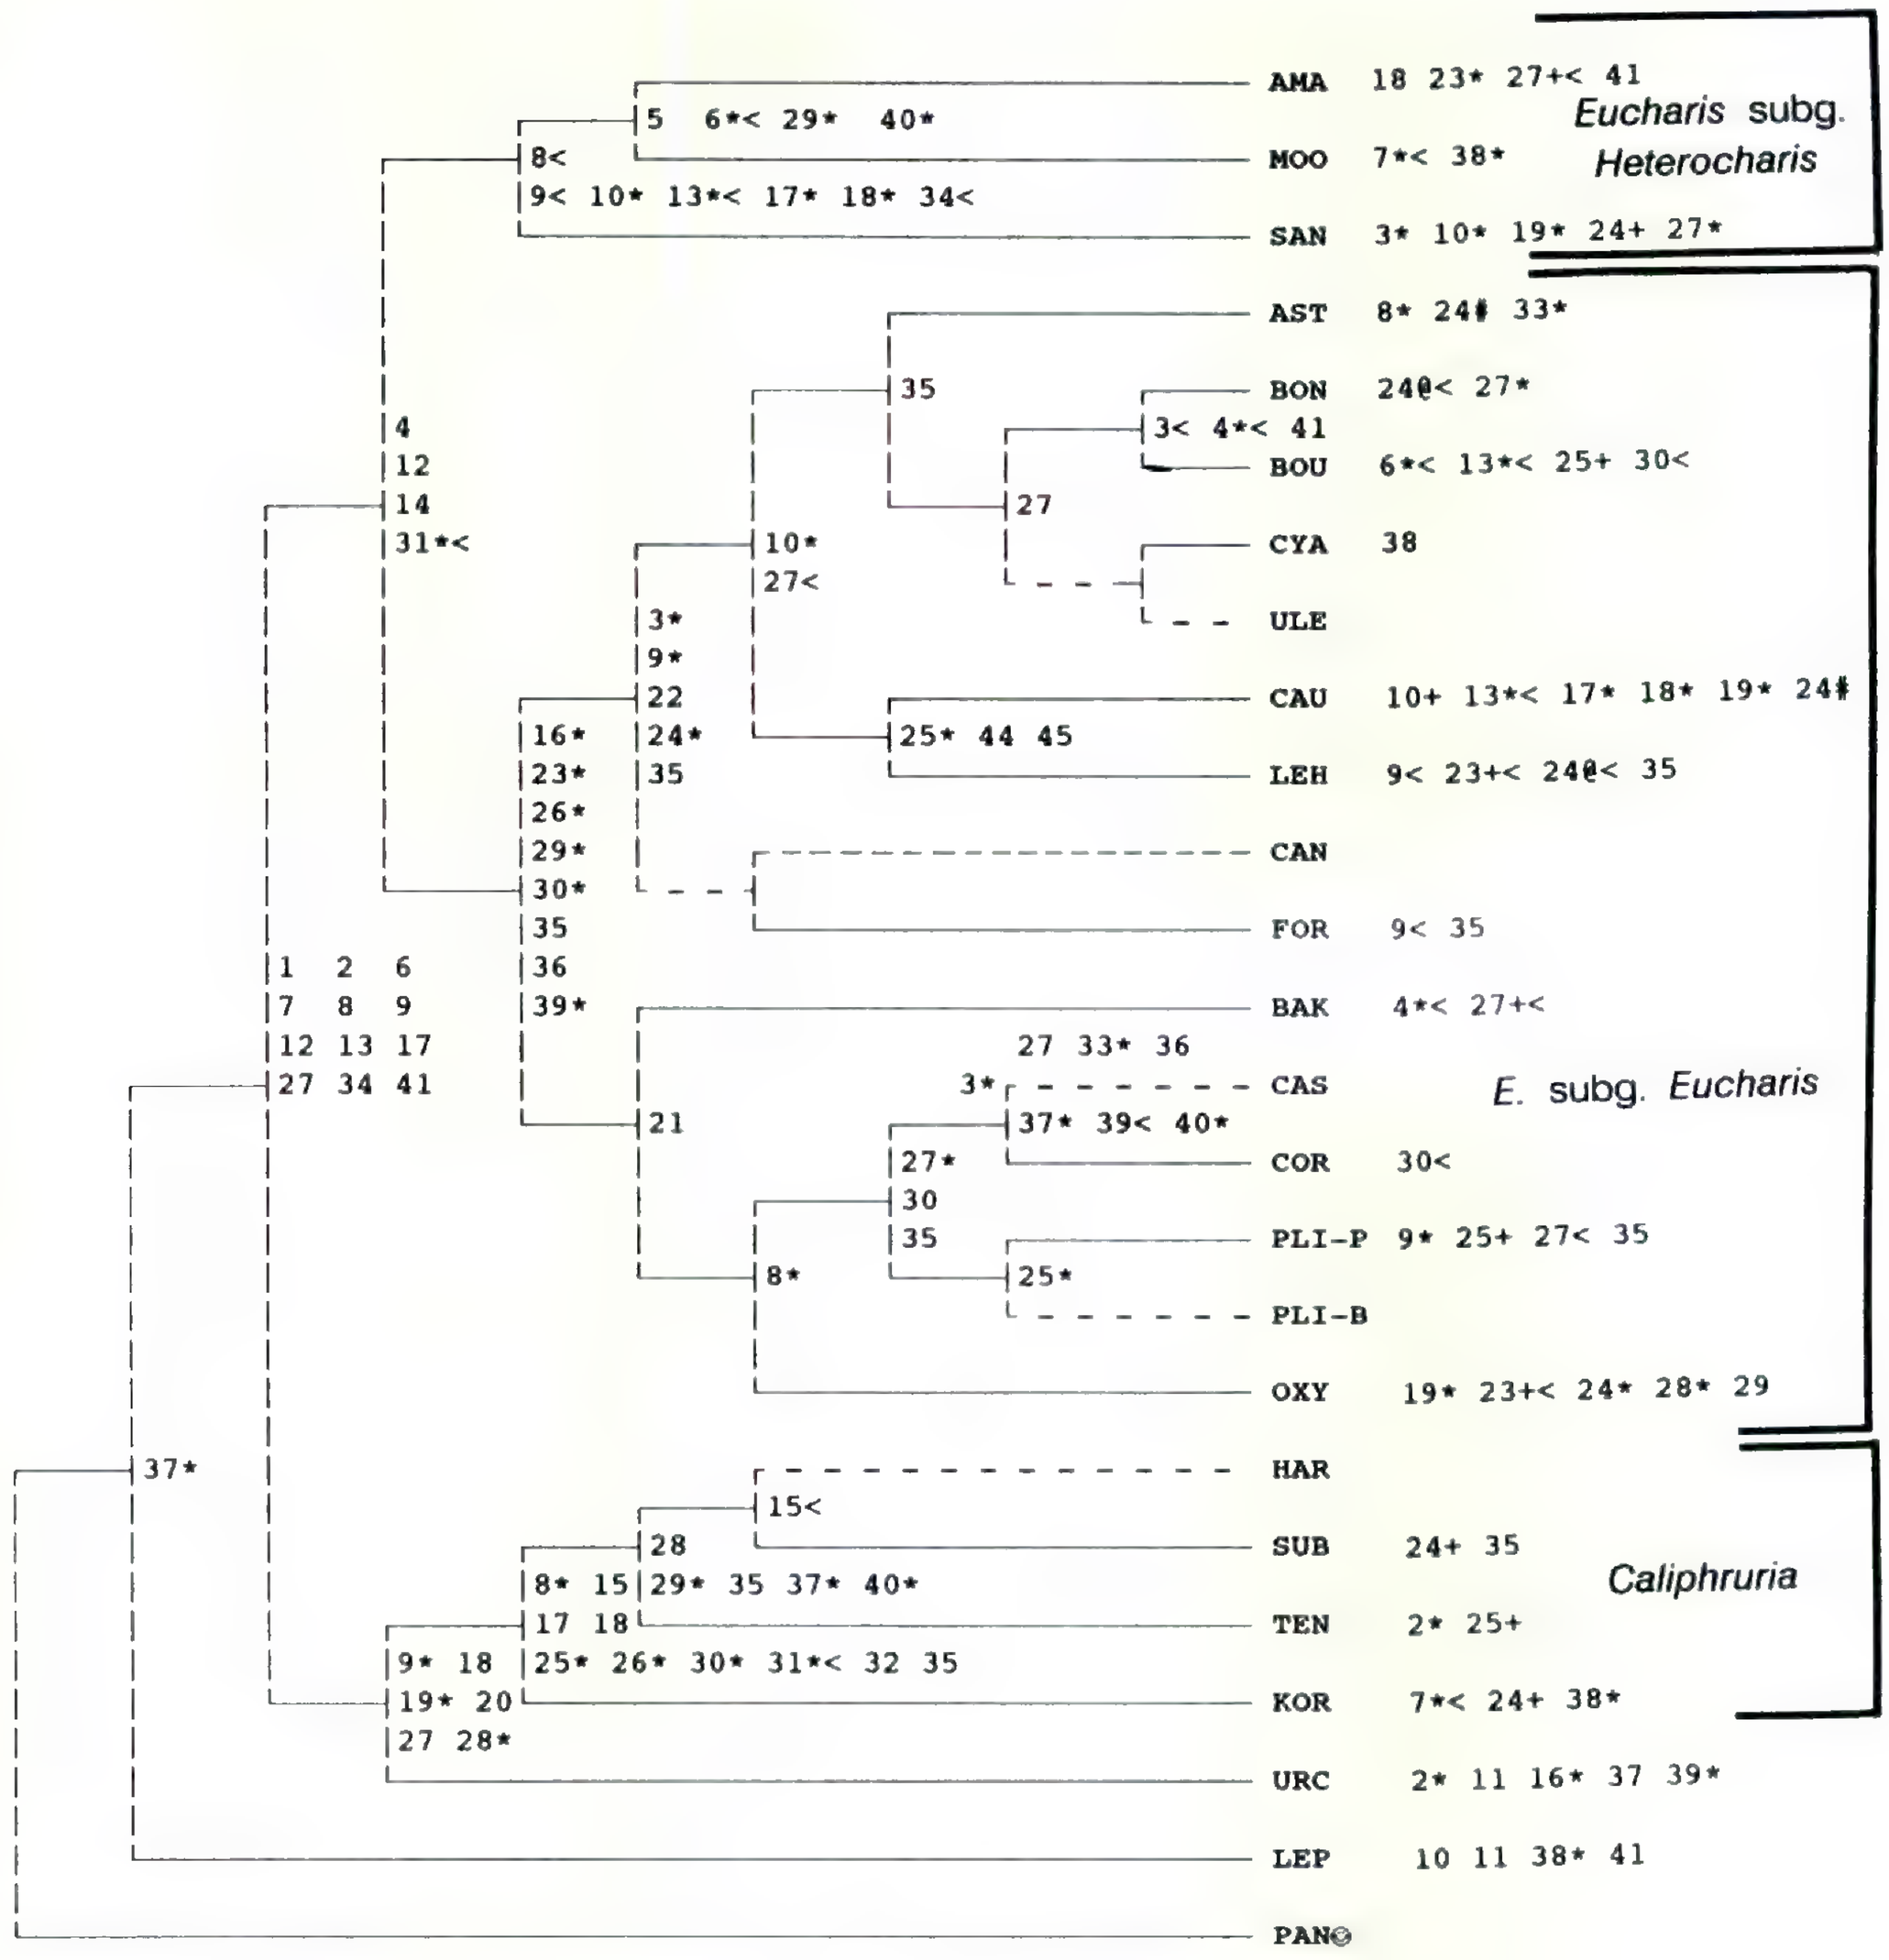

FIGURE 66. User-generated cladogram of *Eucharis* and *Caliphruria*. Broken horizontal line indicates zero-length branch. Numbers inside refer to apomorphies of adjacent EU or internal node. Refer to Table 1 for EU designations.

natural group. The position of *E. bakeriana* as basal to this clade, largely on the basis of a plicate staminal cup, may be equivocal. Karyotype analysis (Meerow, 1987b) suggests putative relationship of *E. bakeriana* to *E. formosa*.

An alternative hypothesis of phylogenetic relationship is presented in Figure 66. The cladogram is a user-generated tree in which *Caliphruria* and *Urceolina* are placed as sister groups to a monophyletic *Eucharis*. The topology of subg. *Eucharis* in this cladogram represents my concepts of their evolutionary relationships based on phenetic resemblance, phytogeography, and chromosome data. The major differences from the cladogram in Figure 65 are the sister species relationship of *E. caucana* and *E. lehmannii*, the ancestral node of which forms a monophyletic group with the five-flowered, two-ovuled species complex; and the positioning of *E. oxyandra* as part of the small-flowered species group of subg. *Eucharis*. This user-generated cladogram had a length of 100.6 steps, with a CI of 0.443. There are 82 parallelisms represented among the character state changes, and 29 reversals. The user-generated tree (Fig. 66) is thus somewhat less parsimonious than the cladogram in Figure 65. Of particular interest in the user-gen-

erated cladogram is the resolution of the larger monophyletic groups constituting genera or subgenera, and the accompanying character state changes within these clades.

In Figure 66, a monophyletic subg. *Heterocharis* is supported by seven apomorphies, four of which are reversals (unordered characters not counted). Some of these reversals are very unlikely (e.g., reversal to larger, heavily fragrant flowers; see previous discussion of ordered characters) and would thus represent retention of ancestral states.

In the user-generated tree, a monophyletic subg. *Eucharis* is supported by a greater number of apomorphies (eight in Fig. 66) than in the parsimony cladogram (three). *Caliphruria* as a monophyletic group is best supported by Figure 66 (ten apomorphies) versus eight in Figure 65.

The results of these various cladistic treatments illuminate the problems inherent in phylogenetic reconstruction of large, "messy" character state data sets, and particularly with taxa whose evolution has involved large-scale homoplasy. The user-generated cladogram in Figure 66 represents my preferred hypothesis of phylogeny within the *Eucharideae*; nonetheless I cannot deny the compelling evidence that *Eucharis*, by the inclusion of subg. *Heterocharis*, may be paraphyletic.

From an orthodox cladistic perspective (Wiley, 1981), Traub's (1971) concept of a single polymorphic genus, *Urceolina*, is supported by the criterion of parsimony. From a phenetic (and pragmatic) standpoint, I find this unsatisfactory due to the close phenetic relationship between subg. *Heterocharis* and *Eucharis*. This relationship is most conspicuous if one compares *Eucharis bakeriana* and *E. formosa* (the most basal species of subg. *Eucharis*) with *E. amazonica* and *E. moorei* (subg. *Heterocharis*). I prefer to recognize *Urceolina* and *Caliphruria* as distinct genera, despite the attendant risk of a paraphyletic *Eucharis*. I do not believe that *Urceolina* and *Caliphruria* necessarily share an immediate common ancestor—the three apomorphies that define their sister group relationship in Figure 65 (reversal to straight tubes, flower habit, and smaller pollen grains) are homoplasious within the *Eucharideae* as well as in other tribes of the Pancratioidinae (Meerow, 1987c; Meerow & Dehgan, 1985). Until further data allow a more accurate understanding of their relationships, I also prefer to maintain *E. lehmannii* and *E. oxyandra* as species of *Eucharis* subg. *Eucharis*, allied with the small-flowered species with numerous ovules per locule. Without study of living material, and particularly knowledge of fruit characters, I am unwilling to declare *E. oxyandra* a sister taxon to *Urceolina* and *Caliphruria*.

Ashlock (1971, 1972, 1979, 1984) has repeatedly argued for the acceptance of paraphyletic groups in evolutionary systematic classifications. He defined two subclasses of monophyletic groups: holophyletic, which contain all descendents of the stem ancestor, and paraphyletic, those which do not. Ashlock (1979: 449) rejected "the automatic conversion of the cladogram into a classification." Meacham & Duncan (1987) have elaborated on the term "convexity," first proposed by Estabrook (1978), which attempts to resolve the concepts of monophyly, holophyly, and paraphyly. Meacham & Duncan concluded that Ashlock's (1979) advocation of overall evolutionary similarity as a component of classification schemes, rather than strict cladistic topology alone, is sound, and they discussed the mitigating factors surrounding cladistic methodology (e.g., uncertainty of character state polarities, the speculative nature of phylogenetic reconstructions, among others) which compromise a direct translation of cladogram into classification. A similar argument was recently articulated by Cronquist (1987). Donoghue & Cantino (1988) and Humphries & Chappill (1988) have responded vociferously to Cronquist's (1987) critique. Donoghue & Cantino (1988: 108) assail paraphyletic higher taxa as "artificial classes created by taxonomists who wish to emphasize phenetic 'gaps', and that formal recognition of such taxa conveys a misleading picture of common ancestry and character evolution."

The enormous amount of homoplasy evident within the highly canalized Amaryllidaceae creates great difficulty in phylogenetic reconstruction (Meerow, 1985, 1987c). In the analyses of *Eucharis* and related genera, missing character state data further weaken the argument for adopting ad hoc the most parsimonious phylogeny as the basis for classification. At present, I prefer to accept a less parsimonious phylogeny as represented by the user-generated topology in Figure 66 until such time as cladograms can be generated with consistency indices greater than 0.5. Towards this end, work is continuing with careful application of selected character weighting (Neff, 1986; Wheeler, 1986).

In three neotropical lineages of the Pancratioidinae, parallel trends in the evolution of floral morphology have occurred (Meerow, 1985, 1987c). In each case, taxa with smaller, tubular or ventricose, brightly colored flowers with reduced staminal connation, and without noticeable fragrance

have apparently diverged from taxa possessing a large, white, fragrant, crateriform flower with a staminal cup (Meerow, 1985, 1987c). Each lineage appears to be a monophyletic group on the basis of vegetative and ovarian morphology, as well as chromosome number (Meerow, 1985, 1987c; Traub, 1963). A similar pattern occurs in all three lineages: 1) floral morphology of "derived" taxa suggests an ornithophilous pollination syndrome, and 2) "derived" taxa are found, entirely or in part, at higher elevations than apparent ancestral taxa. *Eucharis* and *Urceolina*, as documented in this paper, present one such case. *Pseudostenomesson* Velarde, submerged by Traub (1980) into *Hymenocallis* as section *Artema*, presents a parallel situation within the *Hymenocallis* lineage (Meerow, 1985; Meerow & Dehgan, 1985). Tribe *Stenomesseae* contains two small genera, *Pamianthe* and *Paramongaia*, with ancestral floral morphology and contains a large genus, *Stenomesson*, with derived morphology (Meerow, 1987c). In the *Hymenocallis* and *Eucharis* lineages, the pancratioid floral morphology has radiated to a far greater extent than the putatively ornithophilous divergence (*Pseudostenomesson* and *Urceolina*, respectively). In the *Pamianthe–Paramongaia/Stenomesson* lineage, the derived genus, *Stenomesson* (35–40 species), has speciated to a greater degree than taxa with the ancestral pancratioid flower (*Pamianthe*: 2 species, *Paramongaia*: monotypic).

The high level of divergence in neotropical pancratioid tribes may be primarily a factor of two causes, 1) the uplift of the Andes in the Pliocene (van der Hammen, 1974, 1979), creating much opportunity for geographic isolation, and 2) greater genetic adaptability via tetraploidy to new ecological zones. The occurrence of rare hybridization in nature between the relict complex represented by *Eucharis* subg. *Heterocharis* and both *Caliphruria* (×*Calicharis butcheri*) and *Urceolina* (×*Urceocharis edentata*) may be further indication that the evolution of these genera was geologically recent.

Taxonomic Treatment

subspecific taxa

The rank of subspecies is used once in this treatment (*E. plicata*) to designate strong morphological divergence coupled with geographical isolation that I accept within specific limits. The rank of variety is used in a case (*E. bouchei*) where both the morphological and geographic components of divergence are weaker but appear to represent the first stages of speciation within a tetraploid semispecies complex (Meerow, 1987d).

critical measurements

Measurements of vegetative and floral parts in the following species descriptions are derived from examination of dried material (floral parts after rehydration in 3% solution of Aerosol OT brought to boil) supplemented with examination of fresh or FAA-preserved material when available. I found less than 5% difference between measurements of dried and fresh or spirit-preserved material of the same collection when available.

a note on the keys

Species of *Caliphruria* and *Eucharis* subg. *Heterocharis* are separable by discrete characters very amenable to key construction. Using the keys to these two groups, any worker should be able to identify material referable to described taxa whether in the field or the herbarium. The enormous degree of variation exhibited by species of subg. *Eucharis*, however, made key construction difficult. A number of the species overlap to at least some degree with one or more other species in virtually all quantitative morphological characters. As a consequence, sometimes I have had to rely on characters observable only with living material. With perseverance, it should be possible to key out all but the most depauperate herbarium specimens of subg. *Eucharis*. Collectors should note such characters as leaf plication and undulation, floral fragrance, tepal habit, and pigmentation and plication of the staminal cup in their notes when preparing specimens of *Eucharis*.

key to *Eucharis* and *Caliphruria*

1a. Leaf margins usually undulate; flowers declinate to pendulous via the curving of the tube; perianth funnelform-campanulate or crateriform; tube cylindrical, at least below middle, abruptly dilating at or above the midpoint of its length, curved, 25–50 mm long; staminal cup conspicuous, basally pigmented green or yellow, exserted from the throat of the perianth or adnate to the dilated portion of the tube; stigmatic papillae unicellular ..... *Eucharis*

1b. Leaf margins nonundulate; flowers declinate to subpendulous via the curving of the pedicel; perianth funnelform; tube funnelform, dilating gradually from base (rarely subcylindrical), straight or only slightly cernuous, 25 mm or less long; staminal cup inconspicuous and unpigmented, reduced to a membranous, basal

connation of the filaments; stigmatic papillae multicellular ..... *Caliphruria*

Eucharis Planchon et Linden, Linden's Ann. Cat. Hort. 8: 3. 1852; Fl. des Serres Jard. Eur. Ser. 1, 8: 107. 1853. TYPE: *Eucharis candida* Planchon et Linden. *Urceolina* subg. *Eucharis* (Planchon & Linden) Traub, Pl. Life 27: 57–59. 1971.

Evergreen, bulbous geophytes of rain forest understory. Bulb tunicate, usually offsetting vigorously. Leaves petiolate, persistent, glabrous; petiole subterete, somewhat concave adaxially proximal to the sinus, convex abaxially, light green, winged distally by attenuation of the lamina; lamina ovate, elliptic, ovate- or elliptic-lanceolate, usually thin, predominantly hypostomatic, usually lustrous, dark green adaxially, light or silvery green abaxially, smooth or plicate between the parallel veins, cuticle of the abaxial epidermis variably striate, margins frequently undulate, apically acute or acuminate, basally attenuate to the petiole, rarely appearing subcordate. Inflorescence scapose, umbellate (composed of 1 to several reduced helicoid cymes); scape solid, terete or slightly compressed, glaucous, terminating in 2 green or greenish white, ovate-lanceolate, valvate-imbricate, marcescent bracts enclosing the flowers and several secondary bracts before anthesis. Flowers 2–10(–12), pedicellate (rarely subsessile), each subtended by a lanceolate bracteole, pendent or declinate, sometimes fragrant, white, usually protandrous; perianth crateriform or campanulate; tube cylindrical, dilating abruptly above its midpoint, sometimes stained green proximally; limb of 6 tepals in 2 series spreading widely from the throat or imbricate for half their length, the outer series usually longer, narrower and apiculate; the inner series acute, obtuse, or minutely apiculate. Stamens 6, variously connate below, pigmented yellow or green proximally; free filament linear, subulate, or otherwise petaloid; anthers oblong to linear, sub-basifixed or dorsifixed, eventually becoming versatile, introrse, dehiscing longitudinally; pollen grain boat-shaped elliptic, monosulcate, the exine reticulate. Style filiform, included within, equal to, or exserted from the staminal cup; stigma obtusely 3-lobed, papillose. Ovary inferior, green or white, globose-ellipsoid, oblong, occasionally trigonous, 3-locular; septal nectaries present; ovules 2–20 per locule, placentation axile, globose, anatropous. Fruit a 3-lobed, loculicidal capsule, thin-walled or leathery, green or bright orange; seed globose or ellipsoid, sometimes angled by pressure, turgid, with copious endosperm, few per locule; testa thin, phytomelanous, lustrous (rarely dull) black, dark brown or blue, usually smooth. Chromosome numbers: $2n = 46$, 68, 92, 138.

KEY TO THE SUBGENERA OF *EUCHARIS*

1a. Flowers 3–7 cm long, usually pendulous, only rarely and mildly fragrant, crateriform (rarely somewhat campanulate); perianth tube cylindrical below, dilated abruptly just below the throat (rarely in the upper ¼), usually strongly curved, white; limb segments usually spreading widely (ca. 90°) at perianth throat; staminal cup inserted at throat of tube, proximally spotted or stained yellow, green, or yellow-orange equally on the exterior and interior of the cup; distal portion of filament usually widely subulate (> 1.5 mm wide) or otherwise petaloid; anthers ± erect at anthesis; ovules 2–9(–10) per locule; capsule leathery and bright orange (rarely green, in which case tardily dehiscent) ..... *Eucharis* subg. *Eucharis*

1b. Flowers 7–8 cm long, declinate or subpendulous, strongly fragrant, funnelform-campanulate to crateriform; perianth tube cylindrical below, dilated abruptly at ⅓–½ its length, green (at least proximally); limb segments usually imbricate for half their length; staminal cup partially adnate to upper portion of tube, sometimes reduced, flushed (yellow-)green, particularly along the filamental traces, with the pigmentation most intense on the interior of the cup; distal portion of the filament usually narrowly subulate (≤ 1 mm wide); anthers versatile at anthesis; ovules (7, 9–)16–20 per locule ..... *Eucharis* subg. *Heterocharis*

Eucharis subg. **Eucharis**

Leaves glabrous, petiolate, persistent; lamina ovate, elliptic, or lanceolate, mostly thin, margins usually undulate, variably plicate between the parallel veins, apically acute or acuminate, basally attenuate to the petiole or rarely subcordate, mostly dark green and lustrous adaxially, light or silvery green abaxially, the abaxial epidermis variously striate; petiole subterete, somewhat channeled adaxially proximal to the sinus. Inflorescence scapose, umbellate, terminating in 2 greenish white marcescent bracts. Flowers pedicellate, (3–)5–10, only rarely with noticeable fragrance, mostly pendulous, 3–7 cm long, crateriform (rarely slightly campanulate); perianth tube usually strongly curved, cylindrical below, dilated just below the throat or rarely at ⅓ length, white; limb of 6 white, ovate to ovate-lanceolate tepals usually spreading widely from the throat, often recurved above the middle, the outer 3 usually longer, narrower, and apically apiculate, the midvein often faintly yellow in strong light. Stamens connate into a conspicuous

or rarely reduced staminal cup, usually exserted from the rim of the throat; staminal cup apically white, marked green or yellow (rarely yellow-orange) basally, variously toothed, lobed or entire; distal portion of the filaments petaloid and variously shaped; anthers oblong or linear, subdorsifixed or sub-basifixed, ± erect at anthesis, finally becoming versatile; pollen grain 45–60 μm (polar axis), 55–86 μm (longest equatorial axis), the exine coarsely reticulate. Style filiform, white; stigma obtusely trilobed, glandular pubescent. Ovary globose, elliptic or trigonous, green or white; ovules globose to ellipsoid, axile, superposed, 1–12 per locule, most often 2–4. Fruit a loculicidal capsule, orange and leathery when ripe (rarely remaining green); seeds 1–3(–4) per locule, ca. 1 cm long, turgid, ellipsoid (rarely somewhat compressed), with a lustrous black or blue testa.

Distribution. Fourteen species, (Guatemala) Costa Rica to Bolivia, concentrated on the lower slopes of the northeastern Andes and western Amazonas, usually below 1,000 m.

KEY TO THE SPECIES OF *EUCHARIS* SUBG. *EUCHARIS*

1a. Perianth tube 25 mm or more long.
  2a. Flowers (7–)8–10 (or very rarely 5); ovules 3–9 per locule (or very rarely 2).
    3a. Flowers not fragrant; perianth tube (25–)30–35 mm long; outer tepals (20–)25–30(–33) mm long; staminal cup 8–11 mm long to apex of teeth or lobes; ovules (2–)3–5(–7) per locule ..... 1. *E. candida*
    3b. Flowers mildly fragrant; perianth tube 35–45(–50) mm long; outer tepals (28–)32–45(–47) mm long; staminal cup 10–16 mm long to apex of teeth or lobes; ovules (2–4)7–9 per locule.
      4a. Floral fragrance slightly fetid; flowers pendent; staminal cup less than 15 mm long to apex of teeth or lobes, cleft 3–5 mm between each stamen, nonplicate; staminal teeth (if present) much less than half the length of the subulate portion of the filament; style exserted ca. 1 cm beyond the anthers ..... 2. *E. formosa*
      4b. Floral fragrance sweet; flower perpendicular to vertical axis of scape; staminal cup more than 15 mm long to apex of teeth, cleft very shallowly (less than 2 mm) between each stamen, plicate; staminal teeth half the length of the subulate portion of the filament; style exserted less than 0.5 cm beyond the anthers ..... 3. *E. bakeriana*
  2b. Flowers 2–5(–7); ovules 2–3(–5) per locule.
    5a. Leaves nonplicate, somewhat succulent, margins nonundulate, length-to-width ratio usually less than 3; petiole usually shorter than the lamina; plants of central and western Colombia or Central America.
      6a. Leaves slightly glaucous adaxially; abaxial cuticle densely striate; perianth tube 25–33 mm long; staminal cup irregularly toothed, proximally pigmented pale yellow; stamens always constricted distally into a narrow subulate portion; style exserted less than 0.5 cm beyond anthers; ovary not trigonous; plants of Colombia ..... 4. *E. bonplandii*
      6b. Leaves not glaucous; abaxial cuticle largely devoid of striations; perianth tube (25–)33–45 mm long; staminal cup most frequently edentate, proximally pigmented green; stamens often dilating gradually from apex to base; style exserted 0.5–1 cm beyond anthers; ovary often trigonous; plants of Central America ..... 5. *E. bouchei*
    5b. Leaves plicate, thin, margins undulate, lamina length-to-width ratio usually greater than 3; petiole usually equal to or longer than the lamina; plants of western Ecuador, Colombia, or Amazonas.
      7a. Leaves bullate-pustulate in texture, nonlustrous; staminal cup pigmented yellow-orange proximally; stamens deltoid, dilating gradually from apex to base; ovary white; plants of western Ecuador ..... 6. *E. astrophiala*
      7b. Leaves not bullate-pustulate in texture, lustrous; staminal cup pigmented yellow or green; stamens not deltoid, constricted distally into a narrow (less than 2 mm wide) subulate portion; ovary green; plants of western Colombia or Amazonas.
        8a. Perianth funnelform-campanulate, tube dilated distally at approximately ⅓ its length; staminal cup inconspicuous; filaments connate proximally for 3 mm or less; plant of western Colombia ..... 7. *E. caucana*
        8b. Perianth crateriform, tube dilated abruptly just below the throat; staminal cup conspicuous; filaments connate proximally for 8 mm or more; plants of Amazonas.
          9a. Perianth tube curved gradually throughout the proximal half; staminal cup usually bidentate but sometimes obtusely lobed (rarely one to several stamens quadrate); ovary globose-elliptic at anthesis; testa lustrous black ..... 8. *E. ulei*
          9b. Perianth tube usually curved abruptly above the ovary, then more or less straight for the rest of its length; staminal cup usually quadrately lobed, but one or several stamens occasionally toothed; ovary deeply trigonous at anthesis; testa lustrous blue ..... 9. *E. cyaneosperma*
1b. Perianth tube equal to or less than 25 (or very rarely to 30) mm long.
  10a. Staminal cup usually less than 1 cm long to apex of teeth or lobes, but connate portion of filaments always much shorter than free, subulate portion.

11a. Teeth of the staminal cup acutely long-lanceolate, as long as the subulate portion of the filament; ovules 10 per locule, plants of western Colombia ..... 10. *E. lehmannii*

11b. Teeth of the staminal cup (when present) obtuse, much shorter than the subulate portion of the filaments; ovules fewer than 10 per locule; plants of the Peruvian east Andes.

12a. Staminal cup 3.5 mm long (to apex of teeth), obtusely bidentate between each stamen; free filaments club-shaped (appearing elliptic-lanceolate in dried material), 1.8–2 mm wide, ovules 4–6 per locule ..... 11. *E. corynandra*

12b. Staminal cup reduced to a basal connation of the filaments 0.8–1.5 mm long, edentate or obtusely bidentate; free filaments narrowly subulate, ca. 1 mm wide; ovules 6–8 per locule ..... 12. *E. oxyandra*

10b. Staminal cup usually greater than 1 cm long to apex of teeth or lobes, but connate portion of filaments always longer than the free, subulate portion.

13a. Leaves 7–12(–14) cm wide; staminal cup campanulate, gradually dilating distally, plicate along the filamental traces; ovary green; capsule leathery, bright orange, dehiscent; seeds ellipsoid, with a lustrous, smooth black testa ..... 13. *E. plicata*

13b. Leaves 3–6 cm wide; staminal cup funnelform-cylindrical to cylindrical, often abruptly dilated distally at ½–⅔ length, plicate between the filamental traces; ovary whitish; capsule green, thin-walled, often tardily dehiscent; seeds wedge-shaped, with a dull, rugose black testa ..... 14. *E. castelnaeana*

1. Eucharis candida Planchon et Linden, Linden's Ann. Cat. Hort. 8: 3. 1852; Fl. des Serres Jard. Eur. Ser. 1, 8: 107. 1853. TYPE: ex hort. Linden, supposedly imported from Colombia, no other data, *Planchon s.n.* (MPU). *Urceolina candida* (Planch. & Lind.) Traub, Pl. Life 27: 57–59. 1971. Figures 67–69, 70A.

Bulb subglobose, 3–5(–6) cm long, 3–4(–5) cm diam., neck 1–2.5(–4) cm long, 1–2.5 cm wide; tunics brown. Leaves 1–2, petiole (15–)18–30(–35) cm long, ca. 7 mm thick proximally, ca. 3–4 mm thick distally; lamina elliptic, (18–)30–35 cm long, (7–)8.5–11.5(–12) cm wide; acuminate, deeply plicate, dark green but only slightly lustrous adaxially, light green abaxially, abaxial cuticle striate, the margins coarsely undulate. Scape (4–)5–6 dm tall, 8–10 mm diam. proximally, 4–5 mm diam. distally; bracts 25–45(–50) mm long, ca. 5–6 mm wide, ovate-lanceolate. Flowers (7–)8–10, rarely as few as 5, without noticeable fragrance; pedicels (9–)15–20(–35) mm long; tube (25–)30–35 mm long, ca. 2 mm diam. for most of its length, abruptly dilated to (7–)10(–11.5) mm at the throat; limb spreading to 4.5–6 cm wide; tepals sometimes recurved distally, outer tepals (20–)25–30(–33) mm long, (9–)10.5–14(–15) mm wide, ovate-lanceolate, apiculate, the apiculum only slightly or obscurely tufted adaxially; inner series (20–)22–28(–32) mm long, (10–)12–15(–20) mm wide, ovate, acute to minutely apiculate. Staminal cup funnelform-cylindrical to slightly campanulate, rarely widely ampliate distally, (7–)8–11 mm long (to apex of teeth or lobes), (10–)13–16(–18) mm wide, most frequently edentate and lobed between each stamen, at times bidentate or irregularly toothed, widely spotted green to greenish yellow below each stamen; teeth, when present, 1–2 mm long, < 1 mm wide, acute or obtuse; cup cleft for (2.5–)3–5(–6) mm between each stamen; stamens (3.5–)4.5–5.5(–6) mm wide proximally; distal subulate portion (3.5–)4.5–6(–6.5) mm long, 1.5–2 mm wide at the base; anthers (3.5–)4–5(–6) mm long, oblong; pollen grain 46.8–50 μm polar diam., 68.7–73 μm longest equatorial diam. Style (38–)45–55 mm long, exserted 0.5–1 cm beyond the anthers; stigma 2—d3 mm wide. Ovary globose-ellipsoid, green, 5–7(–8) mm long, 4–6(–7) mm diam.; ovules (2–)3–5(–7) per locule. Capsule (1.5–)1.8–2.4 cm long, (2–)2.5–2.9 cm wide, bright orange, leathery; pedicel 2–4 cm long; seeds 1–2(–3) per locule, ellipsoid, ca. 1 cm long, ca. 0.5 cm diam., with a lustrous, smooth black testa. Chromosome number: $2n = 46$.

Distribution. Understory of primary rain forest chiefly in the Oriente of Ecuador, particularly the Río Napo valley, occasional in north Peru and southeast Colombia (Figs. 71, 72) at (100–180)240–550(1,000–1,600) m. Flowering at any time of the year, most frequently in February, March, and August.

Vernacular name. Cebolleta.

Additional specimens examined. COLOMBIA. AMAZONAS: Puerto Nariño, 24 Jul 1965, *Lozano et al. 594* (COL); Trapecio amazonica, Loretoyacu River, ca. 100 m, Oct. 1946, *Schultes & Black 8478* (US). Eucharis candida was originally described from cultivated material supposedly originating from Colombia, a country in which it has been encountered only rarely. The species previously has been delimited by the absence of staminal dentation; however, this character varies considerably throughout the range of *E. candida* (Fig. 70A), as in the related species *E. formosa* and *E. ulei*. Peruvian populations of *E. candida* are variable in the shape of the staminal cup (Figs. 68, 69), even among flowers of the same inflorescence.

Eucharis candida is most common throughout the upper Napo Valley in eastern Ecuador and is very often sympatric with the larger-flowered and more widely distributed *E. formosa* (Figs. 71, 72). In one instance, two specimens (*Harling & Andersson 11719*), one each of the two species, were collected under the same number. To date, no species of *Eucharis* other than these two have been collected north of the Pastaza valley in eastern Ecuador. On the basis of herbarium study alone, Ecuadorean populations of these two taxa form a mosaic that seemed taxonomically insoluble until living material of both species from several populations was collected and flowered. Phenetic and karyotype analyses (Meerow, in press) support their recognition as distinct species and suggest that *E. candida* and *E. formosa* have hybridized in at least one area of sympatry.

Eucharis candida may be separated from *E. formosa* by its smaller leaves and flowers, complete absence of fragrance (*E. formosa* produces a mild, "sour" odor), and generally fewer ovules per locule (though both species are variable in ovule number). On the basis of known collections, *Eucharis formosa* is slightly better represented in the Pastaza valley than *E. candida*.

2. Eucharis formosa Meerow, Sida 21: 29–49. 1987. TYPE: Ecuador. Morona-Santiago: Road Limón–Macas, ca. km 20 from Limón, primary rain forest and rastrojos, 700–900 m, 26 Mar. 1974, *Harling & Andersson 12915* (holotype, GB; isotype, FLAS). Figures 67, 70B, 73–78.

Bulb subglobose, 4–7 cm long, 3–5 cm diam., neck 2–5 cm long, ca. 1 cm thick, tunics brown. Leaves 1–2(–3); petiole 25–38(–42) cm long, 8.5–1 mm thick proximally, 5–6 mm thick distally; lamina elliptic, (21–)30–45(–52) cm long, (8–)11–15(–16) cm wide, usually conspicuously plicate, dark green and only slightly lustrous adaxially, light green abaxially, abaxial cuticle striate, margins coarsely undulate. Scape (5–)6–7(–8) dm tall, ca. 1 cm diam. proximally, 5–6 mm diam. distally; bracts ovate-lanceolate, (36–)43–60(–85) mm long, 10–15 cm wide at the base. Flowers 8–10, very rarely fewer, pendent, emitting a mild "sour" odor; pedicels (8–)12–18(–30) mm long; tube 35–45 (–50) mm long, ca. 2–2.5 mm wide for most of its length, abruptly dilated to (9–)10–13(–14) mm at the throat; limb spreading to (55–)60–70(–80) cm; tepals sometimes recurved distally; outer tepals narrowly ovate, (30–)35–45(–47) mm long, (10–)15–18(–20) mm wide, apiculate, apiculum conspicuously horned adaxially (Ecuadorean populations); inner tepals ovate, (28–)31–40(–45) mm long, (15–)18–22(–25) mm wide, acute to minutely apiculate. Staminal cup funnelform-cylindrical, 10–13(–15) mm long (to apex of teeth or lobes), (15–)17–20(–22) mm wide; flushed greenish yellow proximally, with the greatest concentration of pigment below each free filament, rarely only widely punctate; bidentate, irregularly toothed, lobed or quadrate between the distal portion of the filament; cup cleft between each stamen for 3–5 mm; teeth when present acute or obtuse, ≤ 2 mm long; each stamen (5–)6–7(–7.5) mm wide tooth to tooth or lobe to lobe; distal portion of filament subulate, (4.5–)5–6.6(–7) mm long, (1.8–)2–2.5 (–3) mm wide at point of dilation; anthers oblong,

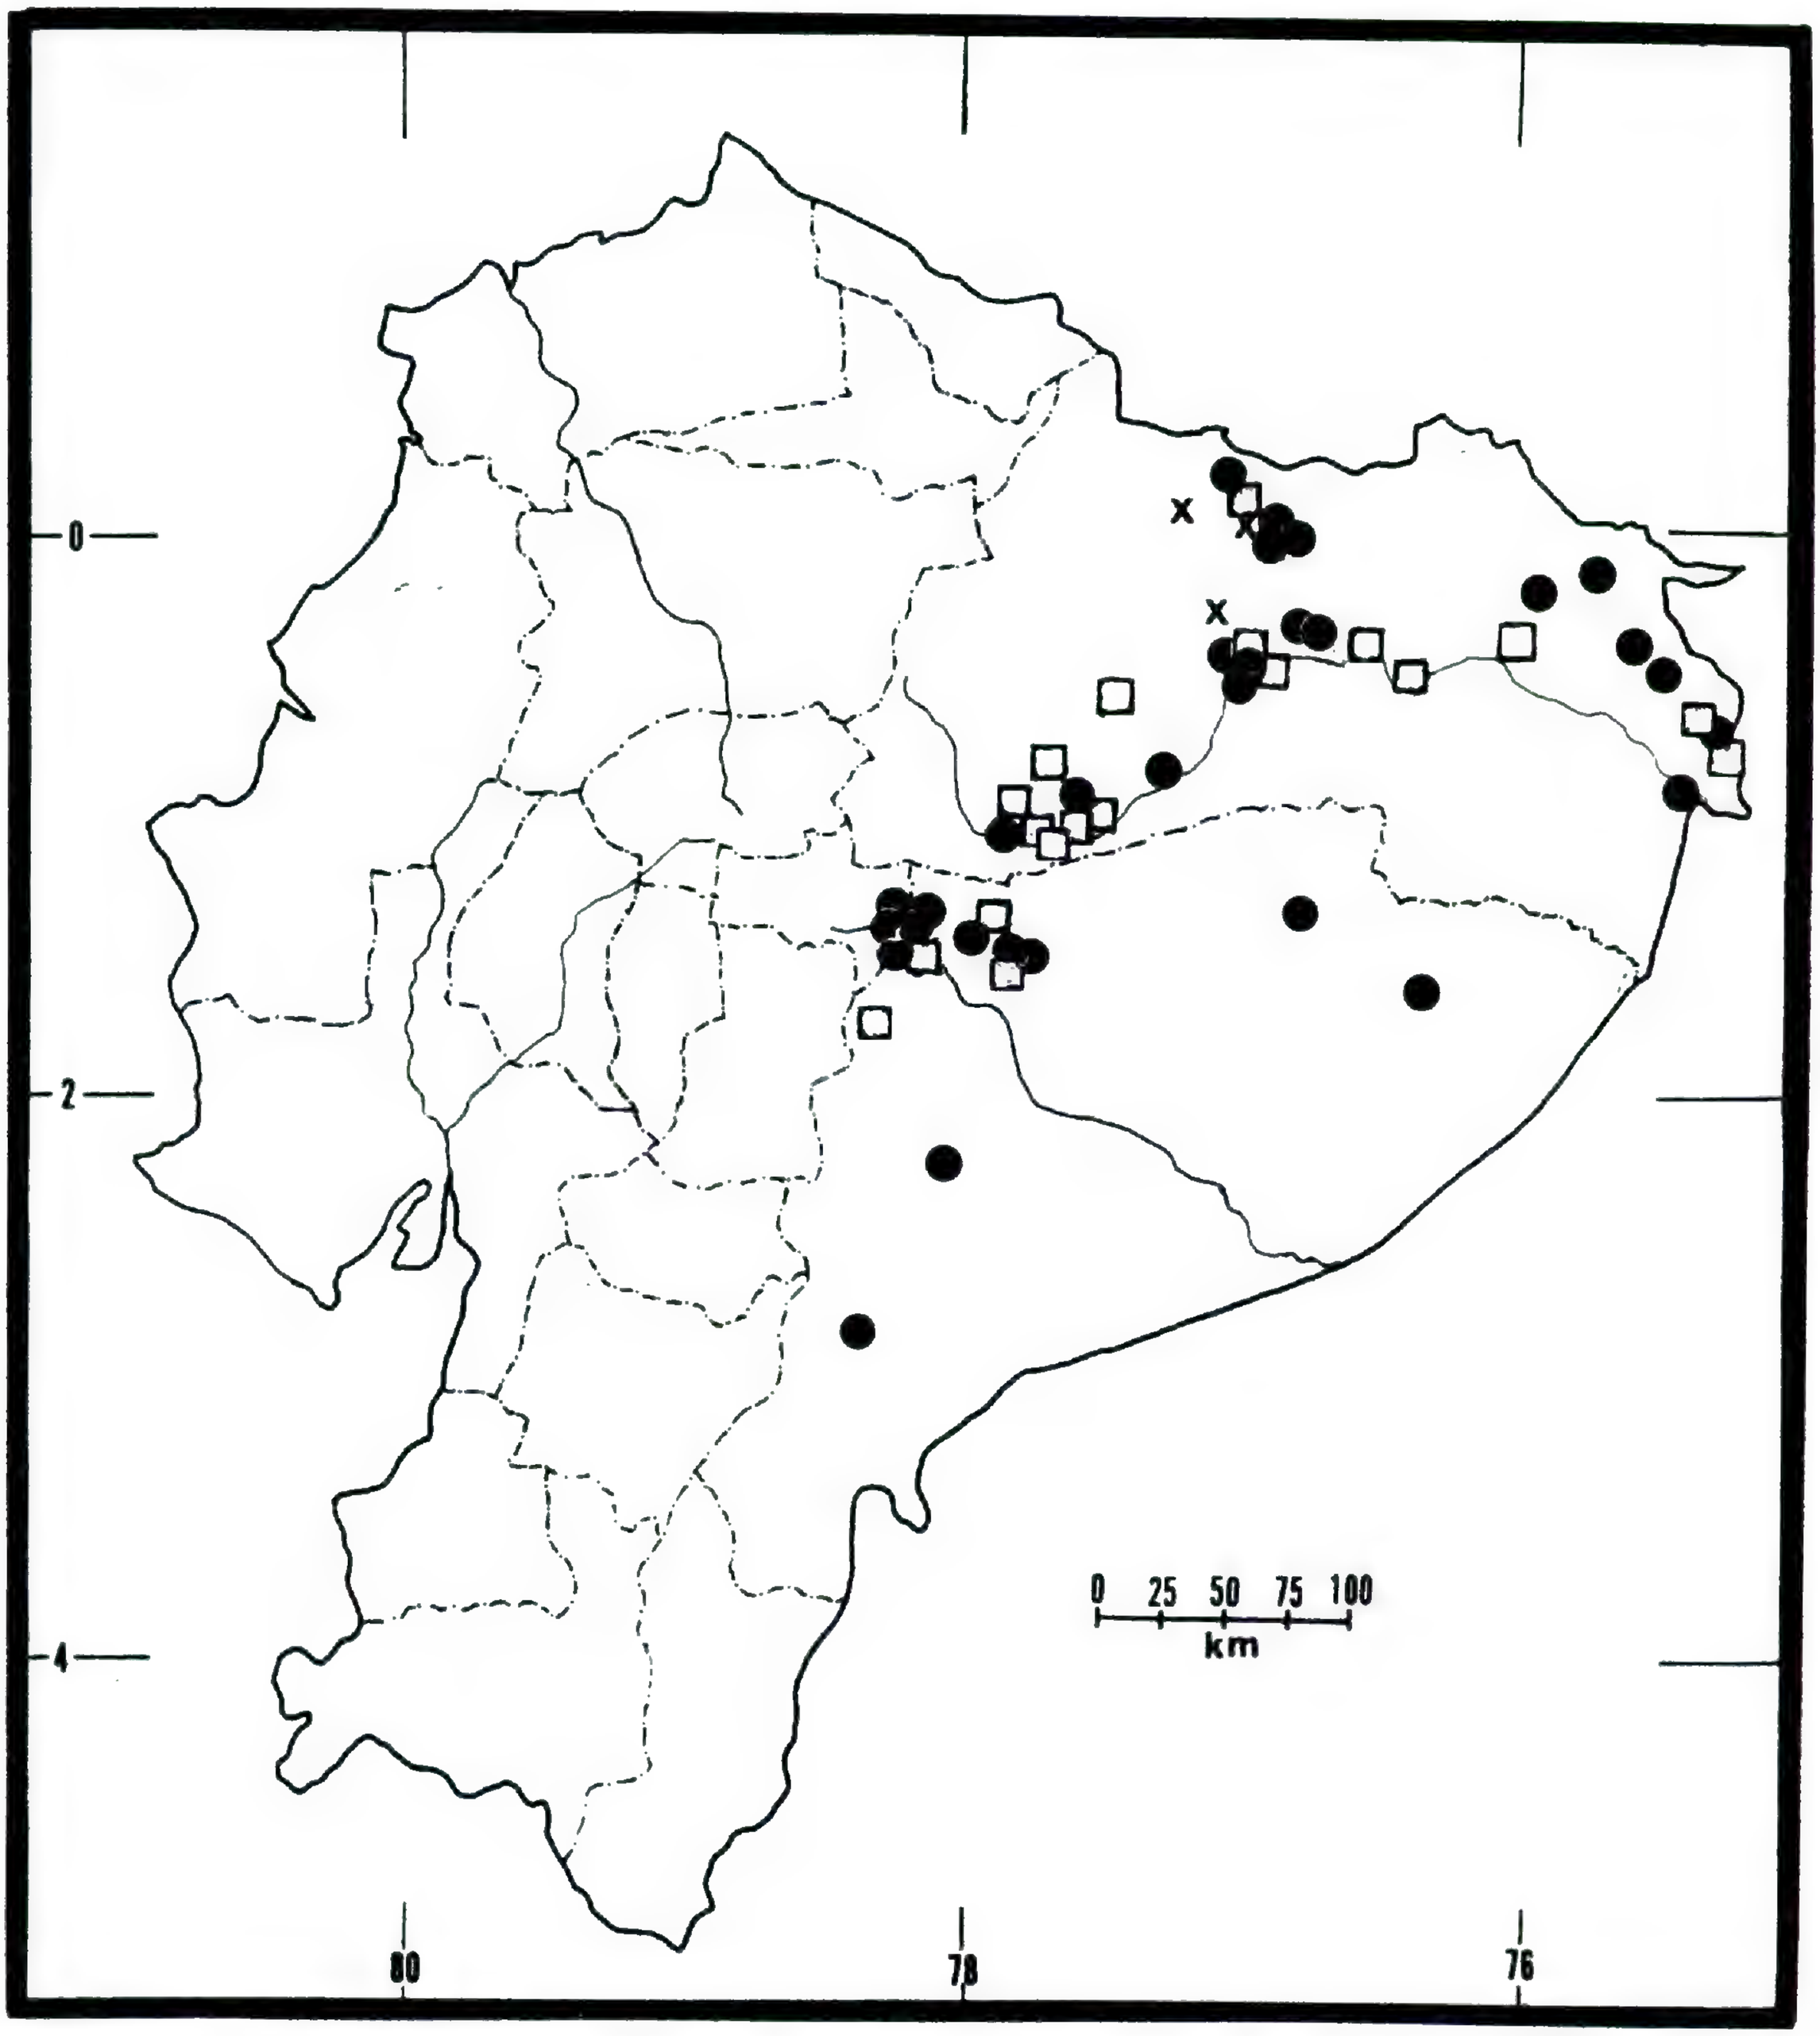

FIGURE 71. Distributions of *Eucharis candida* (squares) and *E. formosa* (circles) in Ecuador. X = *E. candida* × *E. formosa*.

4.5–5.5(–6) mm long, gray-brown; pollen grain 47.7–53.4 μm polar diam., 65.5–73.8 μm longest equatorial diam. Style 5.5–6(–6.5) cm long, exserted ca. 1 cm beyond the anthers; stigma ca. 2–3 mm wide. Ovary globose-ellipsoid, 6–8.5(–10) mm long, (4.5–)5.5–7(–7.5) mm diam., green; ovules (2–)5–7(–8). Capsule 1.5–2 cm long, 2–3 cm wide, bright orange, leathery; pedicels 3–4 cm long; seeds (1–)2–4 per locule, ellipsoid, 8–10 mm long, 5–6 mm diam., with a lustrous, smooth black testa. Chromosome number: $2n = 46$.

Distribution. Rich, moist soil in the understory of premontane and lower montane rain forest, chiefly in the Napo and Pastaza drainage of Ecuador (Fig. 71); less frequent in Amazonian Peru and Colombia, the lower "ceja de la selva" of north-central Peru, and upper Huallaga valley of Peru (Fig. 72); rare in central Colombia (a single, poorly documented, and very disjunct collection (*Killip s.n.*, COL) from near Popayan may be of cultivated origin), 100–1,800 m. Flowering most commonly January–March.

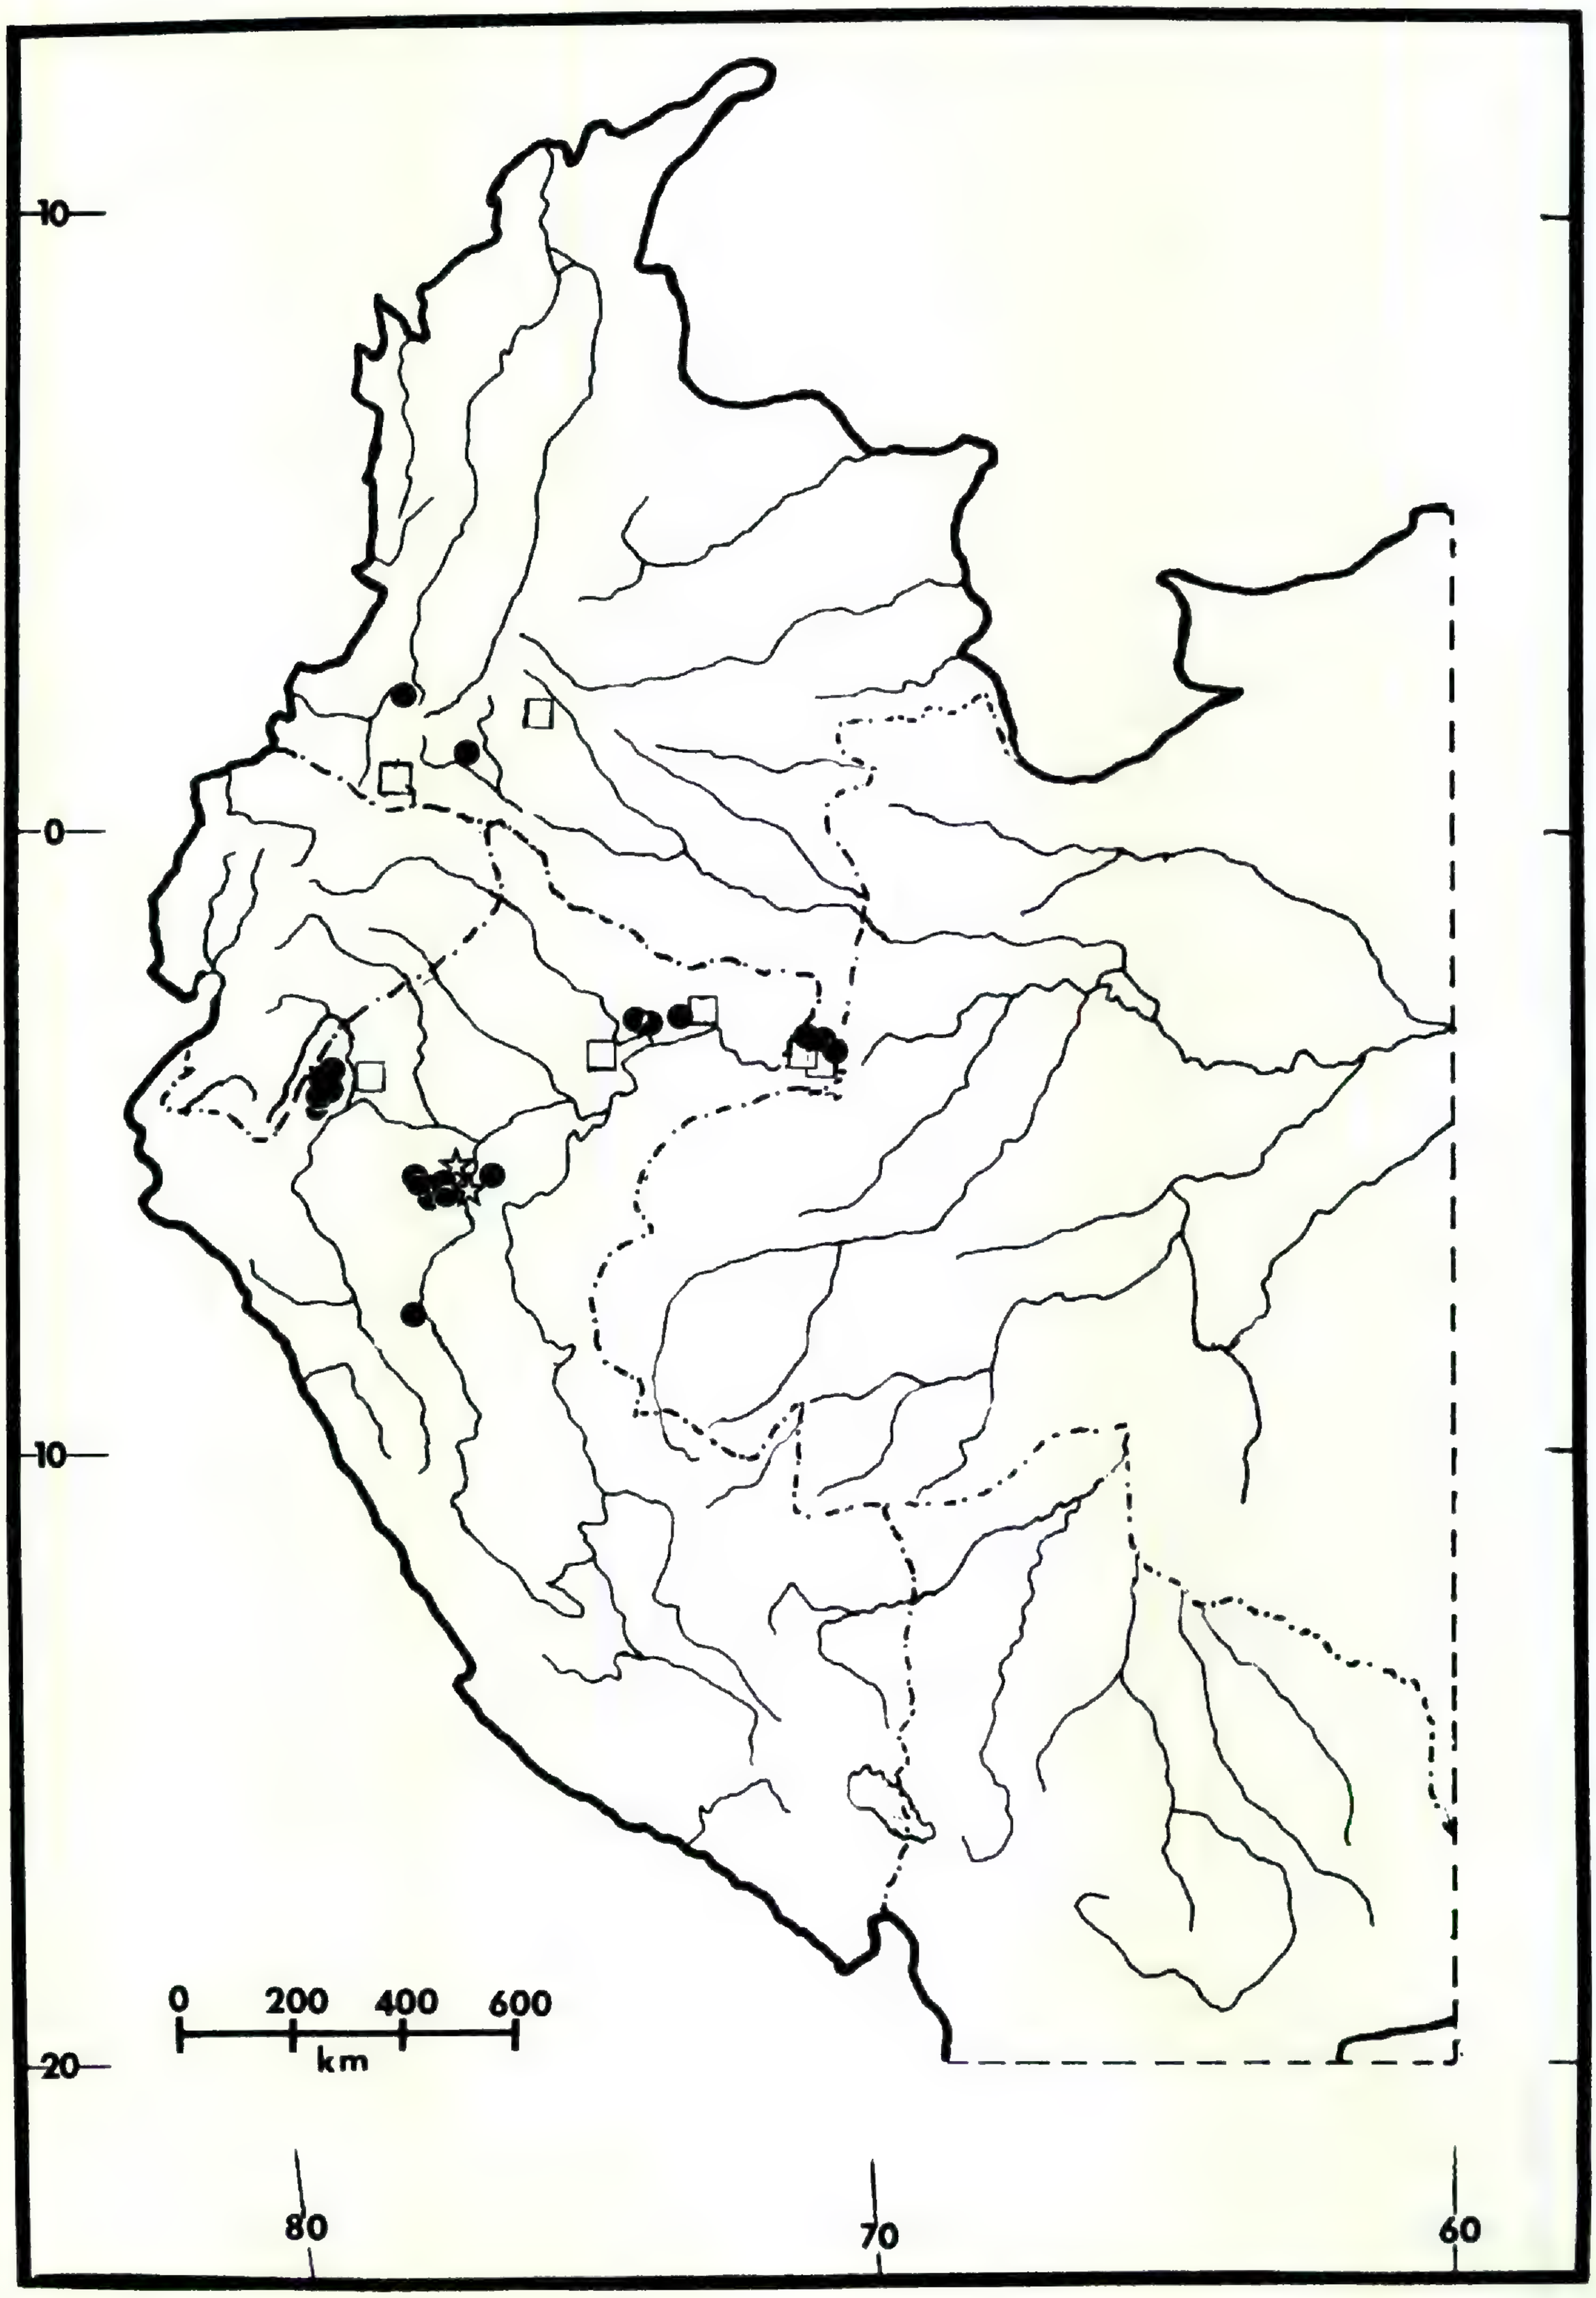

FIGURE 72. Distributions of *Eucharis bakeriana* (stars), *E. candida* (squares), and *E. formosa* (circles) in northwestern-central South America exclusive of Ecuador.

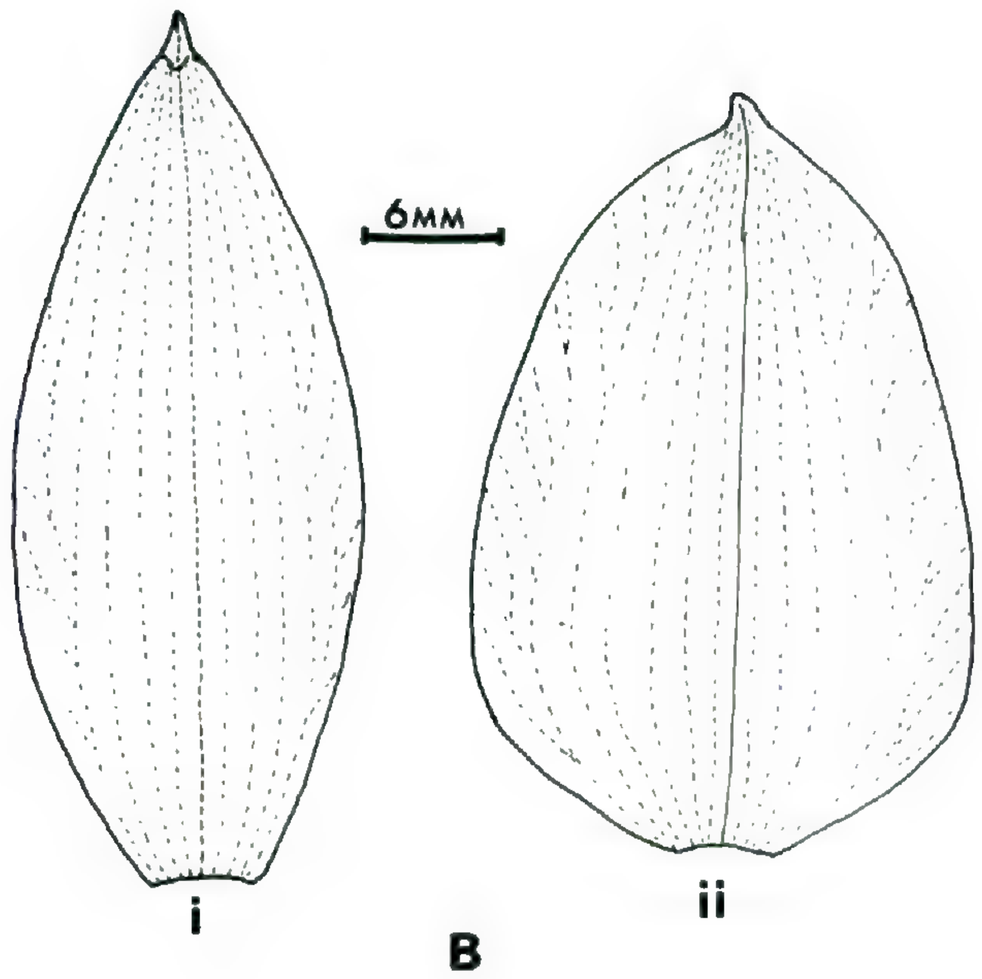
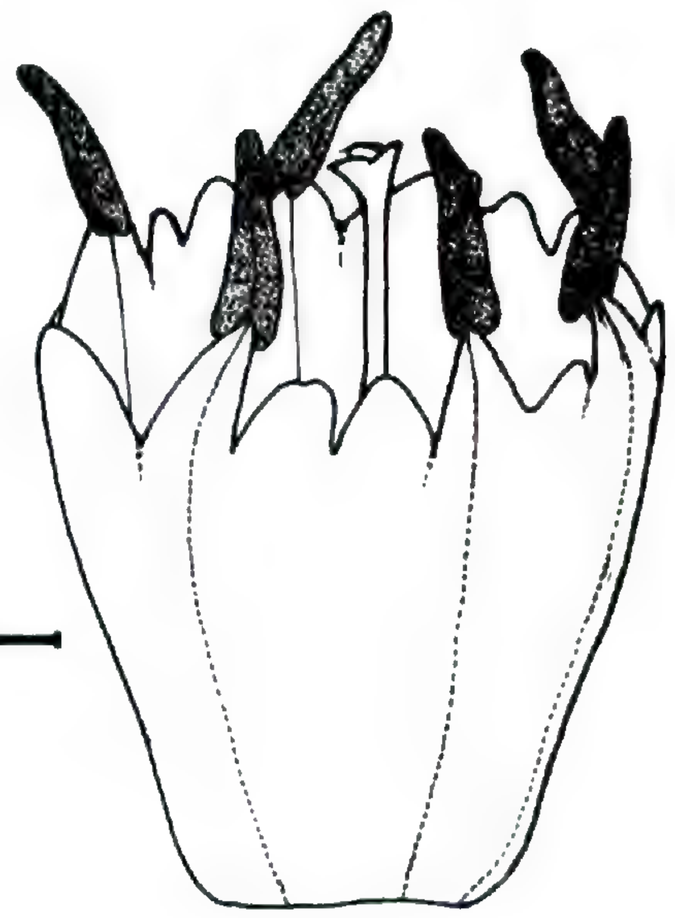
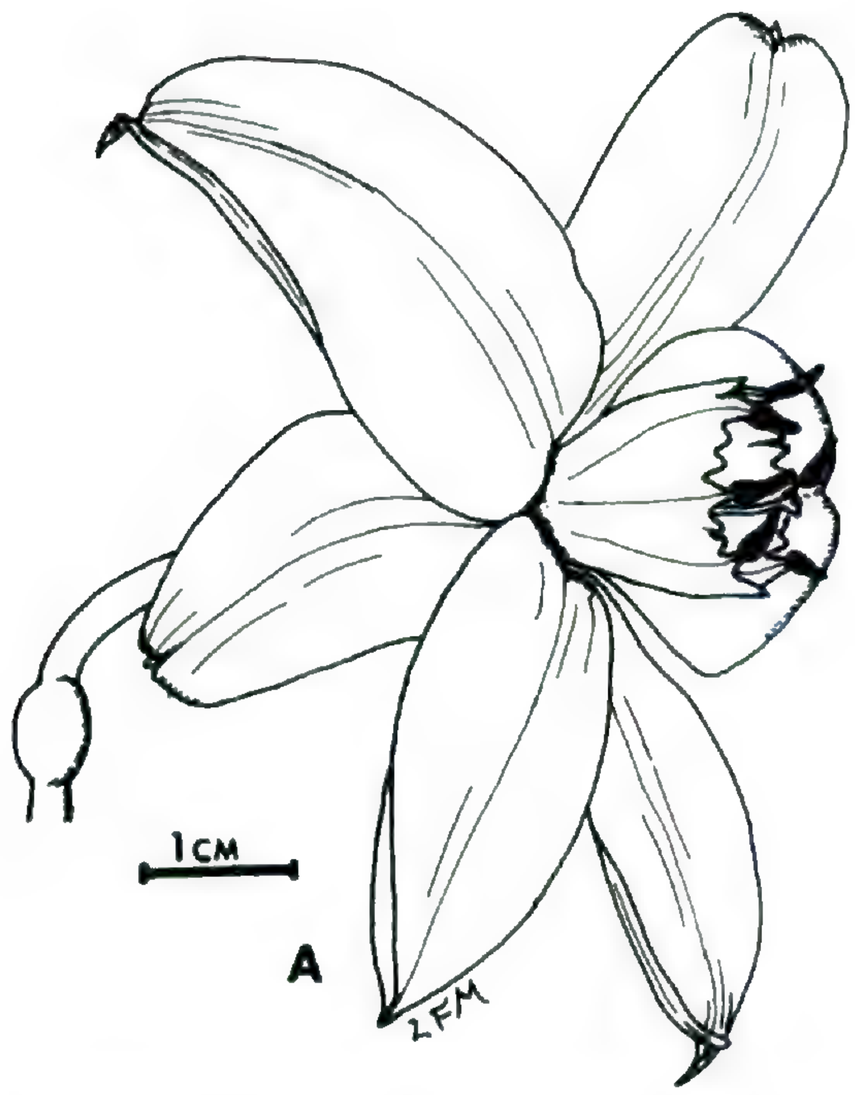
Eucharis formosa is the most commonly encountered species in eastern Ecuador (Fig. 71). It extends into Amazonian Peru and Colombia and occurs in the lower "ceja de la selva" forests of north-central Peru (Fig. 72). Like the closely related *E. candida*, *E. formosa* has a wide elevational range, possibly in part from cultivation (Meerow, 1987e). The flowers emit a mild and unpleasant "sour" odor. *Eucharis formosa* is larger in all parts than *E. candida* and generally has more ovules per locule. The conspicuous horn on the apiculum of the outer tepal is characteristic of Ecuadorean populations of *E. formosa* (Fig. 67Ai); this character is not obvious in Peruvian collections. Forms with toothed or edentate staminal cups occur throughout the range of this species without any observable geographic pattern (Fig. 70B). Flowers of the same inflorescence can vary for this character. A Peruvian collection (*Schunke 14174*) shows some karyotypic and allozyme divergence from Ecuadorean populations (Meerow, in press). In floral morphology (Fig. 78), however, it is indistinguishable from other Ecuadorean material. A second collection (*Schunke 14171*), from the same general vicinity of Peru as *Schunke 14174*, has only shallowly plicate leaves and reduced pigmentation of the staminal cup (Figs. 76, 77). At present, too little is known about *E. formosa* in Peru to justify recognition of subspecific taxa.

3. Eucharis bakeriana N. E. Brown, Gard. Chron. 7: 416, fig. 61. 1890. TYPE: Colombia (?): no other data, ex hort. Sander and Co., 1890, *s.n.*, in part (holotype, K). *Urceolina bakeriana* (N. E. Brown) Traub, Pl. Life 27: 57–59. 1971. Figure 79.

Bulb to ca. 5 cm diam., the tunics brown. Leaves 2–4; petiole 15–17, 25–30 cm long, (5–)10–11 mm wide; lamina elliptic, 24–29.5, 44–55 cm long, (10–)17–20 cm wide, somewhat succulent, smooth. Scape 6–8 dm tall, ca. 1 cm diam. proximally, 5–7 mm diam. distally; bracts ovate-lanceolate, 30–38 mm long, ca. 10 mm wide at the base. Flowers (5–)10, with a mild, sweet fragrance, pedicels 10–30 mm long; tube 35–40 mm long,







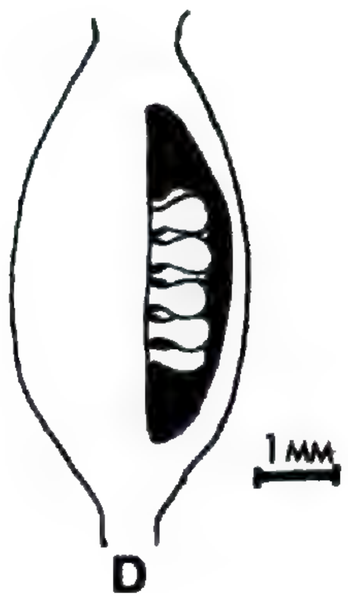


FIGURE 79. *Eucharis bakeriana* (*Meerow 1108*, FLAS).—A. flower.—B. Tepals. i. Outer tepal. ii. Inner tepal.—C. Staminal cup.—D. Ovary, longitudinal section.

2–3 mm wide for most of its length, abruptly dilated near the throat to 9–9.7 mm wide, curved abruptly just above the ovary and straight for the rest of its length, thus perpendicular to the vertical axis of the scape; limb spreading to 50–60 mm wide; outer tepals 28.5–32 mm long, ca. (10–)16.8 mm wide, ovate-lanceolate to ovate, apiculate; inner tepals 26–30 mm long, (14–)20–22 mm wide, ovate, acute to minutely apiculate. Staminal cup subcylindrical to campanulate, ca. 16 mm long (to apex of teeth), 13–15 mm wide, slightly plicate between the filamental trace, very shallowly cleft between each stamen (< 1 mm), proximally marked green, obtusely bidentate between each free filament; teeth 2–3 mm long, half the length of the subulate portion of the free filament; each stamen 5–6.4 mm wide tooth to tooth; subulate portion of the filament 3–4.5 mm long, 1.5–1.7 mm wide; anthers oblong, 5.4–6 mm long; pollen grain ca. 50.7 μm polar diam., ca. 76.9 μm longest equatorial diam. Style 45–54.5 mm long, exserted just slightly past the anthers; stigma 2.4–2.8 mm wide. Ovary ellipsoid, 6.5–7 mm long, 5.3–6.5 mm diam.; ovules 2–3, 8–9 per locule. Capsule ca. 1.5–2 cm long, 2.5–3 cm wide, bright orange, leathery; seeds ellipsoid, ca. 1 cm long, 0.5 cm diam., with a lustrous, smooth black testa. Chromosome number: $2n = 46$.

Distribution. Very rare in the understory of lower montane rain forest in the middle Río Huallaga valley of Peru, 800 m (Fig. 72). Living material

from which the type specimen was prepared was reportedly collected in Colombia, but I have seen no Colombian material. Flowering season not known.

Additional specimens examined. PERU. SAN MARTÍN: 17 km NE of Tarapoto on road to Yurimaguas, trail along stream to waterfall, wet premontane forest on rocky hills, 6°30′S, 76°20′W, 800 m, 21 July 1982 (fr), *Gentry et al. 37852* (MO); vicinity of Tarapoto, no other data, flowered in cultivation from material collected by L. Besse, *Meerow 1108* (FLAS).

The type of *E. bakeriana* was prepared from living material supposedly collected in Colombia. When I examined the type specimen, only the several large flowers present in the fragment packet resembled the figure that accompanied Brown's (1890) description of *E. bakeriana*. The mounted material was referable to the smaller-flowered *E. candida*. At the time, I thought that *E. bakeriana* might represent an aberrant form of *E. candida*. Several years later I received a bulb of a *Eucharis* collected near Tarapoto, Peru, by Libby Besse of SEL. The flowers that grew from the bulb bore an exact resemblance in habit and staminal cup morphology to *E. bakeriana*, though with considerably more ovules per locule. At present, *E. bakeriana* is known only from the type, the Besse material, and a fruiting specimen referred to this species on the basis of leaf size.

Eucharis bakeriana is distinct from *E. formosa*, its closest phenetic relative, by its nonpendent flowers that are perpendicular to the vertical axis of the scape, very shallowly cleft staminal cup (< 1 mm, vs. 2 mm in *E. formosa*), short subulate portion of the stamen, and sweet floral fragrance (slightly fetid in *E. formosa*). In leaf size and karyotype, *E. bakeriana* is very similar to Peruvian material of *E. formosa* (*Schunke 14174*) but differs by its greater number of subtelocentric chromosomes and the submetacentric morphology of the second-largest pair (Meerow, 1987b). The leaves are only shallowly, if at all, plicate and are thicker.

FIGURE 80. *Eucharis bonplandii* (*Meerow 1098*, FLAS).

4. Eucharis bonplandii (Kunth) Traub, Pl. Life 7: 40. 1951. *Hymenocallis bonplandii* Kunth, Enum. Pl. 5: 666. 1850. TYPE: Colombia. Cundinamarca: Río Magdalena, near Nares, *Bonpland 1657* (holotype, P, photo of type, NY). *Caliphruria bonplandii* (Kunth) Baillon, Bull. Mens. Soc. Linn. Paris 143: 1136. 1894. *Urceolina bonplandii* (Kunth) Traub, Pl. Life 27: 57–59. 1971. Figure 80.

Bulb subglobose, 41–46 mm long, 29–32 mm wide, neck ca. 18 mm long and wide, tunics brown. Leaves 2, somewhat succulent; petiole 8–14(–18) cm long, 6–8 mm thick proximally, 3–4 mm distally, always shorter than the lamina; lamina elliptic, (16–)18–24(–26) cm long, 8.5–11.5 cm wide, bluish green, especially in strong light, slightly glaucous adaxially; lighter green abaxially, the abaxial cuticle densely striate; apex acute to shortly acuminate; attenuate at the base. Scape 4.5–5.8 dm tall, 6–8 mm diam. proximally, 3–4 mm diam. distally; bracts (25–)33–40 mm long, ovate-lanceolate, greenish white. Flowers 5–7, nonfragrant, pendent; pedicels 18–25 mm long; tube 25–33 mm long, 1.8–2.5 mm wide for most of its length, abruptly dilated at the throat to 7–9(–10) mm wide; limb spreading to 47–55 mm wide; outer tepals ovate-lanceolate, 25.7–30.5 mm long, 8–10 mm wide, apiculate; inner tepals 23–28 mm long, 11.5–14 mm wide, acute to minutely apiculate. Staminal cup subcylindrical, (11.5–)12.5–14.3 mm long (to apex of teeth), 11.5–13 mm wide, stained pale yellow proximally, irregularly bidentate between each free filament, one stamen occasionally only lobed or quadrate, cleft 2.6–4 mm between each stamen; teeth variously acute or obtuse, 1–2 mm long; each stamen 3.6–4.5 mm wide tooth to tooth; free portion narrowly subulate, (3.8–)4.5–5.8 mm long, ca. 1.8 mm wide; anthers 4–4.8 mm long, oblong, grayish-brown; pollen grain ca. 43.5 μm polar diam., ca. 63 μm longest equatorial diam. Style 50–60 mm long, exserted just beyond the

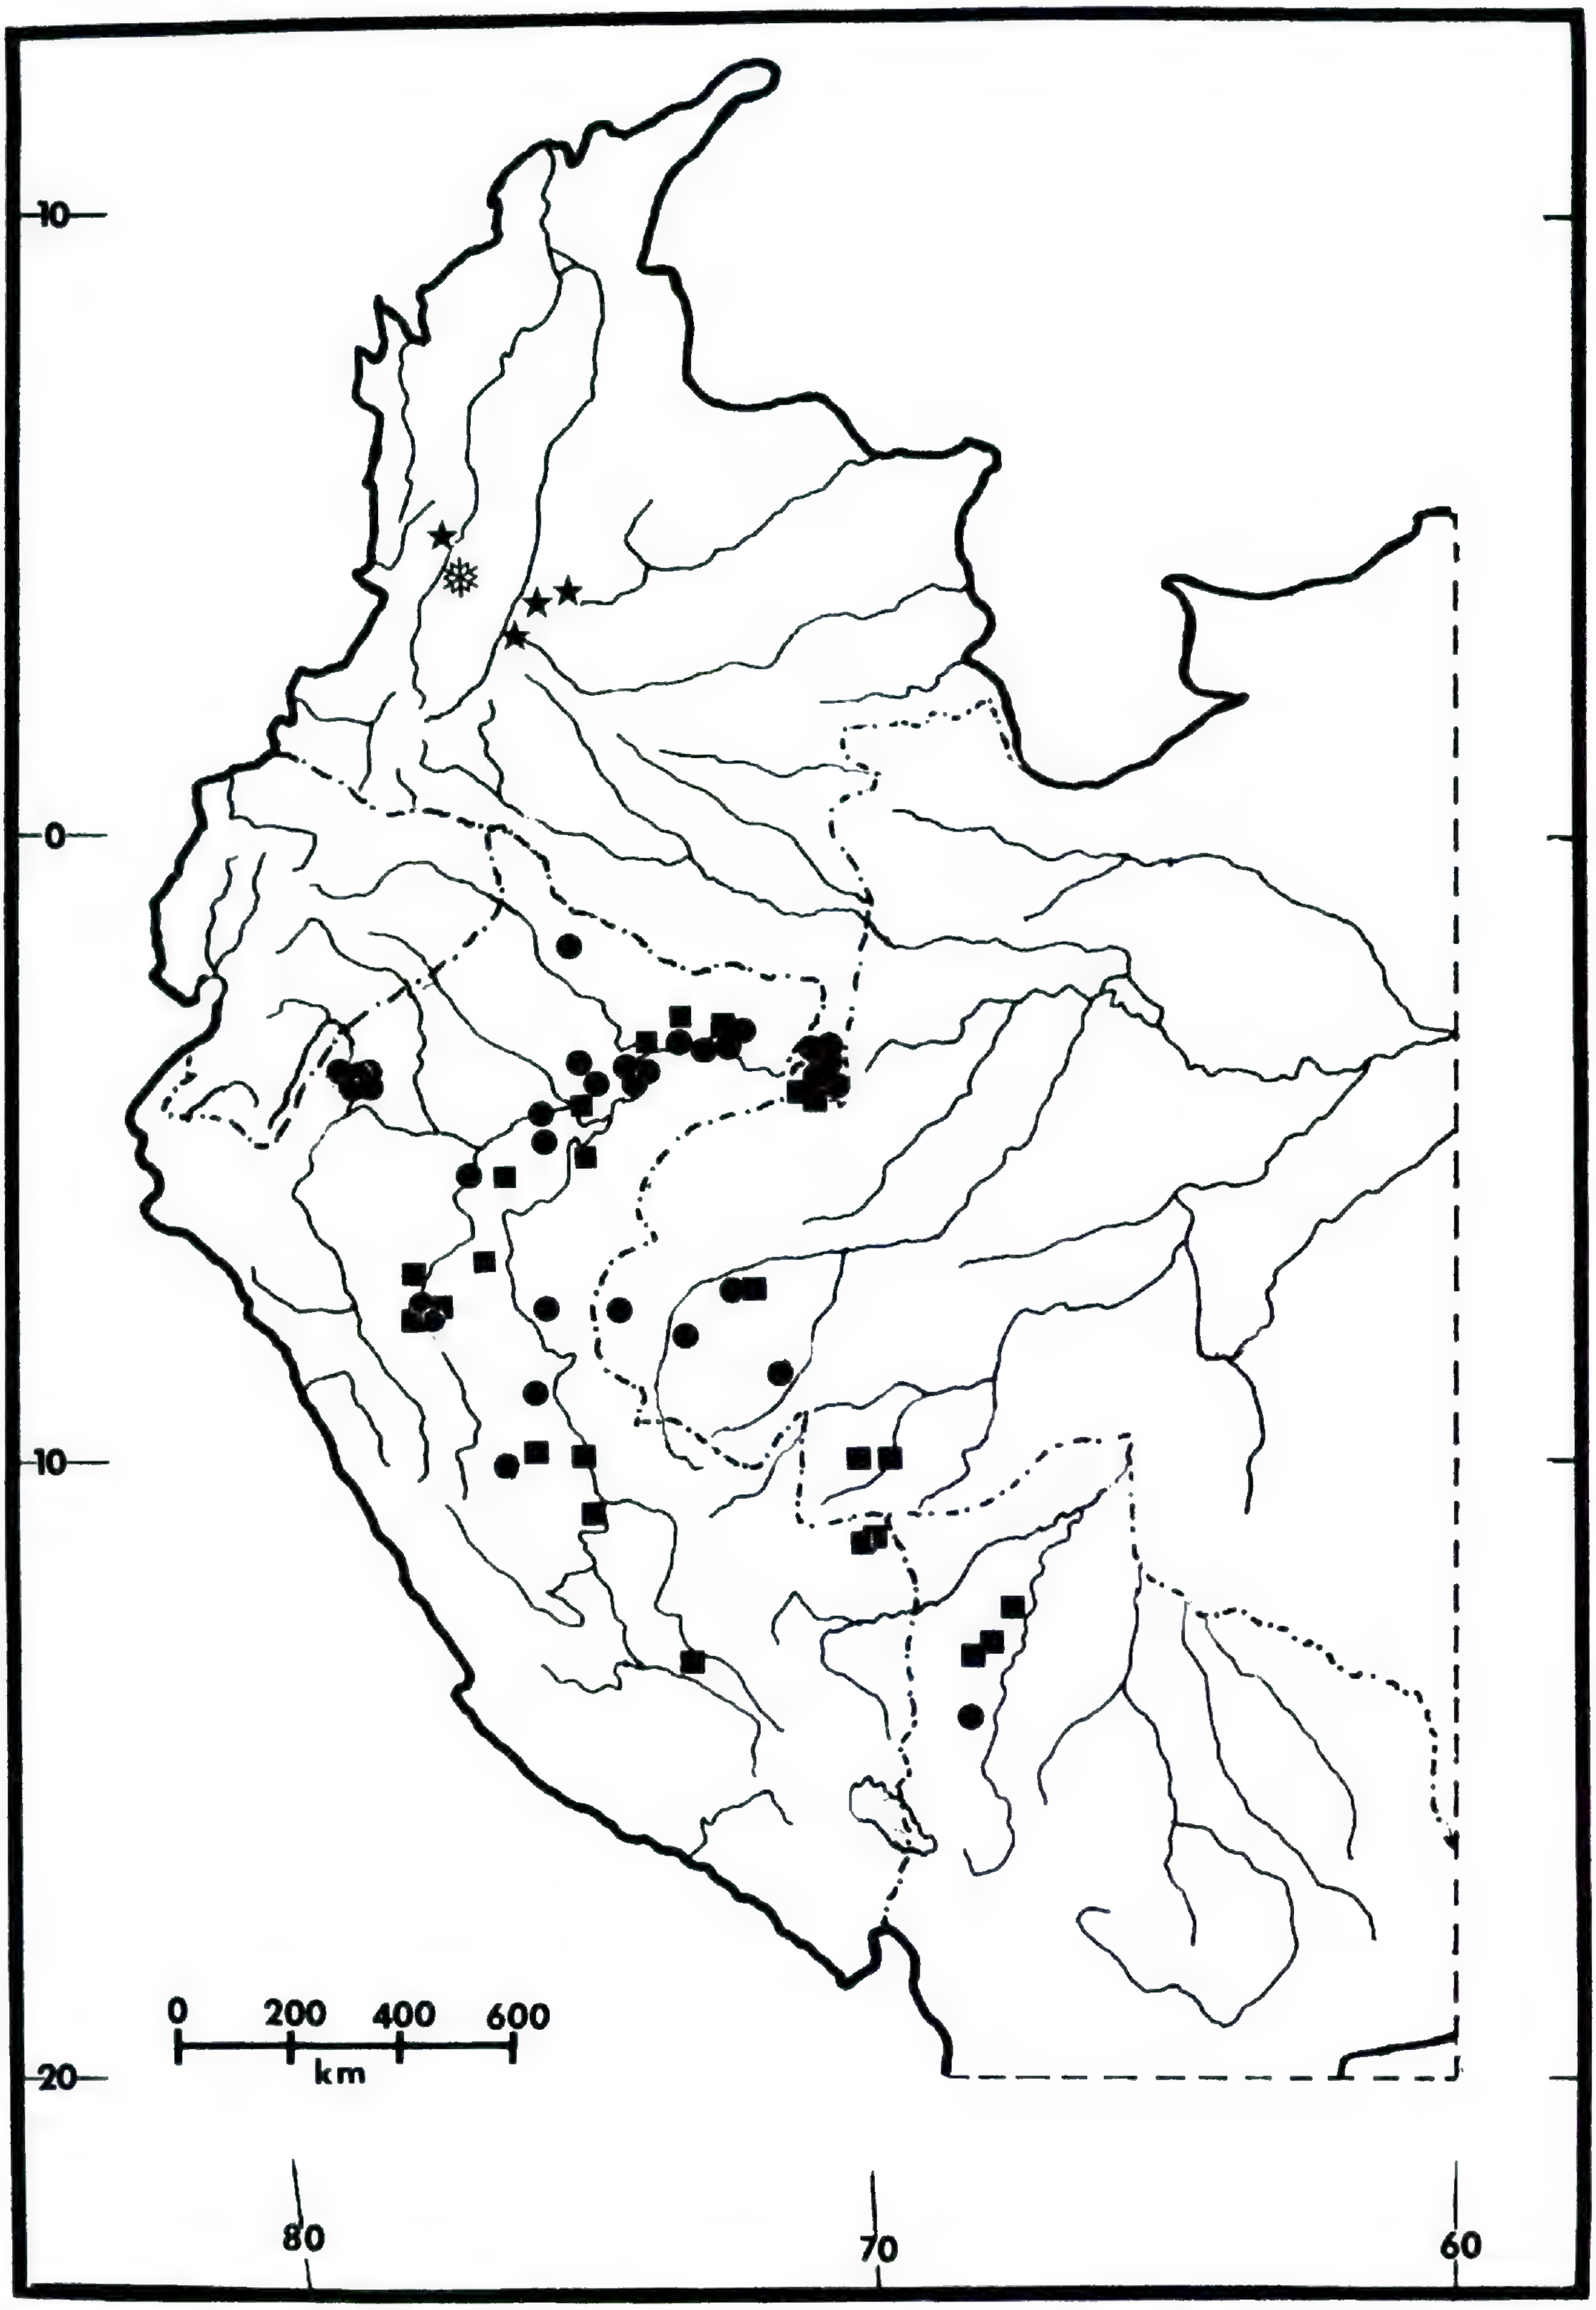

FIGURE 81. Distributions of *Eucharis bonplandii* (stars), *E. caucana* (snowflake), *E. cyaneosperma* (squares) and *E. ulei* (circles) in northwestern-central South America.

anthers; stigma 2–2.7 mm wide. Ovary subglobose, ca. 5–6 mm diam.; ovules 2–3 per locule. Capsule ca. 1 cm long, 2 cm wide, bright orange, leathery; seeds 1–2 per locule, ellipsoid, ca. 1 cm long, ca. 0.5 mm diam., with a lustrous black testa. Chromosome number: $2n = 92$.

Distribution. Rare in central and western Colombia (Fig. 81), in the understory of lower montane rain forest, 400–600(–1,300 m). Flowering February–March, May–June, August.

Additonal specimens examined. COLOMBIA. Department unknown: La Mejita (?), June 1844, *Goudot s.n.* (K, P). CALDAS: Cauca Valley, Tabeja, west of Armenia, 1,100–1,300 m, 23 July 1922, *Pennell et al. 8604* (GH, NY, US). CUNDINAMARCA: Viotá, Quebrada Cachinibulo, 550 m, 18 Feb. 1876, *Andre 1583* (K); same locality as preceding, 600 m, 19 Feb. 1876, *Andre 1721* (K); ex hort. originally collected by J. Paxton near Bogotá, ca. 650 m, received from Foster Gardens, Hawaii, 14 May 1982, *Meerow 1098* (FLAS). TOLIMA: valle del Alto Magdalena, vereda La Chamba (municipio del Guamo), 400 m, 3 Mar. 1963 (fr), *Uribe 4218* (COL).

Eucharis bonplandii is one of only two tetraploid ($2n = 92$) species so far known in the genus. The species is known only from Colombia, and has been rarely collected. Among Amazonian species, *E. bonplandii* has the greatest phenetic relationship to *E. ulei*, with five similarly sized flowers and two ovules per locule in common. It may be separated from *E. ulei* by having succulent, glaucous leaves and short petioles. The staminal cup of *E. bonplandii* is pigmented pale yellow at its base; that of *E. ulei* is marked green. *Eucharis bonplandii* and *E. bouchei* are the northernmost species of subg. *Eucharis*, and thus may form a monophyletic, tetraploid group (Meerow, 1987d). Both species have relatively short petioles. From *E. bouchei*, *E. bonplandii* differs primarily by its leaf glaucousness and longer pedicels.

5. Eucharis bouchei Woodson & Allen, Ann. Missouri Bot. Gard. 24: 181. 1937. *Urceolina bouchei* (Woodson & Allen) Traub, Pl. Life 27: 57–59. 1971. TYPE: Panama. Coclé: El Valle de Antón, 500–700 m, 23–27 July 1935, *Seibert 466* (holotype, MO). Figure 82.

Bulb subglobose, 30–45(–85) mm long, (25–)30–40(–50) mm diam.; neck short, to 25 mm long, 10–20 mm wide; tunics brown. Leaves 1–3(–4); petiole (9–)15–25(–28) cm long, 7–8 mm wide proximally, 5–6 mm wide distally; lamina widely (ovate-)elliptic, (17–)20–25(–40) cm long, (7–)8–10(–14) cm wide, shortly acuminate, slightly succulent, lustrous bright green adaxially, dull pale green abaxially, smooth, margins mostly nonundulate; abaxial cuticle largely devoid of striation. Scape ca. (4–)5.5 dm tall, ca. 1 cm diam. proximally, ca. 5 mm diam. distally; bracts ovate-lanceolate, 25–36(–47) mm long, (5–)7–10 mm wide at the base. Flowers (3–)5(–6); usually pendent, sometimes only declinate, not fragrant; pedicels 5–10(–20) mm long, very rarely less than 5 mm; tube (25–)33–45 mm long, cylindrical and (1.5–)2–2.5(–3) mm for most of its length, abruptly dilated near the throat to (7–)8–10(–12) mm wide, usually curved gradually, but sometimes only curved abruptly at the base, in which case nearly straight for most of its length; tepals spreading widely from the throat (ca. 90°) or sometimes only at an angle of 45–60°; outer tepals ovate-lanceolate, (18–)21–28(–32) mm long, 8–11(–15) mm wide, apiculate; inner tepals ovate, (16–)20–26(–32) mm long, (10–)12–15(–17) mm wide, obtuse to acute. Staminal cup subcylindrical, 9–12(–15) mm long to apex of filament, (10–)12–15(–18) mm wide, deeply cleft between each stamen to 3–5 mm, usually edentate but variably lobed, acutely or obtusely bidentate, or irregularly toothed between each stamen, marked pale green to greenish yellow proximally; each stamen (3.5–)4–5 mm wide at the base, 4–6(–7) mm long, either trapezoidal in shape (in which case dilating gradually from apex to base), or abruptly dilated at ½–¼ of its length (in which case the upper portion narrowly subulate and 2–3 or 3–4 mm long, 1.5–2 mm wide); anthers oblong, 3.5–4.5 mm long; pollen grain 45.7–49.65 μm polar diam., 66.8–68.43 μm longest equatorial diam. Style (30–)45–60 mm long, exserted 0.5–1 cm beyond anthers; stigma 2–3 mm wide. Ovary globose or ellipsoid and deeply trigonous, rarely not trigonous, 5–8 mm long, 4–6(–6.5) mm diam., usually wider than long when deeply trigonous; ovules 2–3(–4, very rarely 5) per locule, superposed in the lower half of the cell. Capsule 1.5–2 cm long, 2–3 cm wide, bright orange, leathery; pedicels 15–27 mm long; seeds 1–2 per locule, ellipsoid, ca. 1 cm long, 0.5 cm diam., with a lustrous, smooth, black testa. Chromosome number: 2n = 92.

KEY TO THE VARIETIES OF *E. BOUCHEI*

1a. Staminal cup edentate, or occasionally with one obscure tooth at the base of one stamen; stamens trapezoidal and gradually dilated from apex to base or, if obscurely constricted distally, subulate portion more than 2 mm wide; Coclé and Colón provinces of Panama, rare in Panamá Province and in Costa Rica and Guatemala ..... 5a. *E. bouchei* var. *bouchei*

1b. Staminal cup lobed or toothed; stamens abruptly

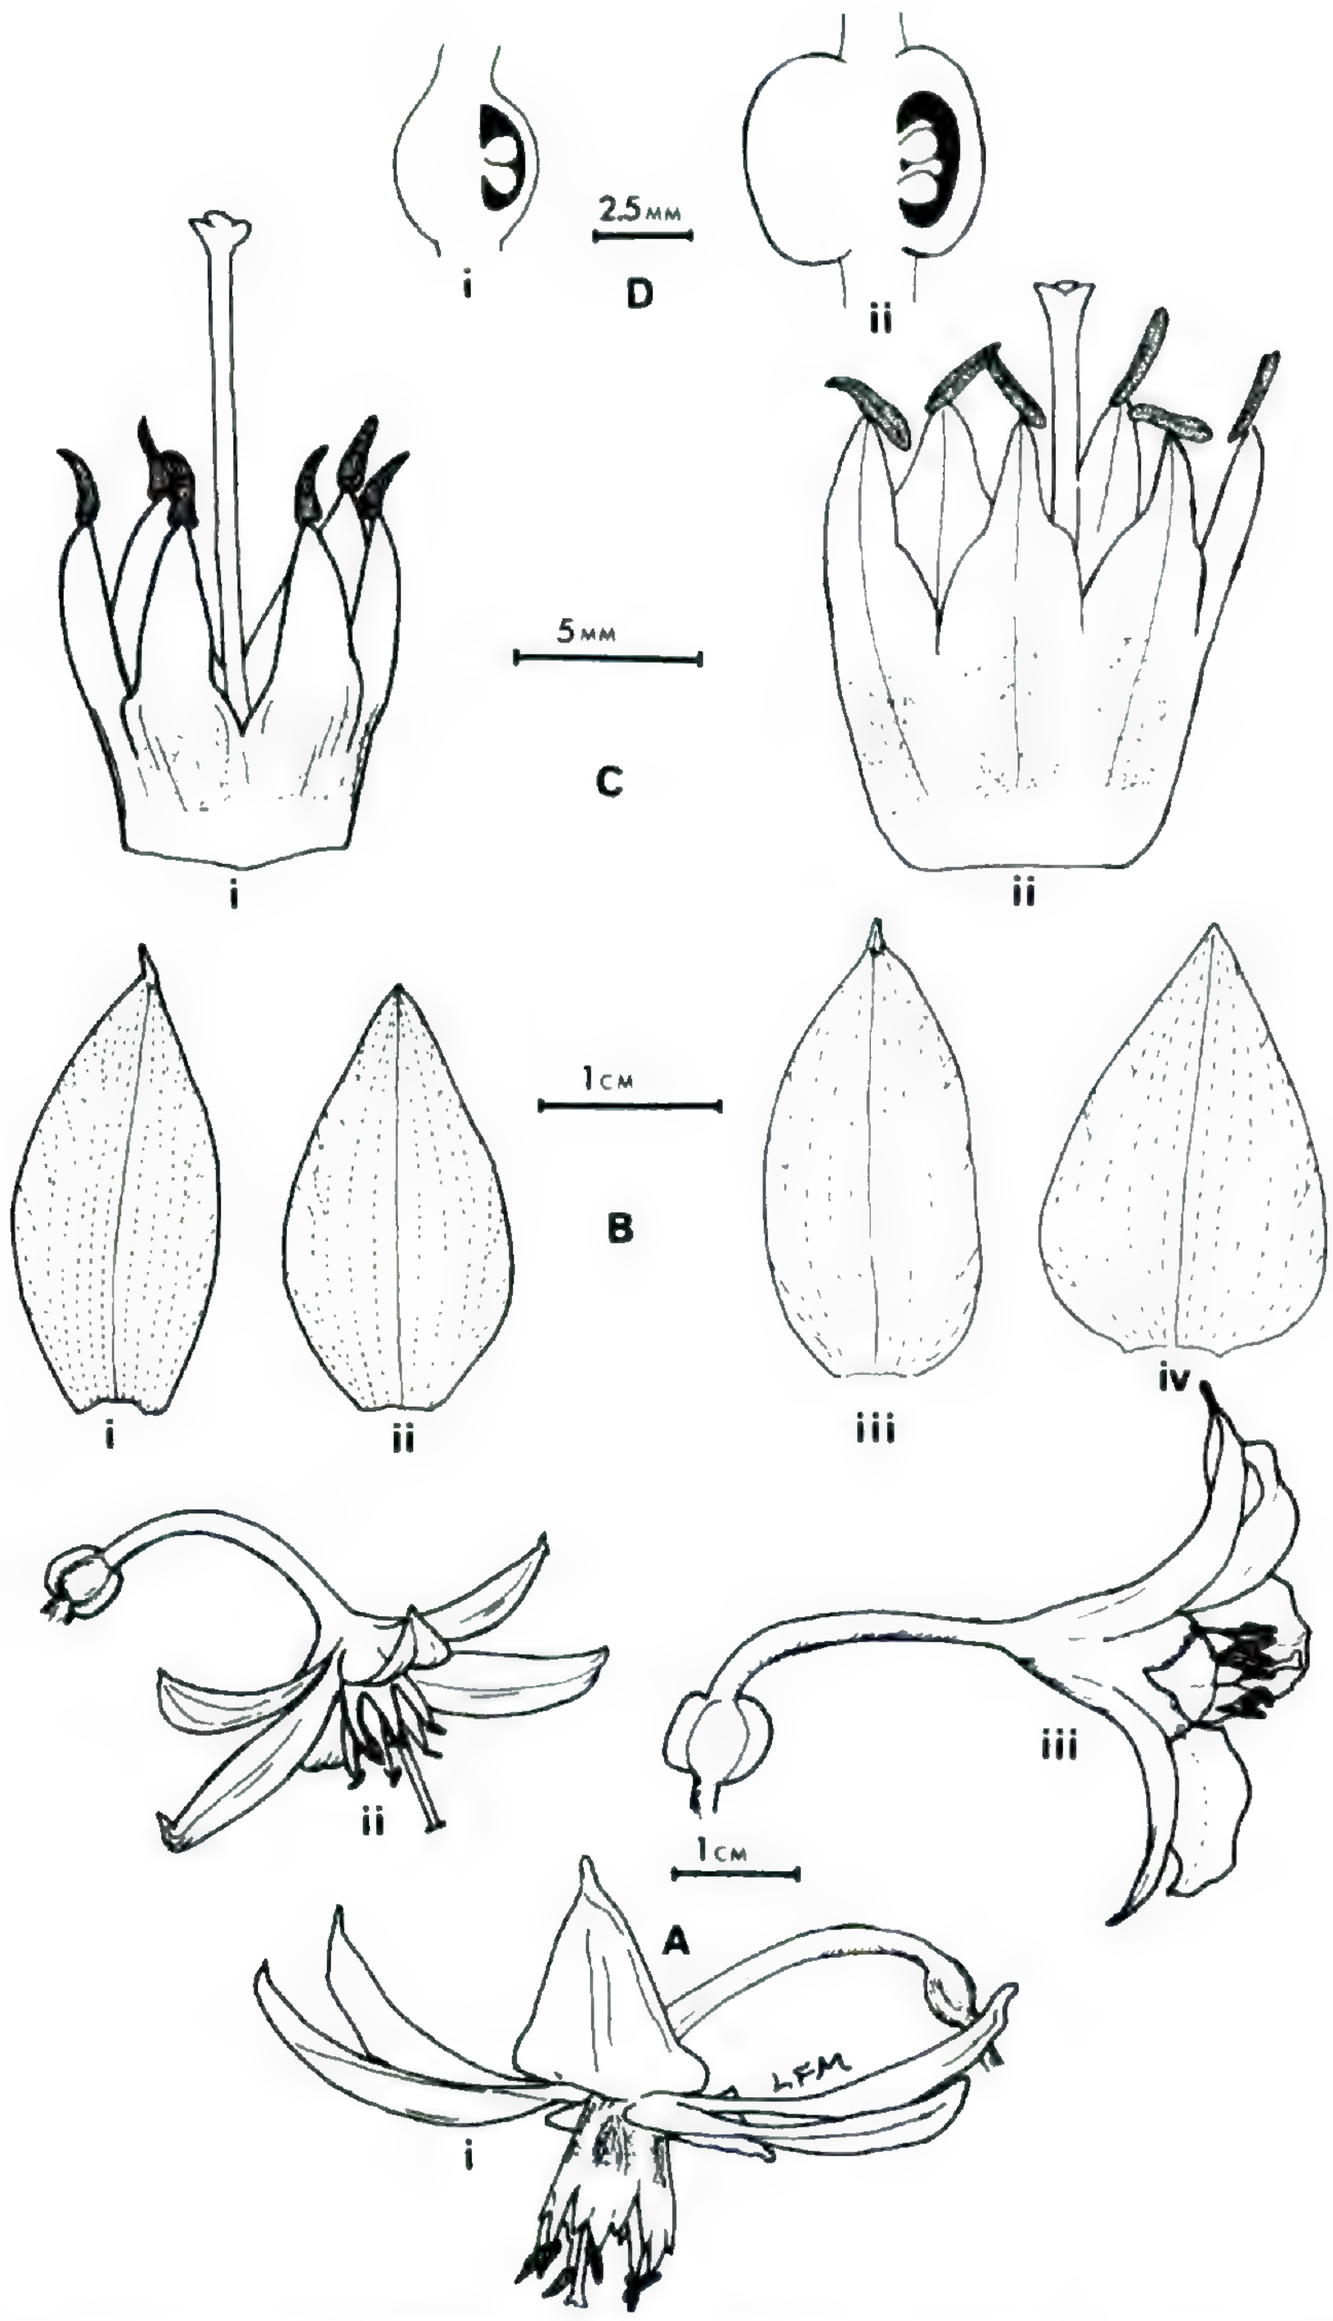

FIGURE 82. *Eucharis bouchei*.—A. Flowers. i. Variety *dressleri* (holotype, *Meerow 1107*, FLAS). ii, iii. Variety *bouchei*. ii, *Meerow 1125* (FLAS); iii, *Meerow 1157* (FLAS).—B. portion wider than 2 mm. Style exserted ca. 1 cm beyond the anthers. Ovary trigonous; ovules 2–3(–4) per locule.

Distribution. Understory of primary, premontane and lower montane rain forest in Coclé and Colón provinces of Panama (Fig. 83), particularly in the vicinity of El Valle de Antón and the Río Guanche valley; rare in Panamá Province, Costa Rica, and Guatemala (Fig. 84); frequently on steep slopes; (200–)500–1,000 m. Flowering (March) June–August, October–December.

Additional specimens examined. COSTA RICA. PUNTARENAS: Canton de Osa, hills near Palmar Norte, Río Grande de Terraba, 2,000 ft., *Allen 5347* (F, K, MO, US); cataratas de San Ramón, 26 Feb. 1931, *Brenes 13515* (F). SAN JOSÉ: El Rodeo, Mar. 1931, *Lankester s.n.* (F). GUATEMALA. SUCHITEPEQUEZ: Finca Moca, steep, bushy slope, 3,300 ft., 31 Oct. 1934, *Skutch 1585* (F). PANAMA. COCLÉ: lower Río Antón, vic. El Valle de Antón, 800–1,000 m, 30 Dec. 1936, *Allen 120* (GH, MO); vic.

of El Valle de Antón, 600–1,000 m, *Allen 1228* (GH, MO); vic. El Valle de Antón, ca. 600 m, 10 Dec. 1939, *Allen 2063* (MO); hills north of El Valle de Antón, 100 m, 14 Aug. 1940, *Allen 2182* (MO); region north of El Valle de Antón, ca. 1,000 m, 21 Aug. 1946, *Allen 3641* (G); La Mesa, above El Valle, 600–800 m, 18 Jan. 1968 (fr), *Duke & Dwyer 15180* (NY); 1–3 mi. 5b. Eucharis bouchei var. **dressleri** Meerow, var. nov. TYPE: Panama. Coclé: El Valle de Antón, from bulbs collected by R. Dressler in Panama, flowered in cultivation, 17 Mar. 1983, *Merrow 1107* (holotype, FLAS). Figure 82Ai.

Varietas haec ab varietas typica differt staminibus acute dentatis ad 1.5–2.7 mm distale concratis, ovario non trigono, et ovulis in quoque loculo aliquando plurimioribus.

Perianth tube 30–41 mm long; outer tepals 26.2–32 mm long, 6–10 mm wide; inner tepals 24–28 mm long, 9–13.5 mm wide. Staminal cup 10–16 mm long (to apex of filaments), 9.5–11.5 mm wide, irregularly toothed (some stamens lobed or quadrate), the teeth acute and 1.5–2.7 mm long; each stamen distally constricted abruptly at ½ length, the subulate portion 3.5–4.5 mm long, ca. 1.8 mm wide. Style exserted ca. 0.5 cm beyond the anthers. Ovary not trigonous; ovules 2–4 per locule.

This variety is named in honor of Robert L. Dressler, well-known tropical biologist.

Distribution. Rare rain forest understory herb in Coclé Province of Panama (Fig. 83), in the vicinity of El Valle de Antón, ca. 900 m. Flowering in June.

Additional specimens examined. PANAMA. COCLÉ: El Valle de Antón, 900 m, 4 June 1939, *Alston 8727* (BM).

5c. Eucharis bouchei var. **darienensis** Meerow, var. nov. TYPE: Panama. Darién: valley between Cerro Pirre and next most southerly peak, July 1977, *Folsom 4402* (holotype, MO). Figure 70Civ.

Varietas a *Eucharis bouchei* var. *dressleri* affinis sed differt staminibus obtuse dentatis vel lobis et parte staminea distale subulata breviore.

Perianth tube 25.5–36(–43.4) mm long; outer tepals 20–26 mm long, 8–11 mm wide; inner tepals 10.5–24 mm long, (11–)12–15(–16.5) mm wide. Staminal cup 9–10(–13, 16) mm long (to apex of filaments), 12–14.5(–18) mm wide, obtusely bidentate or lobed, the teeth when present ca. 1–1.5 mm long; each stamen distally constricted abruptly at ½–¼ length; the subulate portion ca. 1.7–3 mm long, 1.5–2 mm wide. Style exserted less than 0.5 cm beyond the anthers. Ovary trigonous; ovules 2–5 per locule.

The varietal epithet refers to Darién Province of Panama, where *E. bouchei* var. *darienensis* is most frequently collected.

Distribution. Understory of primary rain forest in Darién Province of Panama (Fig. 83); rare in Panamá Province and in Guatemala (Fig. 84); 480–1,450 m. Flowering January–February and June–August(–November).

Additional specimens examined. GUATEMALA. SOLOLA: between St. Pedro and Sta. Lucia, 20 Jan. 1857, *Wendland 207* (GOET). PANAMA. DARIÉN: La Boca de Pirre, 13 Oct. 1967 (fr), *Bristan 1285* (MO); vicinity of airstrip at Cana gold mine, 480 m, disturbed forest, 29 July 1976, *Croat 37956* (AAU); Cerro Pirre, cloud forest and/or mossy forest, 2,500–4,500 ft., Aug. 1967, *Duke & Elias 3661* (GH, MO, US); Cerro Tacarcuna, south slope, 1,250–1,450 m, 26 Jan. 1975, *Gentry & Mori 13945* (MO); 0–2 mi. E of Tres Bocas, along shortest headwaters of Río Cuasi, premontane rain forest, 28 Mar. 1968 (fr), *Kirkbride & Duke 1175* (MO); vicinity Cana, 1,750 ft., rare on forest floor, 23 June 1959, *Stern et al. 499* (GH); gold mine at Cana, 480 m, 26 July 1976 (fr), *Sullivan 626* (MO); trail northwest of Cana, 600 m, 28 July 1976 (fr), *Sullivan 718* (MO); gold mine at Cana, 480 m, 29 July 1976 (fr), *Sullivan 753* (MO); Cana–Cuasi trail, Chepigano, 2,000 ft., 12 Mar. 1940 (fr), *Terry & Terry 1533* (F). PANAMÁ: stream flowing out of Serranía de Maje, 10 Feb. 1977 (fr), *Folsom & Collins 1725* (MO); Maje, 5 mi. up Río Maje, steep forested ridge above Chocó Indian trail, 400 m, 19 Nov. 1970, *Kennedy 680* (MO, US); woods around La Eneida, 1,000 m, 5 Aug. 1970 (fr), *Luteyn & Kennedy 1761* (F); lower slopes and trail to Cerro Campana, 13 Sep. 1975, *Witherspoon & Witherspoon 8372* (MO).

Eucharis bouchei is the northernmost species of *Eucharis*, and the only species found north of the Darién Gap. It is also the most variable species in the genus, in characteristics that elsewhere justify specific delimitation. Patterns of variation in floral size and tube and limb habit form a complete mosaic throughout the range of *E. bouchei* that shows little or no geographic consistency (Meerow, 1987d). Staminal cup morphology (Fig. 70C) does, however, demonstrate a fair degree of geographical consistency, and it is chiefly on this basis that I have recognized var. *bouchei* and var. *darienensis*. Variety *dressleri*, rarely enountered mixed with var *bouchei*, presents a special case, discussed below.

Variety *bouchei*, most common around El Valle de Antón in Coclé Province, is recognized by its largely edentate staminal cup in which the trapezoidal free filament is not markedly constricted distally into a narrow subulate portion (Figs. 70Ci, ii, 82C). The staminal cup of variety *darienenis*, found both in Panamá and Darién provinces, is obtusely bidentate or lobed (Fig. 70Civ). The free filament constricts distally into a narrow (< 2 mm) subulate portion. These two varieties occur in close proximity in one location, near Cerro Campana in Panamá Province (Fig. 83).

The rare var. *dressleri* (Fig. 82Ai), with its acutely toothed staminal cup (Fig. 70Ciii) and shallowly trigonous ovary, occurs close to populations of var. *bouchei*, which is an unstable tetraploid, producing at least some cells with diploid ($2n$ = 46) chromosome number (Meerow, 1987d). This variety also does not express either heterozygous or additive banding phenotypes for isozymes of aspartate amino transferase, which otherwise characterizes electrophoretic phenotypes of *E. bouchei* (Meerow, 1987d).

The unprecedented degree of variation in *E. bouchei* is likely the result of two main factors: (1) the species is tetraploid, and (2) it probably represents a geologically recent colonization of Central America by this primarily northern Andean and Amazonian genus (Meerow, 1987d).

Northwesternmost populations representing var. *bouchei* have the most derived androecial morphology (Fig. 70Ci, ii) relative to southeasterly populations (var. *darienensis*, Fig. 70Civ). The latter have staminal cups similar to the generalized morphology characteristic of Andean and Amazonian species of subg. *Eucharis*. This suggests that general movement of *E. bouchei* in Central America has been away from the Colombian border. The occasional presence of *E. bouchei* in Costa Rica is not surprising, but the two reported collections from Guatemala (*Wendland 207* and *Skutch 1585*) represent a substantial disjunction, or two disjunctions, since the two collections represent different varieties. Given the history of cultivation of Amazonian *Eucharis* by Indian people for medicinal, ceremonial, and possibly ornamental use, the same may have held true in Central America.

6. Eucharis astrophiala (Ravenna) Ravenna, Phytologia 57: 95–96. 1985. *Urceolina astrophiala* Ravenna, Pl. Life 38: 49. 1982. TYPE: Ecuador. Cotopaxi: Quevedo–Latacunga road, km 46 from Quevedo, 79°11′W, 0°55′S, 600 m, 4 Apr. 1973, *Holm-Nielsen et al. 2851* (holotype not seen, AAU; isotype, S). Figure 85.

Bulb globose, 4–5 cm long, 3–4 cm wide, usually without an appreciable neck, tunics tannish brown. Leaves 2–4 at anthesis, elliptic- or ovate-lanceolate; petiole 10–20 cm long, 4–5.5 mm thick; lamina 15–25 cm long, 5–10 cm wide, thin, nonlustrous, deeply plicate and pustulate, adaxial surface light green, the white midrib conspicuous; abaxial surface whitish green; margin slightly undulate; apically acuminate; basally attenuate to the petiole. Scape 3–4(–5) dm tall, ca. 5 mm diam.; bracts 29–35(–40) mm long, lanceolate. Flowers 5–8(–10); pedicels 8–14 mm long; tube 28–35 mm long, ca. 2 mm wide for most of its length, dilating to (4–)5–6 mm at the throat, strongly curved; perianth limb spreading to 4–5 cm wide; outer tepals 25–30 mm long, (7–)10 mm wide, lanceolate, apiculate; inner tepals 25–28 mm long, 10–12(–14) mm wide, ovate-lanceolate to ovate, acute. Staminal cup funnelform-cylindrical, (10–)12–14 mm long, 8–12 mm wide, edentate, stained orange-yellow basally, cleft between each stamen for ½–⅔ of its length; each free filament (5–)6.4–6.9 mm long, ca. (2.5–)3.5–4.5 mm wide at the base, deltoid; anthers oblong, 5–5.5 mm long; average pollen grain 58.6–60.6 μm polar diam., 83.0–86.1 μm longest equatorial diam. Style 50–55 mm long, exserted 5–10 mm beyond the staminal cup; stigma 3-lobed, ca. 2 mm wide. Ovary globose-trigonous, 3.9–4.5 mm long, 3.2–4 mm wide, white at anthesis; ovules 2–3(–4) per locule, medially superposed. Capsule ca. 1–1.5 cm long, 2–2.5 cm wide, bright orange, leathery; seeds 1–2 per locule, ellipsoid, ca. 1 cm long, 0.5 cm diam., with a lustrous, smooth black testa. Chromosome number: $2n$ = 46.

Distribution. Endemic to the western declivity of the Andes in north-central Ecuador (Fig. 86), particularly in contiguous areas of Cotopaxi, Los

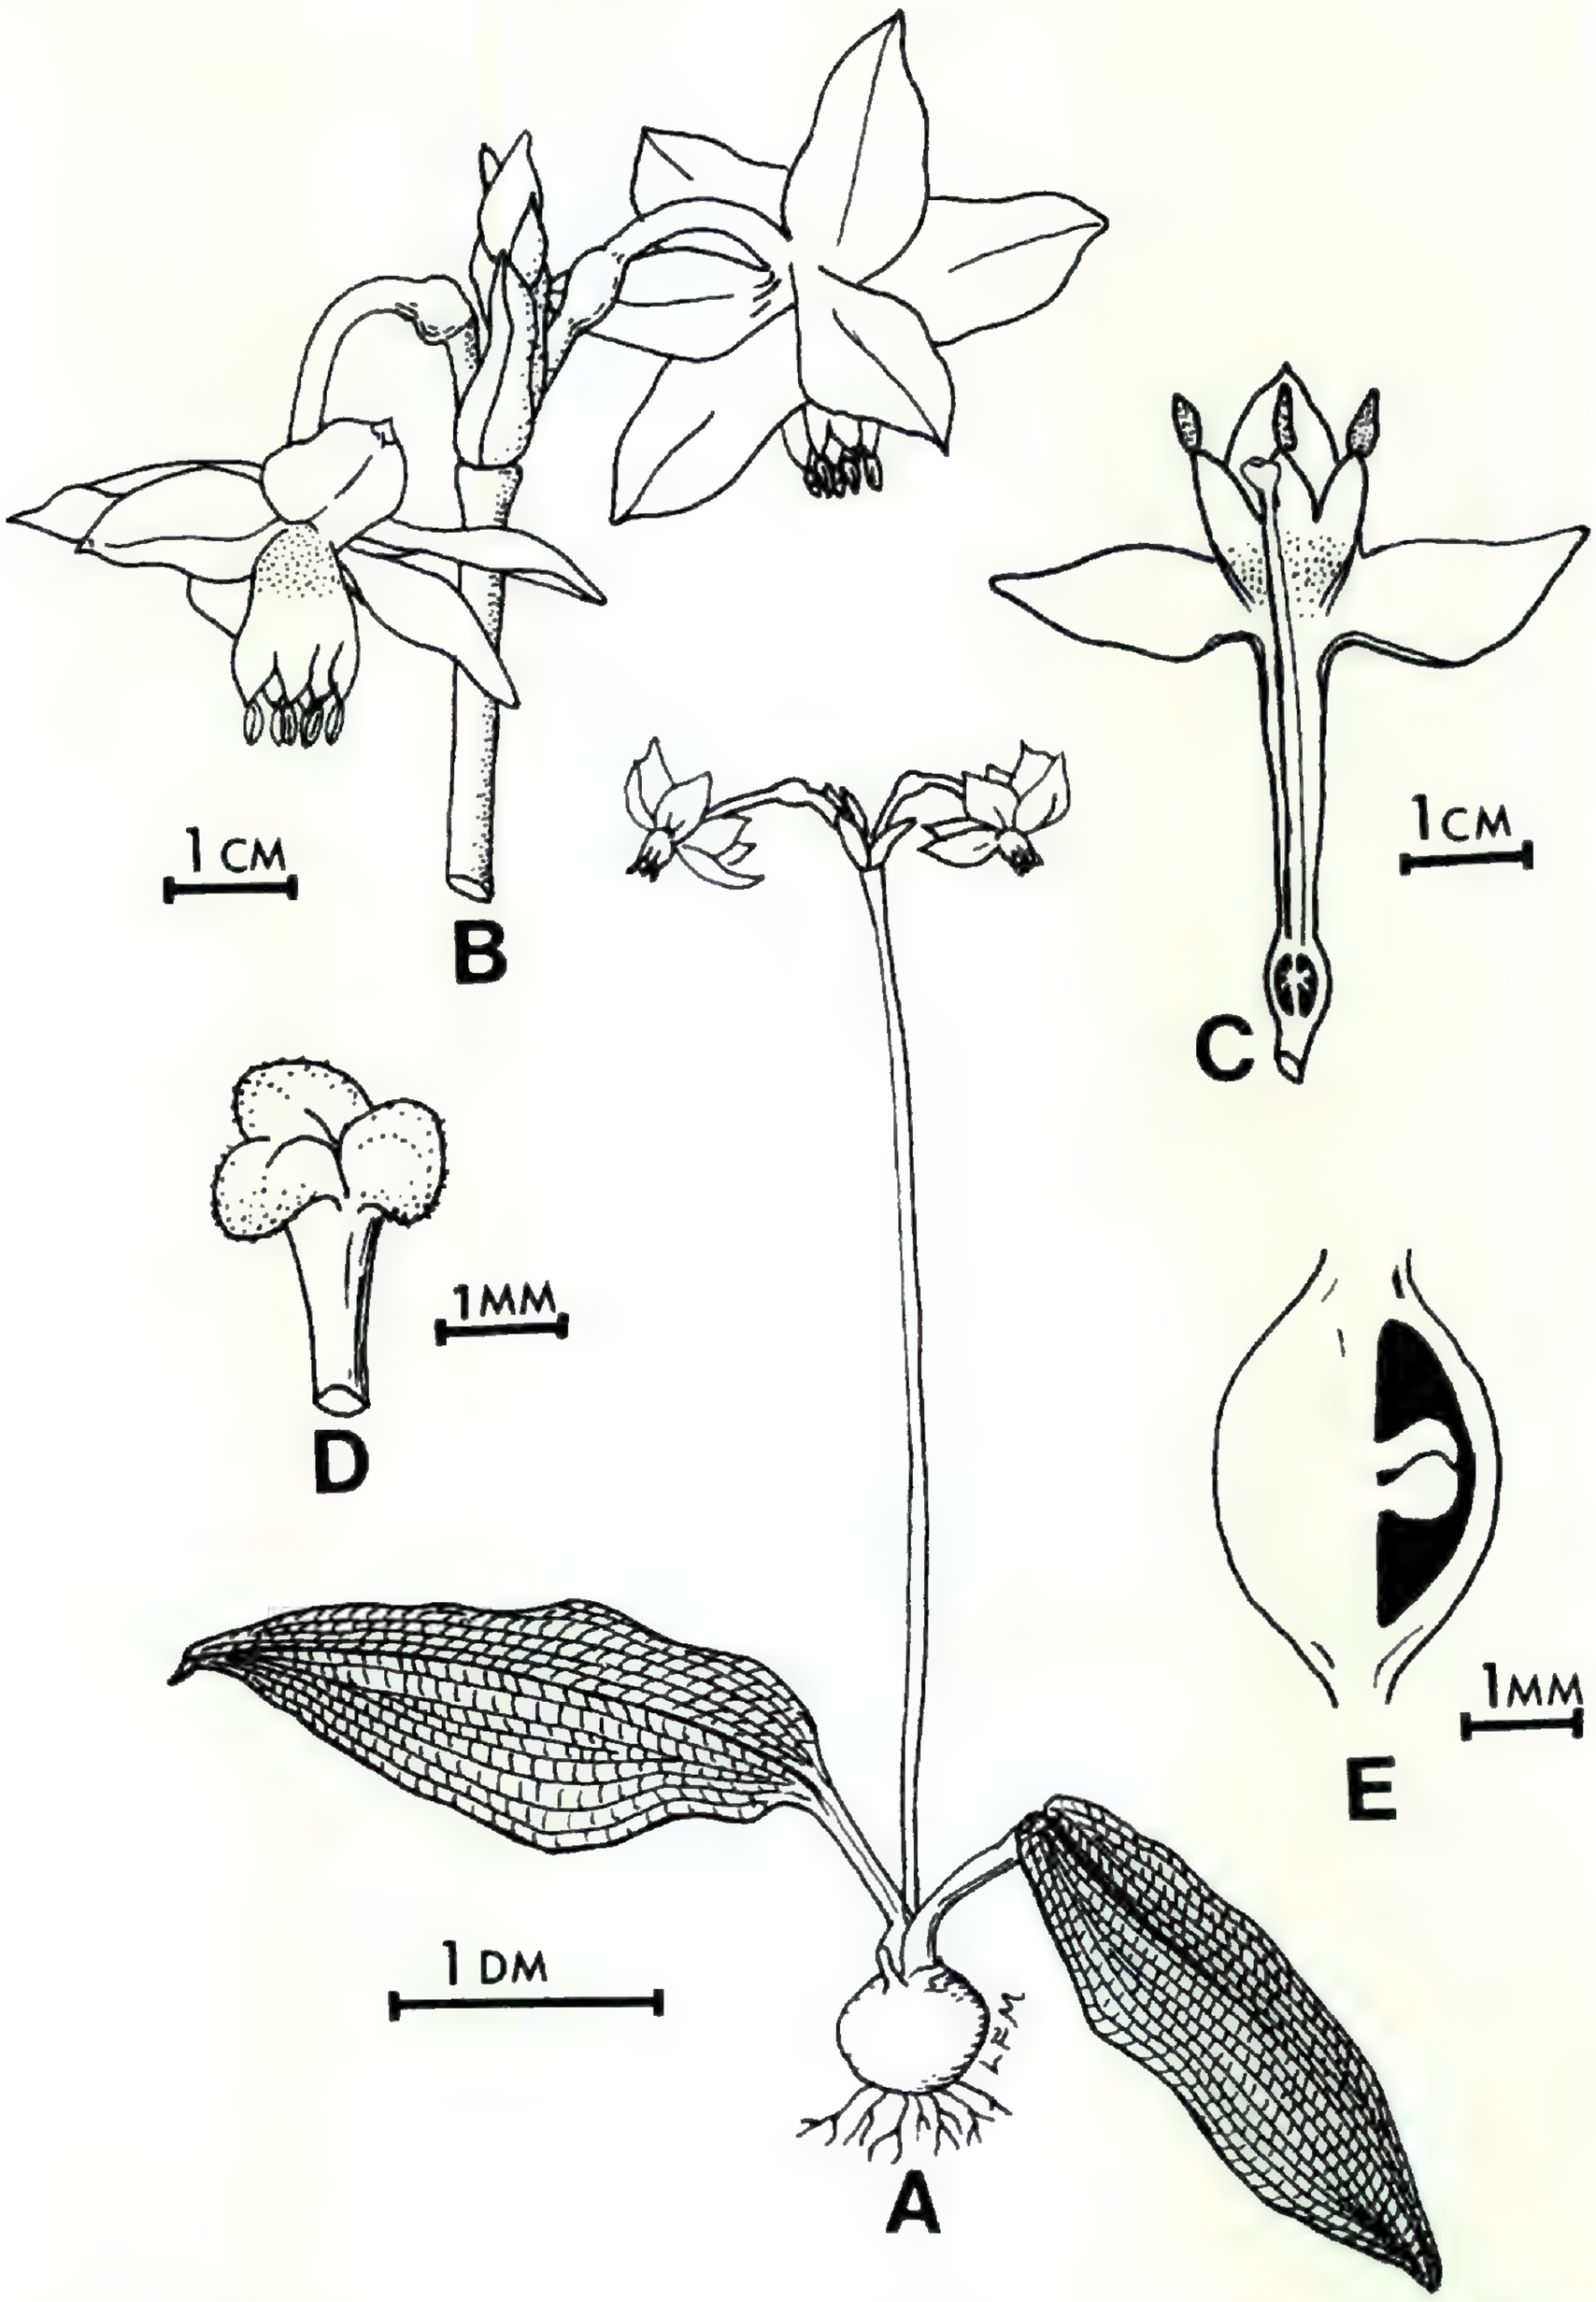

FIGURE 85. *Eucharis astrophiala*, adapted from a drawing by Boots N. Culbertson of *Dodson et al. 7122* (SEL).—A. Habit.—B. Inflorescence.—C. Flower, longitudinal section.—D. Stigma.—E. Ovary, longitudinal section.

Ríos, and Pichincha provinces, occupying the understory of lower montane rain forest (250–)400–800(–1,100) m elevation. Sporadic flowering may occur at any time but is concentrated in the wetter months of the year.

Additional specimens examined. ECUADOR. BOLÍVAR: Limón, 800–1,100 m, 14 Oct. 1943, *Acosta-Solís 6374* (F). FIGURE 86. Distribution of *Eucharis astrophiala* in Ecuador.

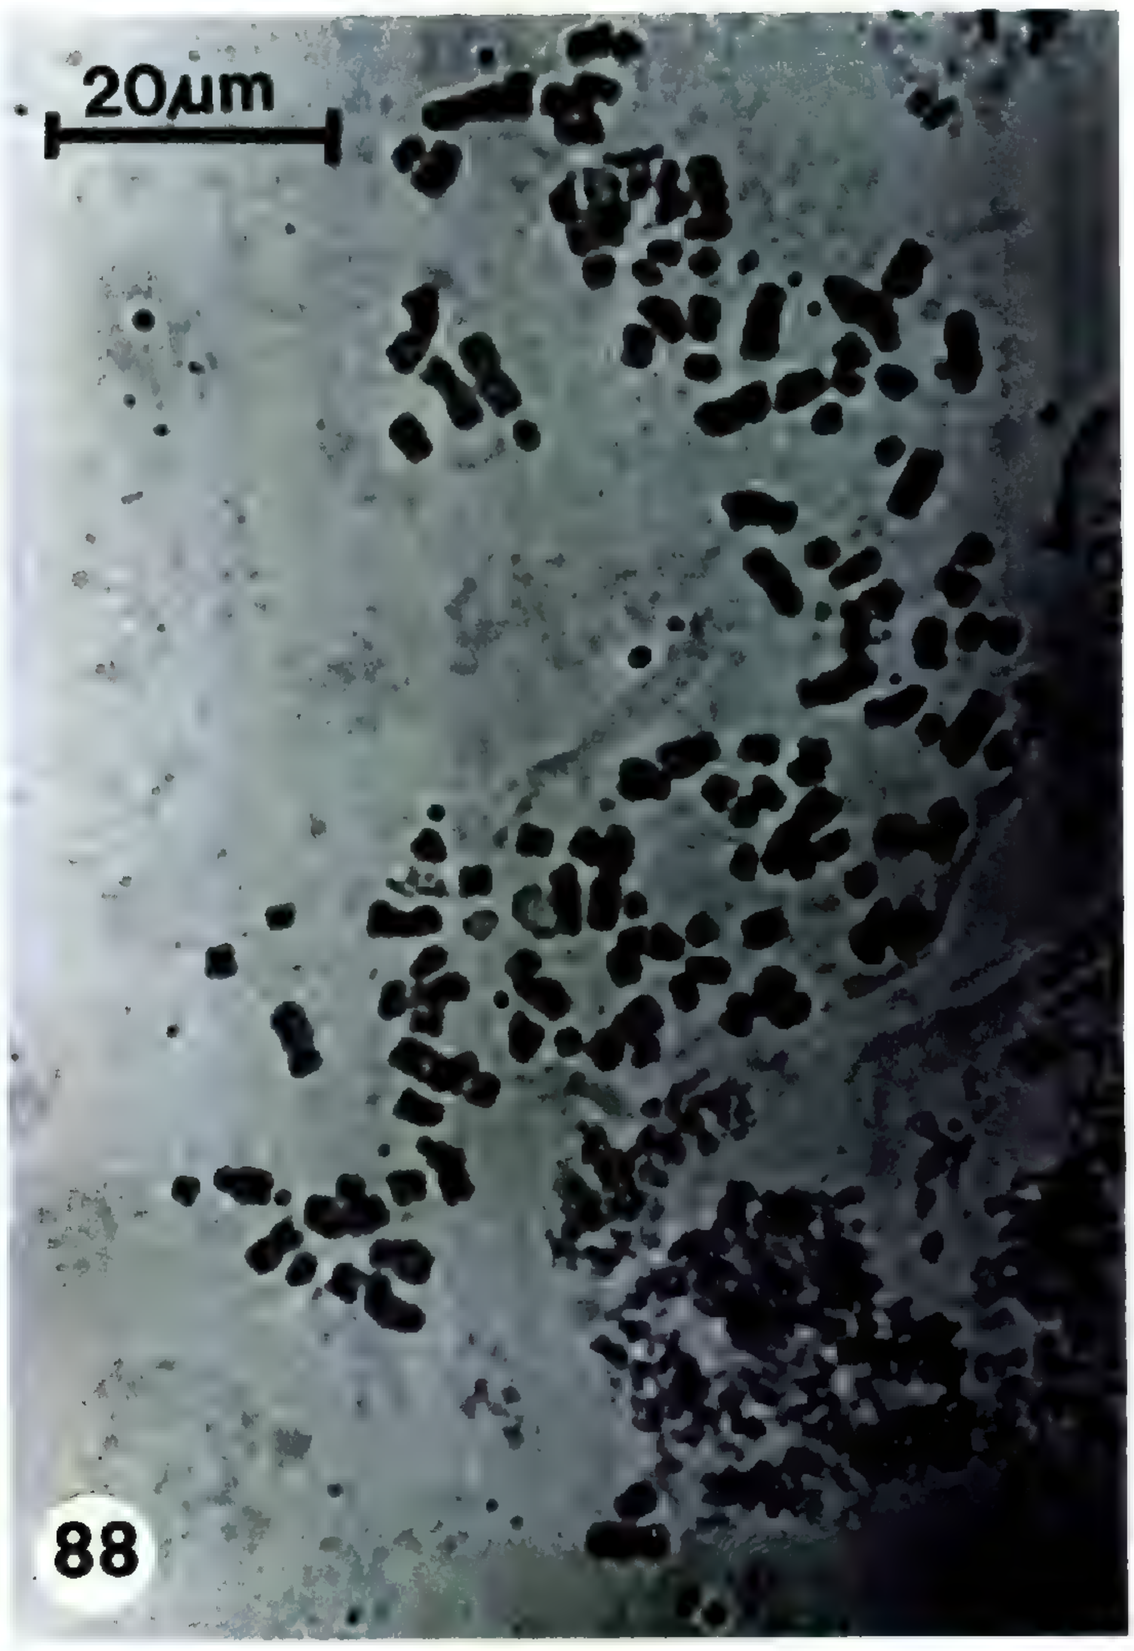
Dodson & Duke 7714 (MO, SEL); road from Patricia Pilar to 24 de Mayo at km 12, path following ridge line at El Centinela at crest of Montañas de Ila, 600 m, 6 Apr. 1980, *Dodson & Gentry 10298* (MO, SEL); Centinela, km 12 on road from Patricia Pilar to 24 de Mayo, km 47 Santo Domingo–Quevedo, 650 m, 30 July 1984, *Dodson et al. 14666* (MO); Centinela, 12 km W of Patricia Pilar, km 45 Santo Domingo–Quevedo, 600 m, 2 Feb. 1985, *Dodson & Neill 15532* (MO); Reserva Endesa, ca. 6 km WNW of P. Vicente Maldonado, mature rain forest, ca. 800 m, 24 Mar. 1985, *Harling & Andersson 23279* (GB); Reserva Forestal Endesa, Río Silanche, km 113 Quito–Puerto Quito, 10 km N of main highway, 0°5′N, 79°2′W, 650–700 m, 25 Feb. 1984, *Jaramillo 6439* (GB); Endesa, km 113 Quito–Puerto Quito, 750 m, 23–24 Apr. 1983, *Rodriguez et al. 91, 92 & 93* (QCA); Santo Domingo de los Colorados, Rancho Brahman, ca. 10 km NW of the town on road to Esmeraldas, 400 m, 31 Mar. 1967, *Sparre 15216* (S).

Eucharis astrophiala is easily separated from the other small-flowered species of subg. *Eucharis* by its uniquely bullate-pustulate and nonlustrous ovate-lanceolate leaves; edentate and deeply cleft staminal cup with deltoid free filaments (Fig. 85B, C); and the second-largest pollen grain in the genus (the largest is that of *E. caucana*). The largest



FIGURES 87, 88.—87. *Eucharis caucana* (type collection).—88. Root-tip mitotic metaphase chromosome configuration of *E. caucana* ($2n = 138$, type collection). Thirteen chromosomes are out of the figure frame.

chromosome pair of *E. astrophiala* is submetacentric, unlike the metacentric pair of all other species of the genus I have examined (Meerow, 1987b). It is the only species of the subgenus found exclusively on the western slopes of the Andes south of Colombia. It occurs sympatrically in some localities (fide *Dodson & Gentry 12815* and *Meerow & Meerow 1140*) with *E. moorei*, though the latter grows at slightly higher elevation in these areas. *Eucharis astrophiala* is the only species of subg. *Eucharis* that enters a definite rest period during the short dry season of the northwestern and central western Ecuadorean Andes. New growth completely ceases, though one or two leaves may persist for the duration.

7. Eucharis caucana Meerow, sp. nov. TYPE: Colombia. Valle de Cauca: between La Paila and Zarzal, Hacienda El Medio, 975 m, 14 Apr. 1987, *Silverstone-Sopkin et al. 3064* (holotype, FTG; isotypes not seen, CUVC). Figure 87.

Species nova affinis *E. lehmannii* Regel sed floribus breviter pedicellatis grandioribus et paucioribus, staminibus edentatis, et ovulis paucioribus in quoque loculo differt.

Bulb subglobose, 52–60 mm long, ca. 34 mm diam., without an appreciable neck, tunics brown. Leaves 2–3; petiole 21–25 cm long, 7.2–10 mm wide; lamina ovate–elliptic, ca. 25.5 cm long, 10–11 cm wide, plicate, the margins undulate, acuminate, attenuate at the base. Scape 4–5 dm tall, ca. 1 cm diam. proximally, 5 mm diam. distally; bracts 26–27 mm long, 8 mm wide, ovate-lanceolate. Flowers 2–3, slightly declinate, funnelform-campanulate, not fragrant; pedicels ca. 6.5 mm long, ca. 2 mm diam.; tube ca. 32 mm long, 2 mm wide proximally, dilating in its distal ⅓ to ca. 9.2 mm at the throat, abruptly curved near its base, the dilated portion stained green internally; limb spreading to ca. 3.5 cm, the tepals diverging from the throat at angles of 75–90°; outer tepals ca. 20 mm long, 9.5–10.3 mm wide, ovate, apiculate; inner tepals ca. 18–19 mm long, 11.5 mm wide, ovate, acute to obtuse. Staminal cup ca. 3 mm long (to apex of lobes), edentate, stained green proximally; stamens connate only in the proximal 0.7–1 mm; each filament ca. 10 mm long, narrowly subulate and ca. 1 mm wide in the distal 4–5 mm,

then abruptly dilated proximally to 3 mm wide; anthers oblong, ca. 4 mm long, gray-brown; pollen white, the exine coarsely reticulate, 55–75 μm polar diam., 98–110 μm longest equatorial diam. Style white, ca. 50 mm long, exserted ca. 1 cm beyond the anthers; stigma ca. 2 mm wide, greenish white. Ovary globose-trigonous, 7–7.5 mm diam., ovules 4–6 per locule. Capsule leathery, orange, ca. 1.5 cm long, 2.5 cm wide; seeds 2 per locule, ellipsoid, ca. 10 mm long, ca. 5 mm wide with a smooth, lustrous black testa. Chromosome number: $2n = 138$.

Named for the Río Cauca valley of Colombia to which the species is endemic.

Distribution. Endemic to Valle de Cauca Department in the vicinity of La Paila in western Colombia (Fig. 81). The type location is a 12.5-hectare remnant of primary forest planted with cacao in which canopy trees were retained for shade (*Anacardium excelsum*, *Nectandra caucana*).

Additional specimen examined. COLOMBIA. VALLE DE CAUCA: La Paila, 30 May 1853 (fr), *Holton s.n.* (NY).

The recent receipt of material collected by Phil Silverstone-Sopkin and coworkers is the first collection of the subgenus in the largely deforested Cauca valley since 1922.

Eucharis caucana has the largest pollen grains in the genus and is the only known hexaploid species of *Eucharis*, with a somatic chromosome number of $2n = 138$ (Fig. 88). As with most other South American peripheral isolates from the Amazonian center of distribution for subg. *Eucharis* (*E. astophiala*, *E. corynandra*, *E. lehmannii*, and *E. oxyandra*), *E. caucana* exhibits some degree of morphological novelty; in this case, reduction of staminal connation, funnelform-campanulate perianth, and very large pollen grains. Nonetheless, *E. caucana* has fruit and seed morphology typical of subgenus *Eucharis*. By its reduced staminal cup *E. caucana* shows affinity with *E. lehmannii* from which it differs by having larger flowers, shorter pedicels, straighter tubes, edentate androecia, and fewer ovules per locule. By its high polyploid chromosome number, short pedicels, and flower size, *E. caucana* shows similarity to certain populations of *E. bouchei* var. *bouchei*. Some collections of the latter from Colón Province exhibit funnelform-campanulate perianth morphology and floral tube habit like *E. caucana*. The discovery of this hexaploid species in Colombia supports the hypothesis that a polyploid complex of *Eucharis* may have existed in Colombia in the recent geologic past (Meerow, 1987d).

8. **Eucharis ulei** Kränzlin, Bot. Jahrb. 50, Beibl. 111: 4–5. 1913. *Urceolina ulei* (Kränzl.) Traub, Pl. Life 27: 57–59. 1971. TYPE: Brazil. Amazonas: Juruá Miry, June 1901, *Ule 5737a* (holotype, B), non *Ule 5737b* (in fruit) (B) vel *Ule 5737* (MG). Figure 89B, C.

Eucharis ipariensis (Ravenna) Ravenna, Phytologia 57: 95. 1984. *Urceolina ipariensis* Ravenna, Pl. Life 38: 50–51. 1982. TYPE: Peru. Huánuco: Pachitea, Honoria, Bosque Nacional de Iparia, Río Pachitea, 20 km above confluence with Río Ucayali, near Miel de Abeja, 1 km from Tuernavista, 26 Apr. 1967, *Schunke 1887* (holotype not seen, NY; isotypes, F, COL, G, US).

Eucharis moana (Ravenna) Ravenna, Phytologia 57: 95. 1984. *Urceolina moana* Ravenna, Pl. Life 38: 50. 1982. TYPE: Brazil. Acre: Río Moa at Serra da Moa village, 27 Apr. 1971, *Prance et al. 12491* (holotype, NY; isotypes, K, MO, not seen: herb. Ravenna).

Eucharis boliviensis Ravenna, Phytologia 64: 218. 1988. TYPE: Bolivia. El Beni: Covendo, 600 m, 19 Aug. 1921, *White 930* (holotype, NY; isotype, K).

Bulb subglobose, (2.5–)3.5–4.5(–5) cm long, 2–3.5(–4.5) cm in diam.; neck 1–2 cm long, ca. 1.5 cm wide; outermost tunics gray-brown, inner tunics tan. Leaves 2–3; petiole (10–)18–30(–35) cm long, 5–6 mm thick; lamina (narrowly) elliptic (average length : width > 3), 18–25(–33) cm long, (5–)7–10(–12.5) cm wide, acute to shortly acuminate, attenuate at the base. Scape (35–)40–58 cm tall, 8–10 mm diam. proximally, 3–4 mm diam. distally; bracts lanceolate to ovate-lanceolate, (25–)30–37(–54) mm long, greenish white. Flowers (3–)(–7), pendent, without fragrance; pedicels (8–)11–15(–20) mm long, ca. 2 mm diam.; tube (25–)28–35(–37.5) mm long, curved gradually for most of its length, 1.5–2(–2.5) mm wide for most of its length, abruptly dilated just below throat to (6–)7–10 mm; limb spreading to 40–45(–55) mm wide; outer tepals ovate-lanceolate, 24–28(–32) mm long, (6.5–)8–10(–11) mm wide, apiculate; inner tepals ovate, 23–27(–30) mm long, (9–)10–13(–15) mm wide, acute. Staminal cup funnelform-cylindrical, 10–12 mm long (to apex of teeth or lobes), 11–13(–16) mm wide, usually bidentate between each free filament, rarely edentate, irregularly toothed, or the teeth obscure (in which case the stamens quadrately lobed), cleft between each stamen for (1.5–)2–3(–4) mm, with a ± rectangular, green zone in the proximal half of each stamen; teeth acute or obtuse, 0.5–0.7 mm long; each stamen 3.5–4.5(–5.5) mm wide from tooth to tooth; free filament subulate, (3–)4.5–6 mm long, (1–)1.5–2

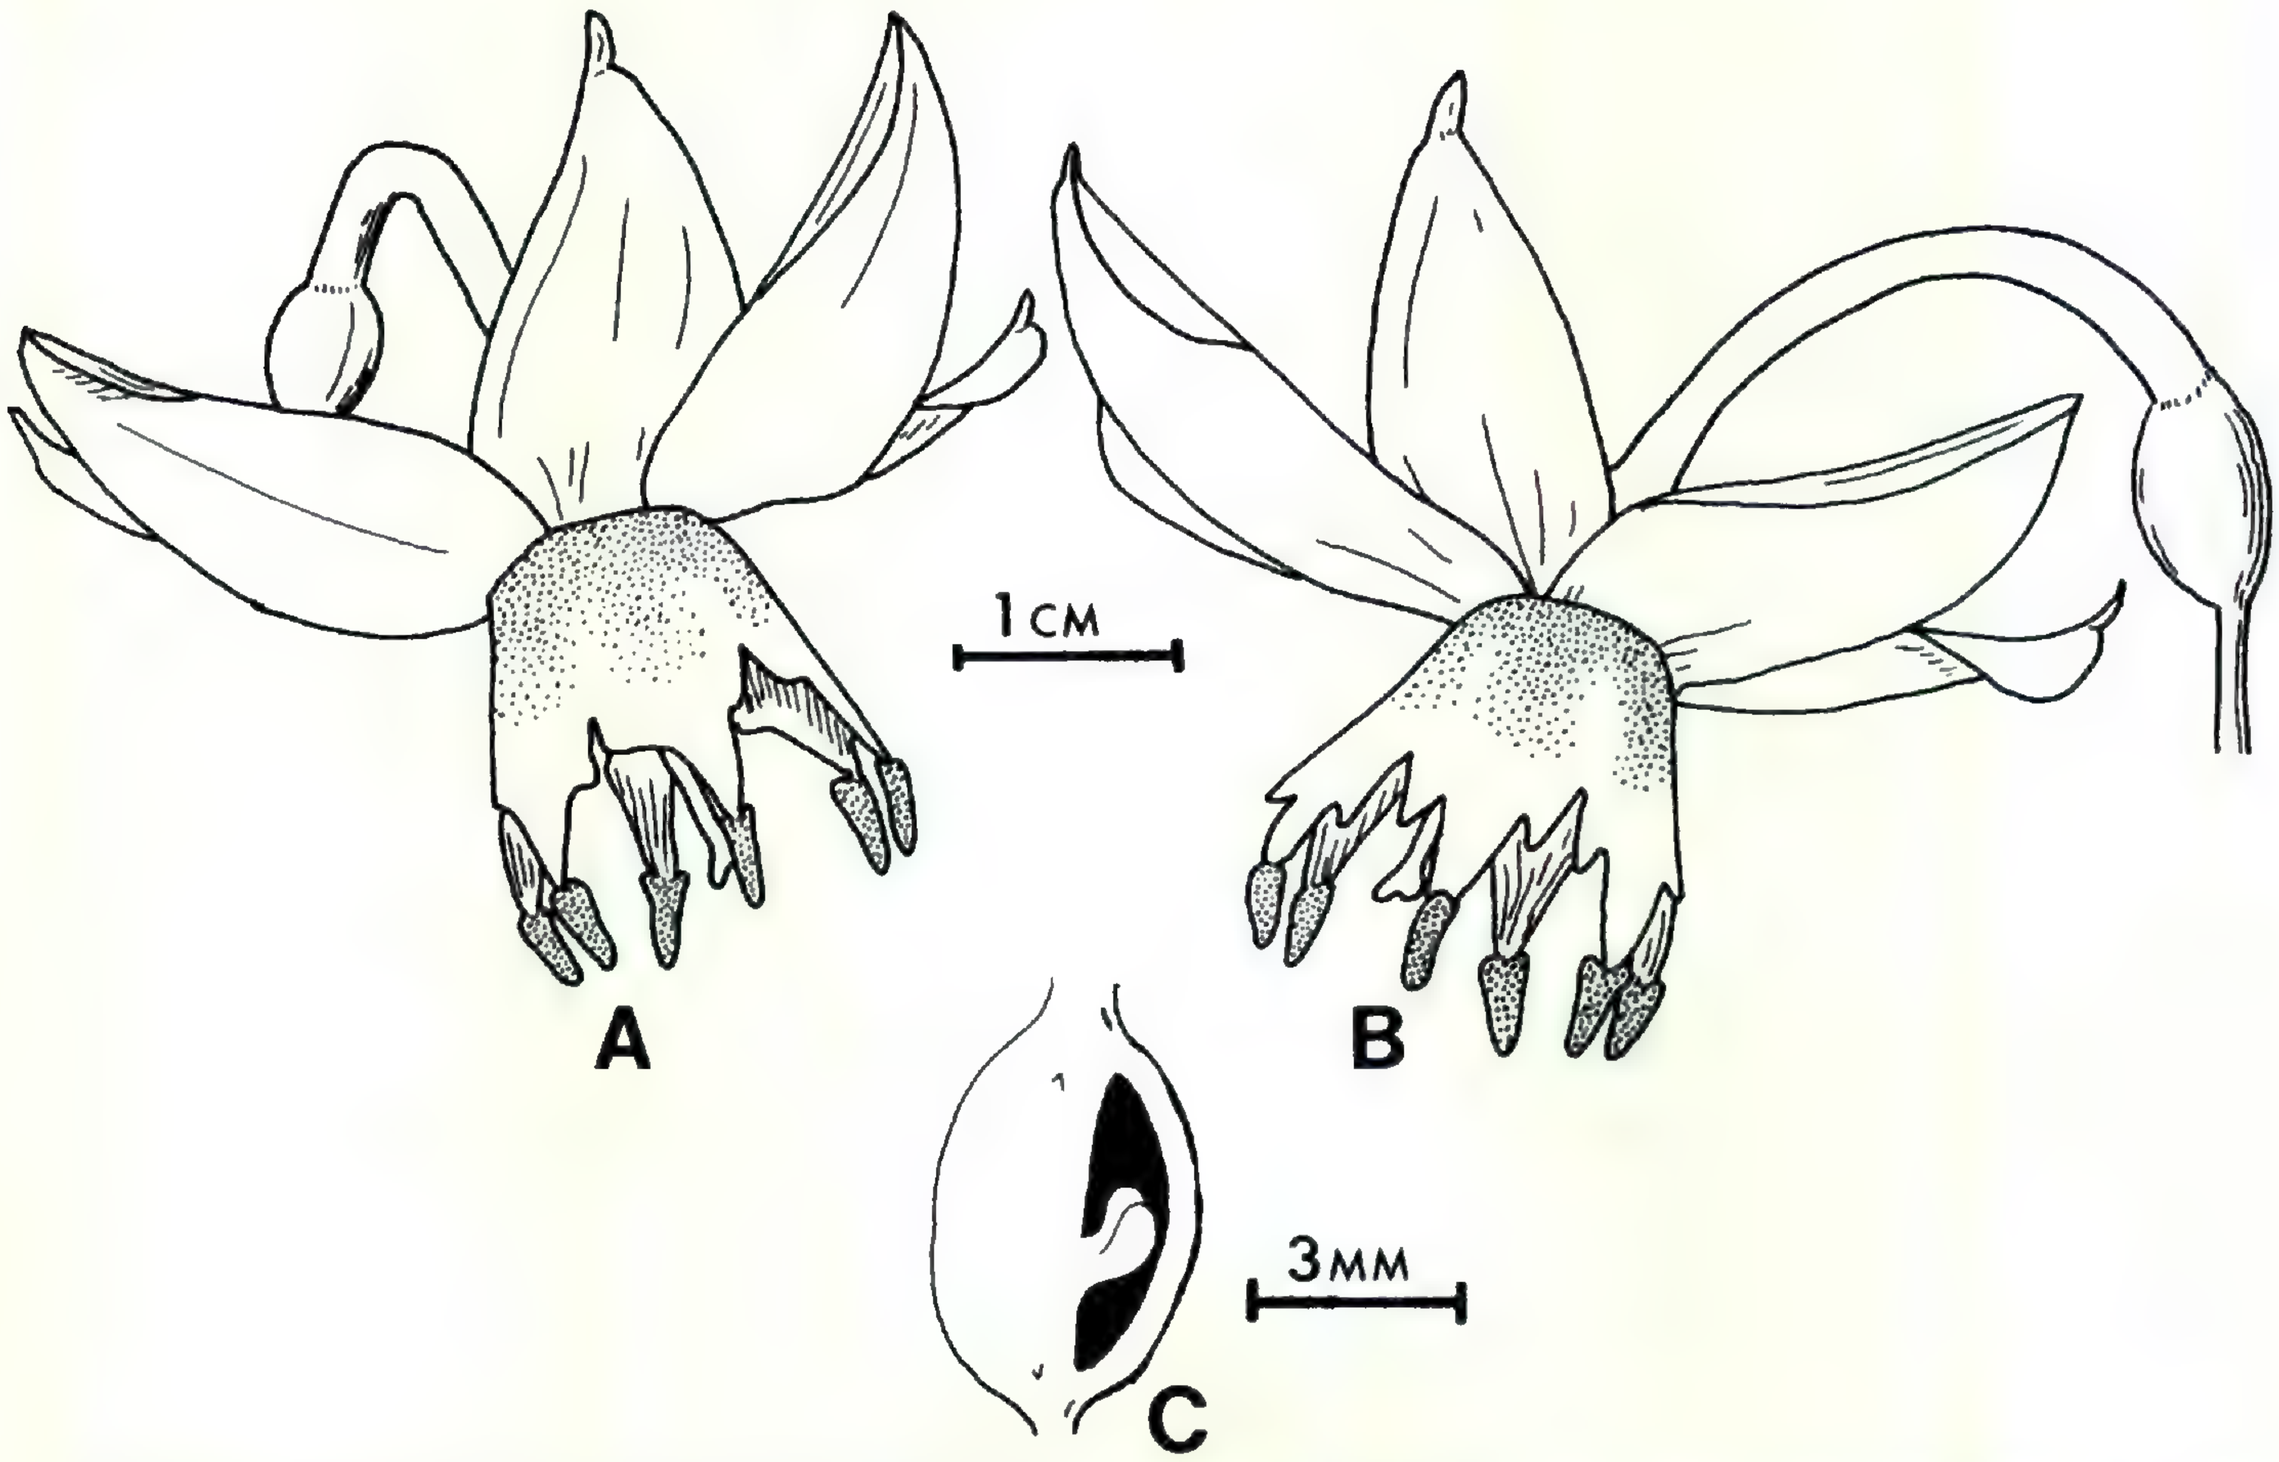


FIGURE 89. *Eucharis cyaneosperma* and *E. ulei*.—A. Flower of *E. cyaneosperma* (holotype, *Meerow 1032*, FLAS).—B. Flower of *E. ulei* (*Schunke 1887*, F).—C. Ovary of *E. ulei*, longitudinal section (*Schunke 1887*, F).

mm wide at its base; anthers oblong, 3–3.8 mm long; pollen grain ca. 49.35 μm polar diam., ca. 69.85 μm longest equatorial diam. Style (40–)45–50(–60) mm long; stigma 1.5–2.5 mm wide. Ovary globose-ellipsoid, 6–8.5(–10) mm long, 4–5.5 mm wide; ovules 2(–4) per locule, superposed in the lower half of the cell. Capsule 1.2–1.5 cm long, 2–2.5 cm wide, bright orange, leathery; pedicels 2–4 cm long; seeds 1–2 per locule, ellipsoid, 8–10 mm long, ca. 5 mm wide with a smooth, lustrous black testa.

Distribution. Understory of primary rain forest in the Amazon Basin and eastern Andean foothills, most common in Peru but sporadically encountered north to Colombia and south to Bolivia (Fig. 81), on fertile, usually noninundated, soils; 100–300(–1,000) m. Flowering at any time of the year, most frequently June–September.

Additonal specimens examined. BRAZIL. AMAZONAS: basin of Río Juruá, Foz da Tarauca, Yuma, rare, on varzea land, 1 June 1933, *Krukoff 4613* (NY); basin of Río Juruá, near mouth of Río Embira, 7°30′S, 70°15′W, 3 June 1933 (fr), *Krukoff 4637* (G, GH, K, NY, S, US); Río Purus, Río Itaxi, Seringal Jurucua, 120 km south of Labrea, 29 June 1971, *Prance et al. 13915* (MO, NY). PARA [?]: no data, *Ferreira s.n.* (P). COLOMBIA: AMAZONAS: Trapecio, confluencia de Río Loretoyacu con el Río Amazonas, Puerto Nariño, Mar. 1968, *Diaz-M 15* (COL); Trapecio amazonico, Boiauassu River, 100 m, Oct. 1946, *Schultes & Black 8608a* (US); Puerto Nariño, mouth of Río Loretoyacu, 100 m, 8 May 1972 (fr), *Plowman 3216* (COL, K). PERU. AMAZONAS: Río Santiago, canto de la Quebrada Caterpiza, 200 m, 11 Sep. 1979 (fr), *Huashicat 524* (MO); valle de Río Santiago, ca. 65 km norte de Pinglo, Quebrada Caterpiza, 2–3 km atras de la comunidad de Caterpiza, 200 m, 13 Oct. 1979 (fr), *Huashikat 930* (MO); same locality, 17 Dec. 1979, *Huashikat 1553* (MO); Monte del Isla, la isla 1 km bajo de La Poza, Río Santiago, 180 m, 8 Aug. 1979 (fr), *Leveau 7* (MO); same locality, 15 Aug. 1979 (fr), *Leveau 123* (MO); same locality, 8 Aug. 1979 (fr), *Pena 9* (MO). LORETO: Río Amazonas, SE of Iquitos, swampy forest, 17 Aug. 1972, *Croat 19289* (MO); Río Napo near Entrada de Isla Inayuga, edge of forest, 20 Sep. 1972 (fr), *Croat 20521* (MO); near Base Araguana, upper Río Mazán, ca. due north of Santa Maria de Nanay, noninundated forest, 9 July 1976 (fr), *Gentry & Revilla 16586* (MO); Maynas, Quebrada Yanomono, Explorama Tourist Camp, halfway between Indiana and mouth of Río Napo, mature noninundated forest on laterite, 4 Nov. 1979 (fr), *Gentry et al. 27438* (MO); Yanomeno, Explorama Tourist Camp, Río Amazonas above mouth of Río Napo, 72°48′W, 3°28′S, 130 m, upland forest on lateritic soil, 25 June 1982 (fr), *Gentry et al. 37204* (MO); Río Samiria, Flor de Yarina, ca. 5°2′S, 74°30′W, 160 m, noninundated restinga forest, *Gentry et al. 38103* (MO); Iquitos, ca. 100 m, 3–11 Aug. 1929, *Killip & Smith 27442* (US); Yurimaguas, lower Río Huallaga, ca. 135 m, 23 Aug.–7 Sep. 1929, *Killip & Smith 27656* (US); Río Marañon Valley, San Lorenzo, between mouths of Río Pastaza and Río Huallaga, 150 m, 20 Aug.–9 Sep. 1929, *Killip et al. 29227* (US); Iquitos, Muena-Caño, 105 m, 9 Feb. 1932, *Mexia 6504a* (F, UC); Maynas, Río Amazonas near Tamishiyacu, 3 Sep. 1976, *Revilla 1281* (MO); Pebas on Amazon

River, 25 July 1929 (fr), *Williams 1751* (F); Pebas on Amazon, 21 July 1929 (fr), *Williams 1787* (F); La Victoria on the Amazon, 21 Aug. 1929, *Williams 2629* (F); same locality as preceding, 29 Aug. 1929, *Williams 2938* (F); alto Río Itaya (San Antonio), 145 m, Sep.–Oct. 1929 (fr), *Williams 3398* (F); Puerto Arturo, Yurimaguas, lower Río Huallaga, 155–210 m, 16 Nov. 1929 (fr), *Williams 5148* (F). PASCO: Oxapampa, Palcazu valley, Cabeza de Mono, 5–6 km W of Iscosacin, 17–20 Apr. 1983, *Smith 3787* (MO); SAN MARTÍN: Mariscal Cáceres, Tocache Nuevo, Quebrada de Cachiyacu de Huaguisha, 570 m, 16 July 1982 (fr), *Meerow et al. 1023* (FLAS); Mariscal Cáceres, Tocache Nuevo, Quebrada de Cachiyacu de Huaguisha, 570 m, 16 July 1982, *Meerow et al. 1024* (FLAS); Mariscal Cáceres, Mirama, N of Tocache Nuevo, along left bank of Río Huallaga, 500 m, *Plowman & Kennedy 5811* (GH); Mariscal Cáceres, Tocache Nuevo, Fundo La Campina, 2 km abajo de Tocache Nuevo, margen derecha del Río Huallaga, 400 m, 7 Sep. 1969, *Schunke 3396* (F, US); Mariscal Cáceres, Tocache Nuevo, Quebrada de Cachiyacu, 3 km abajo de Puerto Pizano (margen derecha del Río Huallaga), 21 Apr. 1971. UCAYALI: Coronel Portillo, Yarina Cocha, Fundo "El Pescador," cerca al Caserio Nuevo Destino, al este de Yarina Cocha, 150 m, 31 Oct. 1984, *Schunke 14153* (FLAS).

Eucharis ulei is among the more widespread Amazonian taxa of subg. *Eucharis*, extending north from its Peruvian center of distribution into Colombia and south to Bolivia (Fig. 81). The species is best recognized by its primarily narrow-elliptic leaves, chiefly five-flowered inflorescence, tube length of ca. 3–4 cm, limb spread of 4–5 cm, and reduced ovule number (generally two per locule, Fig. 89C). Both flower and ovule number have become nearly fixed throughout the range of the species. *Eucharis castelnaeana* is sympatric with *E. ulei* at times but tends to occur on seasonally inundated soils. Flower size and number, ovule number, and chromosome morphology (Meerow, 1987b) suggest close relationship to *E. cyaneosperma*, which has different tube morphology, a deeply trigonous ovary, and blue-coated seeds.

Ravenna (1982: 50) described *Urceolina moana*, citing the "absence of lobes, or teeth, in the cup." The single, poorly preserved, fragmentary flower of the holotype, however, had stamens at least shortly dentate to quadrate. As in *E. candida* and *E. formosa*, androecial toothing in *E. ulei* has little taxonomic significance. The androecial morphology of *E. moana* is well included within the range of variation for this character in *E. ulei* (Fig. 70D)—several collections of *E. ulei* have completely edentate staminal cups (e.g., *Meerow et al. 1024*, *Plowman & Kennedy 5811*, *Prance et al. 13915*). Much the same argument applies to the likewise synonymous *E. boliviensis* (Ravenna, 1988), represented by the only specimen of *E. ulei* collected in Bolivia. The only other collection assigned by Ravenna (1988) to *E. boliviensis* (*Cardenas 1553*) belongs to *E. cyaneosperma*. *Eucharis ipariensis*, inexplicably described by Ravenna (1982) as allied to *E. mastersii* (= *E.* ×*grandiflora* of subg. *Heterocharis*), is also indistinguishable from numerous collections of *E. ulei*.

Kränzlin (1913) and Macbride (1936) noted the dissimilarity of the two specimens comprising the holotype of *E. ulei* (*Ule 5737b*), one in flower, the other in fruit. I have assigned the fruiting specimen (*Ule 5737b*), with blue seeds, to *E. cyaneosperma* Meerow. When a putative isotype of *Ule 5737* was received from MG, it proved to represent *E. castelnaeana*. Ule thus collected three species under a single number, an unsurprising occurrence in areas where several *Eucharis* species are sympatric.

9. Eucharis cyaneosperma Meerow, Sida 12: 29–49. 1987. TYPE: Peru. San Martín: 20 km N of Tocache Nuevo on road to Tarapoto, Río Cañuto, 520 m, 17 July 1982, *Meerow et al. 1032* (holotype, FLAS). Figure 89A.

Bulb subglobose, 3–5 cm long, 3–3.5 cm diam., tunics light brown. Leaves 2–4; petiole (10–)15–30(–35) cm long, 5–6.5 mm thick; lamina (ovate-)elliptic, 18–25(–30) cm long, (6.5–)7–8(–13) cm wide, apically acute to shortly acuminate, attenuate at the base. Scape (3–)4–5(–6.5) dm tall, 5–7 mm diam. proximally, 3–4 mm diam. distally; bracts ovate-lanceolate, (20–)27–35 mm long. Flowers (3–)5(–7), pendent, without fragrance; pedicels (10–)15–25(–28) mm long, ca. 1.7–2 mm diam.; tube 30–40 mm long, 1.5–2 mm diam. for most of its length, dilating abruptly to 7–9 mm proximal to the throat, curved abruptly ca. 5 mm above the ovary and then ± straight; outer tepals 23–28(–32) mm long, 8–10(–13) mm wide, ovate-lanceolate, apiculate; inner tepals 21–24(–30) mm long, 10–14(–15) mm wide, ovate, acute to minutely apiculate. Staminal cup cylindrical, (8–)10–12 mm long (to tooth or lobe), 10–13(–15) mm wide, pale yellow or green proximally, quadrate or irregularly toothed between each free filament, the teeth when present < 1.5 mm long, cleft between each stamen 2–3 mm deep; each stamen 3.5–4(–5) mm wide at the base; the narrow, subulate free filament (3–)3.5–4.5(–5.5) mm long, ca. 1.5 mm wide at the base; anthers ca. 3 mm long, oblong; pollen grain ca. 47.95 μm polar diam., ca. 67.55 μm longest equatorial diam. Style 4.5–6 cm long, exserted 0.5–1 cm beyond the anthers; stigma 2–2.5 mm wide. Ovary subglobose and deeply trigonous at anthesis, 5–7 mm long, 7–10 mm wide, usually wider than long; ovules

2(–3, 5) per locule, superposed in the lower half of the cell. Capsule 10–12 mm long, 15–20 mm wide, bright orange, leathery; pedicel 25–36 mm long; seed ellipsoid, 7–9 mm long, ca. 5 mm wide, with a lustrous, cobalt blue testa. Chromosome number: $2n = 46$.

Distribution. Sporadic in the understory of premontane to lower montane rain forest of the Amazon basin and eastern Andean foothills, from Peru to Bolivia (Fig. 81), 120–800(–1,200) m elevation. Flowering at any time of the year, most commonly in August.

Additional specimens examined. BOLIVIA. EL BENÍ: vicinity of Rurrenabague, 330 m, 25 Nov. 1921, *Cardenas 1179* (AA, NY, US); Rurrenabague, 500 m, 7 Oct. 1921, *Cardenas 1553A* (NY); San Antonio, 15 Nov. 1958, flowered in cultivation 30 Apr. 1959, *Nelson 58-301* (MO); same collection as preceding, flowered in cultivation 4 Apr. 1961, *Nelson 58-301* (MO). BRAZIL. ACRE: basin of Río Purus, near mouth of Río Macauhan, 9°20′S, 69°W, 17 Aug. 1933, *Krukoff 5573* (NY); Río Branco de Obidos, Santo Antonio, 6 Aug. 1912, *Ducke 12162* (GOET, photo and fragment F). MADRE DE DÍOS: Tahuamanu, Iberia, 200 m, 15 Nov. 1973 (fr), *Alfaro 1684* (MO); Iberia, Miraflores, vicinity Río Tahuamanu, 1 Sep. 1945, *Seibert 2145* (US). SAN MARTÍN: (fr), *Schunke 4843* (F, US); Mariscal Cáceres, Tocache Nuevo, Quebrada de Huaguisha (margen derecha del Río Huallaga, 400–450 m, 3 July 1974 (fr), *Schunke 7146* (F). UCAYALI: middle Ucayali, Cashiboplaya, 10°S, 1923, *Tessman 3179* (G, NY, S).

Eucharis cyaneosperma is the only species of *Eucharis* with blue-coated seeds. The species appears very similar to *E. ulei* but differs by having usually shorter leaves, different tube morphology (abruptly curved at the base in *E. cyaneosperma*, sinuously curved in *E. ulei*), irregularly dentate to quadrate staminal cup (Fig. 89A), deeply trigonous ovary, and different seed color. In the southern part of its range, *E. cyaneosperma* occupies more upland sites than are usually characteristic of *E. ulei*.

10. Eucharis lehmannii Regel, Gartenfl. 38: 313–314, t. 1300, fig. 1. 1888. *Urceolina lehmannii* (Regel) Traub, Pl. Life 27: 57–59. 1971. TYPE: Colombia. Cauca: ex hort. Regel, from bulbs collected by Lehmann near Popayan, Apr. 1888, *Regel s.n.* (holotype (fragmentary), LE; photo of holotype, FLAS, K). Figure 90D–F.

Bulb subglobose, not seen. Leaves 2; petiole 45.5 cm long, 3.5 mm thick; lamina ovate-elliptic, 24–25 cm long, 16 cm wide, short acuminate, basally subcordate and attenuate to the petiole. Scape not seen; bracts lanceolate; bracteoles linear-lanceolate. Flowers 4; pedicels to 30 mm long; limb patent, spreading to ca. 4 cm; tube ca. 25 mm long, ca. 1.2 mm wide below, dilating abruptly to 8 mm at the throat; outer tepals 20–22 mm long, 8–10 mm wide, ovate-lanceolate, acute-apiculate; inner tepals 18–20 mm long, 10–12 mm wide, obtuse. Staminal cup 7–8 mm long (to apex of tooth), deeply cleft between each stamen to < 2 mm from the throat; each stamen bidentate, the teeth long-lanceolate, as long as the free filament; free filament linear, 7–8 mm long, ca. 1 mm wide; anthers sub-basifixed, versatile. Style slightly exserted beyond the anthers. Ovary globose-ellipsoid, ca. 6 mm long, ca. 4 mm wide; ovules ca. 10 per locule. Fruit and seed unknown.

Distribution. Extremely rare in the understory of moist, lower montane forest of the Cordillera Oriental in Cauca Department of Colombia (Fig. 91), 1,200 m.

Additional specimen examined. COLOMBIA. CAUCA: Aganche, Río Orejas, 1,200 m, *Lehmann 5883* (K).

Eucharis lehmannii is known only from the fragmentary type (a single flower) and a single specimen at Kew with only one flower present. An Ecuadorean specimen mislabeled as the type of *E. lehmannii*, received from Kew (*Lehmann 7775*), turned out to be *E. astrophiala* (Ravenna) Ravenna. Like *E. caucana*, to which it may be very closely related, *E. lehmannii* is a peripheral isolate of subg. *Eucharis*, with novel androecial character states. Despite the unusual staminal morphology, the plant figured in Regel's (1889) description resembles *Eucharis* subg. *Eucharis* by overall morphology and habit of the flower. In 1984, I was not able to collect this species successfully at the

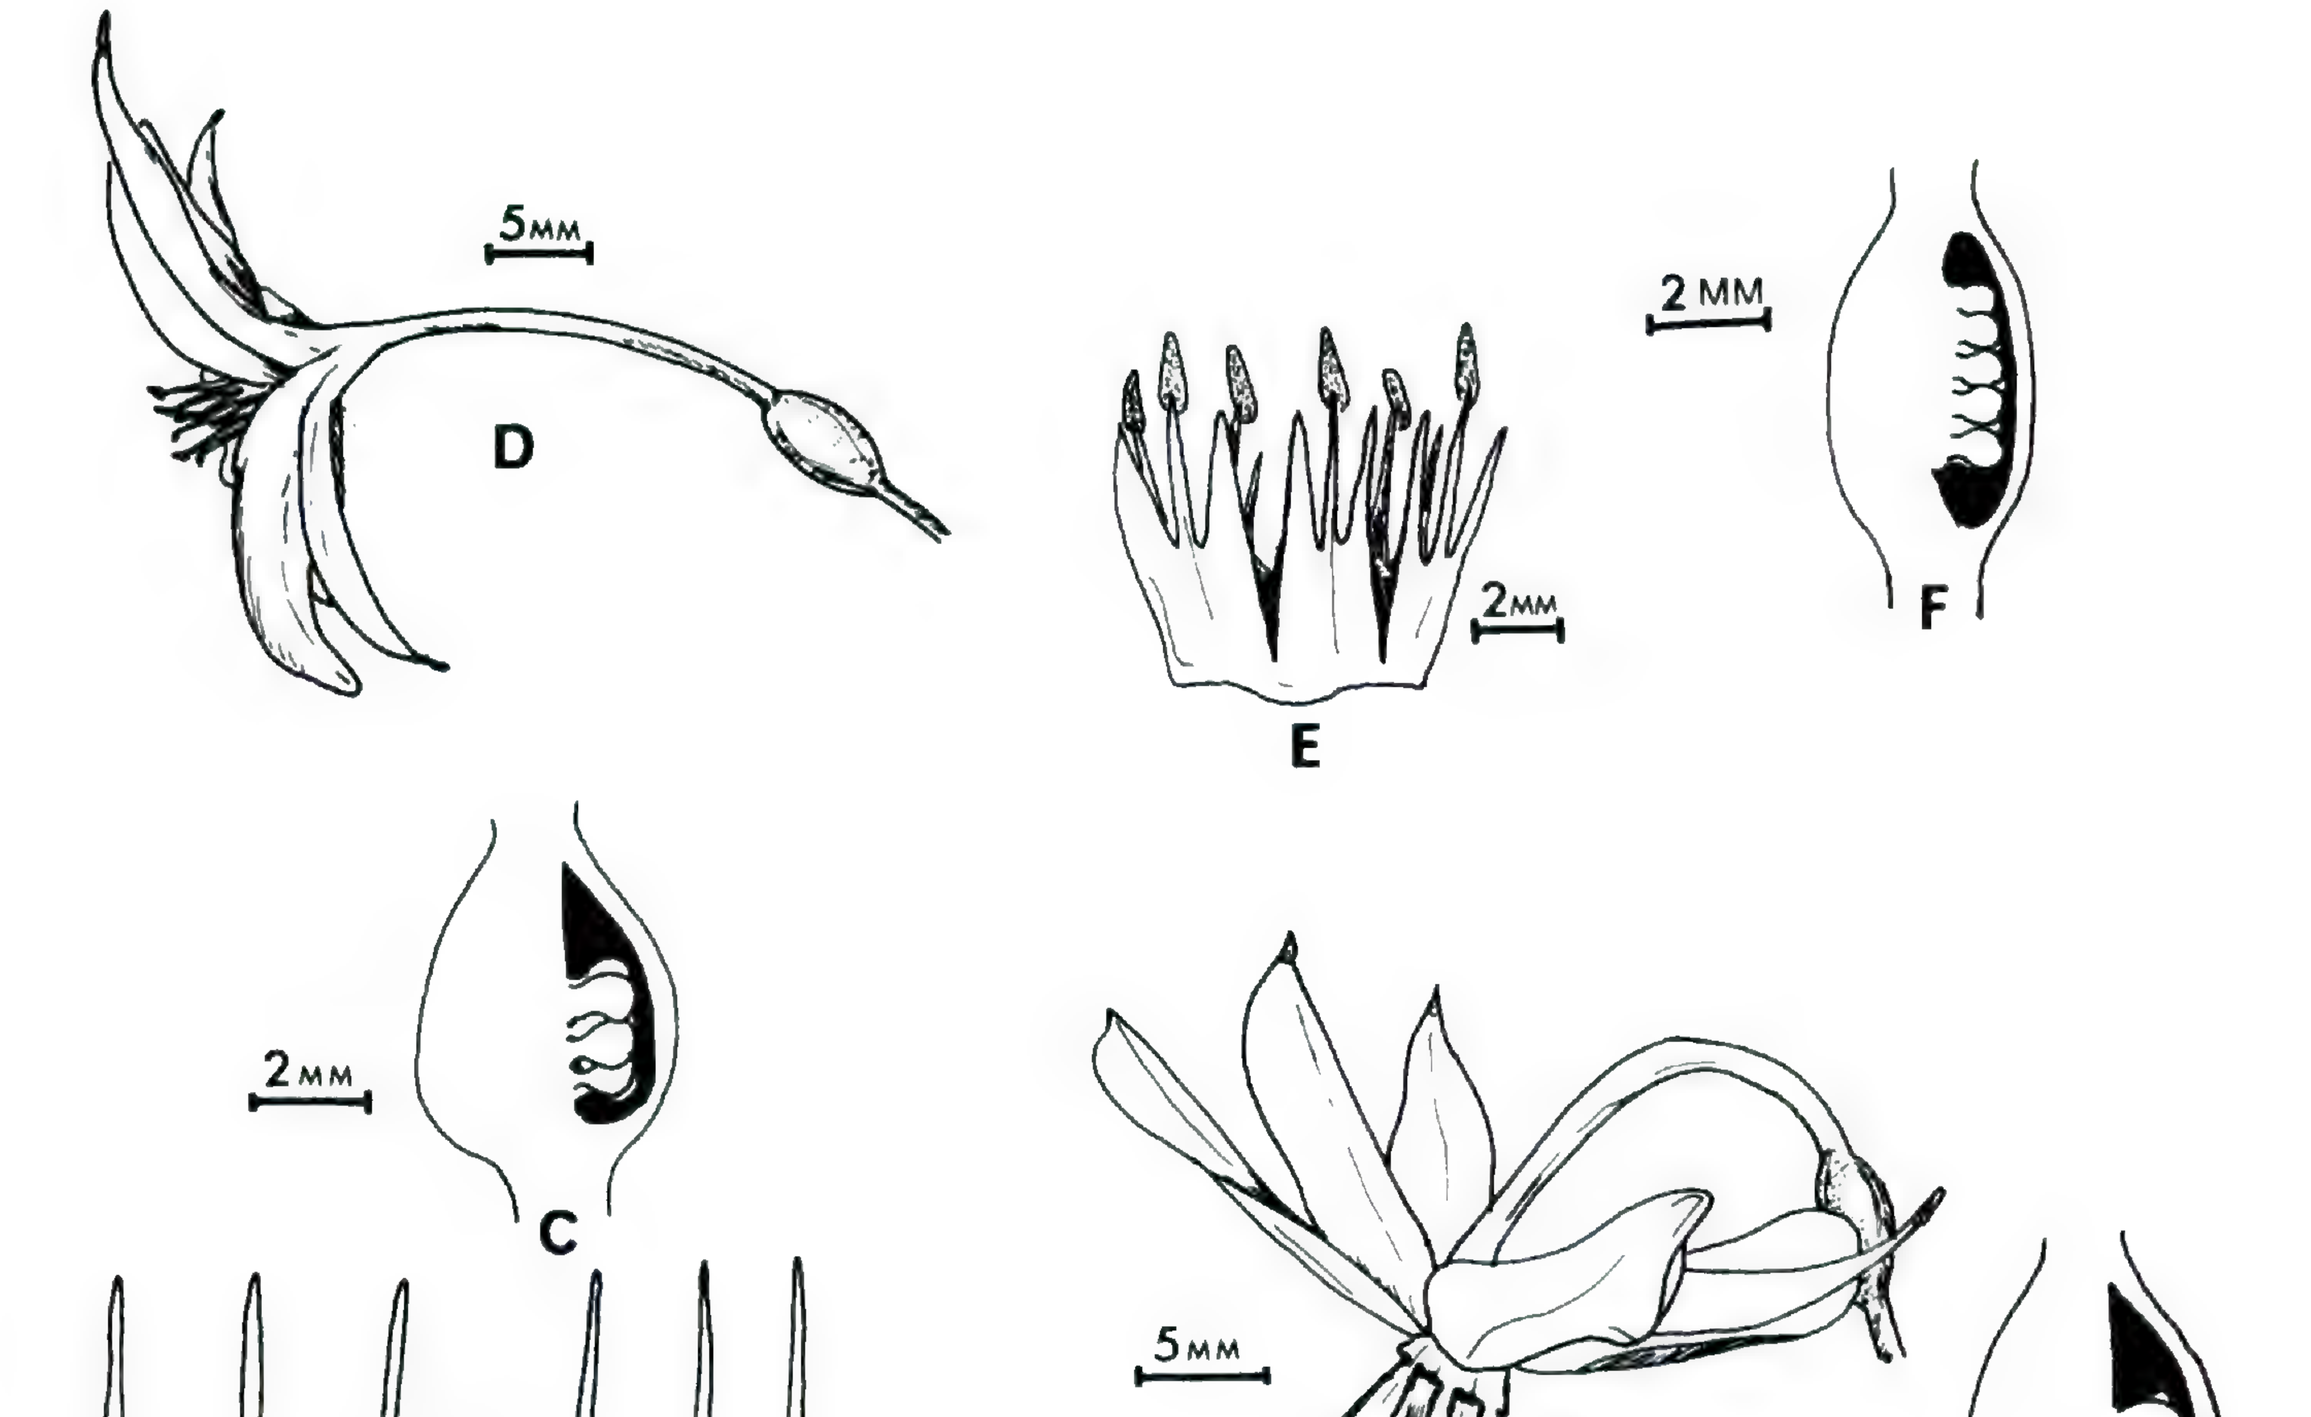

FIGURE 90. *Eucharis corynandra*, *E. lehmannii*, and *E. oxyandra*. A–C. *E. oxyandra* (isotype: *Hutchison et al. 5983*, UC).—A. Flower.—B. Androecium. Note the polymorphism.—C. Ovary, longitudinal section. D–F. *E. lehmannii* (after tab. 1300 in Regel, 1889, and a photo of the type at LE.—D. Flower.—E. Staminal cup.—F. Ovary, longitudinal section. G–I. *E. corynandra* (isotype, *Ravenna 2090*, K).—G. Flower.—H. Staminal cup.—I. Ovary, longitudinal section.

locality of *Lehmann 5883* in Colombia, an area now largely deforested.

11. Eucharis corynandra (Ravenna) Ravenna, Phytologia 57: 95–96. 1985. *Urceolina corynandra* Ravenna, Pl. Life 34: 80–81. 1978. TYPE: Peru. Cajamarca: Chinganza, between Aramango and Montenegro, 2 July 1973, *Ravenna 2090* (holotype, herb, Ravenna, not seen; isotypes, K, not seen: NY, MO). Figure 90G–I.

Bulb globose, 47 mm long, 37 mm diam.; tunics light brown. Leaves elliptic-lanceolate; petiole 25–27 cm long, 3.5–5 mm thick; lamina 20–27 cm long, 5 cm wide, apically acute. Scape 50 cm tall, slender, ca. 2 mm diam. distally; bracts lanceolate, ca. 32 mm long. Flowers 8–10; pedicels 15–23 mm long, thin; perianth tube curved, 17–18 mm long, ca. 1 mm wide for most of its length, abruptly dilated to 3–4 mm at the throat; limb spreading to 3–4 cm wide; outer tepals 27–29 mm long, 6–7 mm wide, ovate-lanceolate, acute-apiculate at the apex; inner tepals ca. 28 mm long, 8–10 mm wide; ovate, acute. Staminal cup short, funnelform, thick and waxy in texture, 3.5 mm long, 7.5 mm wide, with two obtuse teeth between each free filament, somewhat plicate; free filaments club-

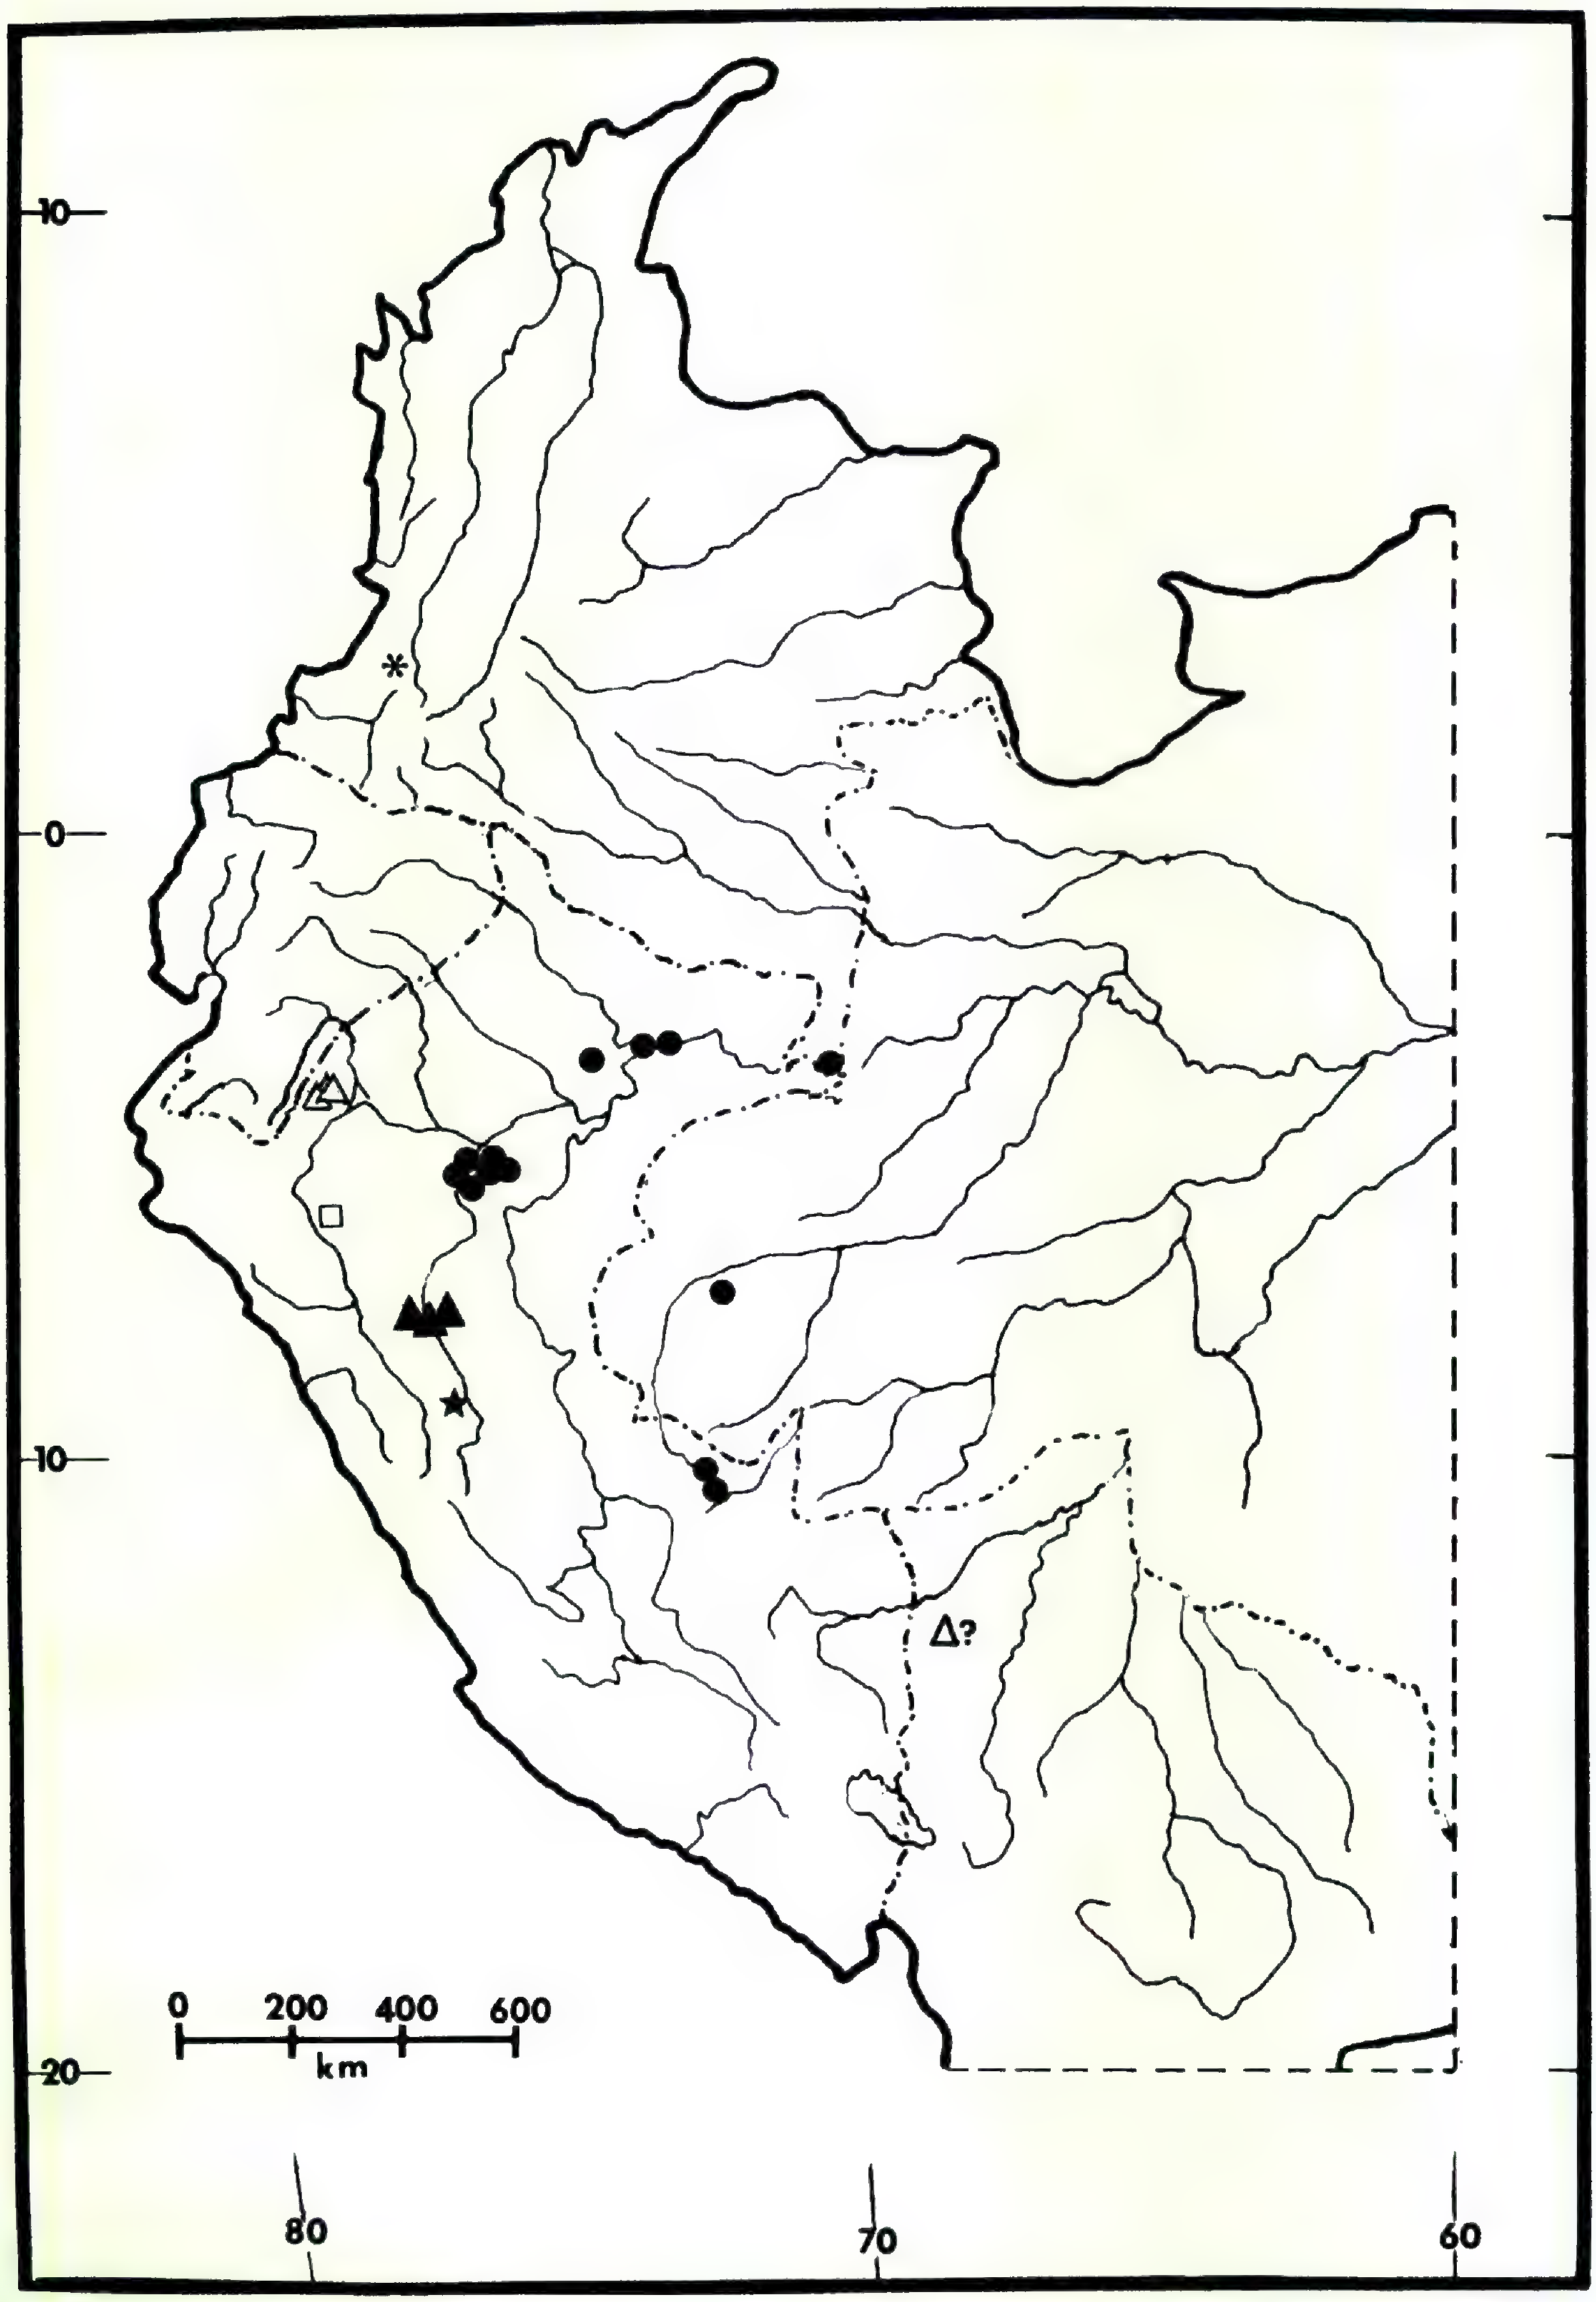

FIGURE 91. Distributions of *Eucharis castelnaeana* (circles), *E. corynandra* (squares), *E. lehmannii* (snowflake), *E. oxyandra* (stars), *E. plicata* subsp. *plicata* (closed triangles), and *E. plicata* subsp. *brevidentata* (open triangles) in northwestern-central South America.

shaped, appearing narrowly elliptic-lanceolate when dry, ca. 6.2 mm long, 1.8 mm wide, abruptly dilated to ca. 1 mm at the base, inserted adaxially between 2 of the teeth; anthers oblong-linear, ca. 3 mm long, versatile, black. Style 30–44.5 mm long, stigma trilobed. Ovary globose-ellipsoid, 6 mm long, 3 mm wide; ovules 4–6 per locule, superposed. Fruit and seed unknown.

Distribution. Known only from the type locality (Fig. 91), in tropical forest on slopes, near a small ravine with *Dieffenbachia* sp., *Heliconia* sp., *Clusia* sp., and *Xyphidium coeruleum* Aubl. Elevation not reported.

In size and number of the flowers, as well as ovule number, *Eucharis corynandra* shows affinity to *E. castelnaeana* (Baillon) Macbr. and to *E. plicata* Meerow. The short staminal cup and distinctive club-shaped free filaments (Fig. 90H) are the principal unique characters of this species. I cannot, however, confirm Ravenna's (1978) description of the anthers as densely pubescent. The collection locality suggests that it is an upland isolate from the Amazonian center of the subgenus, the plant having colonized the lower limits of the "ceja de la selva" forest formations in Cajamarca Department of Peru.

12. Eucharis oxyandra (Ravenna) Ravenna [subg. *Eucharis insertae sedis*], Phytologia 57: 95–96. 1985. *Urceolina oxyandra* Ravenna, Wrightia 7: 251–253. 1983. TYPE: Peru. Huánuco: Huánuco, Río Chinchao, below Carpish on rd. to Tingo Maria, 1,800 m, 19 July 1964, *Hutchison et al. 5983* (specimens prepared from bulbs flowered in cultivation at UC, 26 Apr. 1967) (holotype, USM, not seen; isotypes, MO, UC). Figure 90A–C.

Bulb not seen. Leaves (one seen) elliptic; petiole 17 cm long, 4–6 mm thick; lamina 25 cm long, 12 cm wide. Scape 27–28 cm tall; bracts 34–35 mm long, ovate-lanceolate. Flowers 6–7, (crateriform?), cernuous; pedicels ca. 19 mm long; tube curved, 25 mm long, 1.5 mm diam. below, dilated abruptly at the throat to 3.5 mm; tepals spreading to 27 mm wide; outer series 17–19 mm long, 6.7 mm wide, ovate-lanceolate, acute-apiculate; inner series 17–18 mm long, 8–9 mm wide, ovate, obtuse. Staminal cup very short, 0.8–1.5 mm long, 3–3.5 mm wide, edentate or with 2 obtuse teeth between the free filaments; free filaments ca. 7 mm long, ca. 1 mm wide at the base, narrowly subulate; anthers oblong, 3.3 mm long, sub-basifixed, eventually versatile; pollen grain ca. 42.36 μm polar diam., ca. 68.36 μm longest equatorial diam. Style 32.8 mm long; stigma 2–2.5 mm wide. Ovary globose-ellipsoid, 6 mm long, 4 mm wide; ovules 6–8 per locule. Fruit and seed unknown.

Distribution. *Eucharis oxyandra* is not known in the wild state. The collector's field notes (UC) indicate that three bulbs were found at the type locality (Fig. 91) "exposed on surface of ground with evidence of past cultivation, in deep shade near abandoned hut above road. The third bulb proved to be *Urceolina urceolata* (R. & P.) M. L. Green."

This unusual species has the smallest staminal cup of any Peruvian species of *Eucharis* subg. *Eucharis* (Fig. 90B). The long, almost linear, free filaments are another unusual feature of the androecium. The polymorphism of the staminal cup (both edentate and obtusely dentate forms represented in the isotypes, Fig. 90B) is puzzling and adds further credence to my suggestion that this character has been over-weighted as an indicator of species delimitation in the alpha-taxonomic literature relating to the genus. Alternatively, it is possible that the two bulbs found by the collector and representing this species were of two different origins.

In publishing *Urceolina oxyandra*, Ravenna (1983) was apparently unaware of the unusual situation in which the species was found, having examined only a duplicate at USM, which seems to have lacked the detailed field notes of the collector. He argued that the unusual morphology of the androecium (reduced staminal cup and long, narrowly subulate filaments), similar to that of *Urceolina*, supported the inclusion of *Eucharis* within *Urceolina* (Traub, 1971), a position he recently reversed (Ravenna, 1985). This type of androecial morphology is characteristic of two putative intergeneric hybrids between *Eucharis* and *Urceolina*, ×*Urceocharis edentata* Wright (1910) and ×*U. clibranii* Masters (1892).

Given that the plant was discovered as an artifact of cultivation in company with a bulb of *Urceolina*, and in a geographic area of loose sympatry for the two genera, I thought it possible that *E. oxyandra* might represent a hybrid between *Eucharis* and *Urceolina*. ×*Urceocharis edentata* was supposedly collected in the wild in Peru (Wright, 1910). Pollen of *E. oxyandra*, however, stains 100% with Alexander's (1969) stain. Both ×*U. edentata* and ×*U. clibranii* produced very little pollen (Wright, 1910), an observation confirmed when I examined specimens of both hybrids (ex hort. BM). Pollen grain size of the species is more like that of *Eu-*

charis subg. *Eucharis*, but exine sculpturing resembles that of *Urceolina* (Meerow & Dehgan, 1988). Fertile hybrids between closely related genera are not unknown in Amaryllidaceae (Traub, 1963).

Alternatively, *Eucharis oxyandra* might be a relict taxon close to the ancestor of *Urceolina*, a genus whose divergence from *Eucharis* may have been relatively recent (see previous section). Phylogenetic analysis supports this latter hypothesis. At present, it seems best to treat *E. oxyandra* as a species of *Eucharis*, even though its *known* shared characteristics with *Eucharis* are plesiomorphic, since its phylogenetic relationships are obscured by the large amount of unknown character state data. As in *E. astrophiala*, *E. caucana*, *E. corynandra*, and *E. lehmannii*, this species exhibits a pattern of morphological novelty characteristic of peripheral isolation in *Eucharis*.

13. Eucharis plicata Meerow, Brittonia 36: 18–25. 1984. TYPE: Peru. San Martín: Mariscal Cáceres, Tocache Nuevo, Quebrada de Huaguisha, right bank Río Huallaga opposite Tocache Nuevo, 8°09′S, 76°27′W, 500–600 m, 14 Dec. 1981, *Plowman et al. 11394* (holotype, FLAS; isotypes not seen, F, K, NY, USM).

Bulb subglobose, 5–6 cm long, 4 cm wide, tunics brown. Leaves 2–4 at anthesis, petiole 25–35 cm long; lamina widely elliptic to ovate, (19–)20–30 (–35) cm long, 7–12(–14) cm wide, short acuminate, very shortly attenuate to the petiole, thin, lustrous dark green adaxially, silvery-green abaxially, abaxial cuticle densely striate. Scape 40–60 cm tall; bracts 29–30 mm long, ovate-lanceolate; bracteoles successively shorter and narrower. Flowers (7–)9–10, sometimes lightly fragrant; pedicel suberect, 10–15(–25) mm long; perianth tube 25–28 mm long, 2.5–3 mm wide throughout most of its length, dilating abruptly to 6–10 mm at the throat; limb spreading to 30–40 mm; tepals ovate, recurved at the apex, subequal; outer series ca. 19–24 mm long, 9–14 mm wide, apiculate; inner series 16–23 mm long, 11–15.5 mm wide, apically acute. Staminal cup campanulate, ca. 8.5–12 mm long (to apex of teeth), 10–12(–15) mm wide, apically white, basally pale greenish yellow, plicately folded on either side of the filamental trace, bidentate; each stamen 4.5–5.5 mm wide, the anther-bearing part subulate, 2–3.5 mm long, apically obtuse; anthers oblong-linear, sub-basifixed, erect at first, then becoming versatile, grayish brown, 3.5–4 mm long; pollen grains 41.3–43.5 μm polar diam., 59.9–68.9 μm longest equatorial diam. Style 36–40 mm long; stigma ca. 2.5 mm wide. Ovary globose-ellipsoid, green, ca. 5–6 mm long, 3.4–4 mm wide; ovules 4–8 per locule. Capsule ca. 1 cm long, 2 cm wide, bright orange, leathery; seeds 1–2 per locule, ca. 1 cm long, 5 mm wide; testa shiny black. Chromosome number: $2n = 46$.

KEY TO THE SUBSPECIES OF *EUCHARIS PLICATA*

1a. Flowers not noticeably fragrant; perianth tube dilating to 6–7.5 mm at the throat; staminal cup deeply plicate, ca. 12 mm long to apex of teeth; teeth longer than subulate portion of filament, coarsely serrulate, imbricate; style reaching to half the length of the cup; ovules 7–8 per locule ..... 12a. *E. plicata* subsp. *plicata*

1b. Flowers mildly fragrant; perianth tube dilating to 7.5–10 mm at the throat; staminal cup only shallowly plicate, ca. 8–10 mm long to apex of teeth; teeth shorter than subulate portion of filament, entire, nonimbricate; style reaching to just below the teeth; ovules 4–5(–7) per locule ..... 12b. *E. plicata* subsp. *brevidentata*

12a. E. plicata subsp. **plicata.** Figure 92.

Flowers without noticeable fragrance; pedicel suberect, 10–15 mm long; perianth tube 22–24 mm long, dilating abruptly to 6–7.5 mm wide at the throat; outer tepals 18–23 mm long, 9–12 mm wide; inner tepals 16–20 mm long, 11–12 mm wide. Staminal cup ca. 12 mm long and wide, deeply plicate on either side of the filamental trace; the anther-bearing portion of each filament inserted between 2 irregular, obtuse, coarsely serrulate teeth, each 4–5 mm long, adjacent pairs somewhat imbricate and appearing as one; pollen grain ca. 43.45 μm polar diam., ca. 68.9 μm longest equatorial diam. Style reaching to ½ the length of the staminal cup. Ovules 7–8 per locule.

Distribution. Known only from the type locality, where it is locally abundant (Fig. 91). This population appears to have hybridized with *E. ulei* and contains a range of intermediate morphs in addition to true *E. plicata*. The intermediates show reduced pollen stainability, the presence of nonhomologous chromosomes, and extreme allozyme heterogeneity. It is unclear whether these represent a highly variable F_1, the F_2, or the results of introgression with *E. plicata* subsp. *plicata*. An analysis of this population is in preparation.

Additional specimens examined. PERU. SAN MARTÍN: same locality as the type, 16 July 1982, *Meerow et al. 1025* (FLAS); same locality as the type, 4 Aug. 1974, *Schunke 8046* (F). *Putative hybrids with* E. ulei: PERU.

SAN MARTÍN: same locality as the type, 16 July 1982, *Meerow et al. 1030, 1031* (FLAS).

13b. E. plicata subsp. **brevidentata** Meerow, subsp. nov. TYPE: Bolivia. El Beni [?]: no collection information, ex hort. Fairchild Tropical Garden from collections by Fred Fuchs, Jr., 3 Oct. 1984, *Meerow 1143* (holotype, FLAS).

Subspecies nova differt a subspecies typica dentibus staminalibus brevioribus et non serrulatis vel imbricatis.

Flowers mildly fragrant; perianth tube 25–29 mm long, dilating abruptly to 7.5–10 mm wide at the throat; outer tepals 20–24 mm long, 9–12 mm wide; inner tepals 18.7–23 mm long, 12–15 mm wide. Staminal cup 8–11 mm long (to apex of teeth), 10.5–14 mm wide, only shallowly plicate; teeth ca. 1.5–2 mm long, reaching to about half the length of the subulate portion of the filament, obtuse, entire, nonimbricate; pollen grain ca. 41.3 μm polar diam., ca. 59.9 μm longest equatorial diam. Style reaching to just below the apex of the teeth. Ovules 4–6(–8) per locule.

The epithet of this subspecies refers to the short teeth of the staminal cup.

Distribution. Rare in the understory of premontane and lower montane rain forest of north-central Peru and Bolivia (Fig. 91), 200–420 m. Flowering August–October.

Additional specimens examined. PERU. AMAZONAS: Río Cenepa, vicinity of Huampami, ca. 5 km E of Chavez Valdivía, ca. 78°30′W, 4°30′S, 200–250 m, 11 July 1978 (fr), *Ancuash 1024* (MO); Río Cenepa, 10–12 km NW of Huampami, ca. 420 m, 2 Oct. 1972, *Berlin 148* (NY); Río Cenepa, vicinity of Huampami, ca. 5 km E of Chavez Valdivía, Quebrada Huampami, ca. 78°30′W, 4°30′S, 200–250 m, 15 Aug. 1978, *Kujikat 365* (MO).

Eucharis plicata is phenetically and cladistically closest to *E. castelnaeana*. The phenetic relationship between the two species is most evident in *E. plicata* subsp. *brevidentata*, which in characteristics of the staminal cup and ovule number is intermediate between subsp. *plicata* and *E. castelnaeana*. From the latter, *E. plicata* may be distinguished by its wider leaves and tepals, larger flowers, campanulate staminal cup which is plicate along the filamental traces (Fig. 92E), more numerous ovules, and fruit and seed morphology typical of subg. *Eucharis*.

14. Eucharis castelnaeana (Baillon) Macbride, Publ. Field Mus. Nat. Hist. Bot. Ser. 11: 47. 1931. *Caliphruria castelnaeana* Baillon, Bull. Mens. Soc. Linn. Paris 144: 1133–1136. 1894. *Urceolina castelnaeana* (Baillon) Traub, Pl. Life 27: 57–59. 1971. TYPE: Peru. Ucayali: Pampa del Sacramento, June 1847, *Castelnau s.n.* (holotype, not located; isotype, P). Figure 93.

Eucharis narcissiflora Huber, Bol. Mus. Goeldi Para 4: 543. 1906. *Urceolina narcissiflora* (Huber) Traub, Pl. Life 27: 57–59. 1971. TYPE: Peru. Ucayali: Sarayacu, Catalina, 25 June 1898, *Huber 1574* (holotype, MG; isotype (photo and fragment), F).

Bulb small, subglobose, 2.2–3(–4.5) cm long, 1.4–2.7 cm wide; neck 1–2 cm long, 1–1.5 cm wide; tunics tannish brown. Leaves 2–4; petiole (10–)13–17(–25) cm long, 3–6 cm wide; lamina narrowly ovate-elliptic, (10–)15–20 cm long, 5–7(–10) cm wide, apex shortly acuminate, lustrous dark green adaxially, lighter green abaxially, margins undulate. Scape (2.5–)3–4(–5) dm tall, 5–6 mm diam. proximally, ca. 3 mm diam. distally; bracts (2.5–)3–4 cm long, ovate-lanceolate, greenish white. Flowers (7–)8–10, pendent, small, with a faint lemon fragrance; pedicels 10–18 mm long; tube 15–25(–30) mm long, 1–1.5(–2) mm wide for most of its length, abruptly dilated near the throat to 5–6(–8) mm wide; tepals patent, spreading to (2.5–)3–4 cm, often distally recurved, sometimes strongly reflexed for their entire length; outer tepals (ovate-)lanceolate, 15–20 mm long, 5–7 mm wide, apiculate; inner tepals ovate, 11.5–18.7 mm long, 8–11 mm wide, acute. Staminal cup funnelform-cylindrical to cylindrical, usually subcylindrical proximally and abruptly dilated at ½–⅔ of its length, (5.5–)7–8(–9.5) mm long (to apex of tooth), (7–)9–11(–12) mm wide, zoned greenish yellow in the proximal ⅓–⅔, slightly incurved at the rim, waxy and slightly succulent in texture, bidentate between each free filament, conspicuously plicate between the teeth, very shallowly cleft between each tooth (< 1 mm) and as deep or more deeply cleft beteen the teeth and the free filament (> 1 mm); teeth 0.5–1 mm long, reaching to about half the length of the free filaments, obtuse, entire; free filament subulate, (1.5–)2–3(–4) mm long, ca. 1.5 mm wide at the base, obtuse or acute; anthers 3–4.5 mm long, oblong, grayish brown, sub-basifixed; pollen grain ca. 39.45 μm polar diam., ca. 55.8 μm longest equatorial diam. Style 25–35 mm long, reaching the apex of the cup or slightly inserted; stigma ca. 1.5 mm wide. Ovary globose, 3.5–5 mm diam., white to greenish white; ovules (2–)4–5(–7) per locule. Capsule subglobose, shallowly trilobed, ca. 1 cm long, 1.5 cm wide, glaucous green, thin-walled, sometimes abscising indehiscently; seeds 1–3 per locule, compressed-ellipsoid, ca. 1 cm long, 5 mm wide; testa dull black, rugose. Chromosome number: $2n = 46$.

Distribution. Understory of lowland and premontane, often seasonally inundated, primary rain forest in the Amazon basin, most commonly in Peru, rare in Colombia and Brazil (Fig. 91), 100–200 m. Flowering June–September (–December).

Vernacular names. Amangay, sacha cebolla.

Additional specimens examined. BRAZIL. AMAZONAS: Río Juruá, Río Miry, July 1901, *Ule 5737* in part (MG). COLOMBIA. AMAZONAS: vicinity Leticia, ex hort. Fairchild

Eucharis castelnaeana has been collected most frequently in the vicinity of Yurimaguas in Peru

(Fig. 91) and is sometimes locally abundant in rain forest understory. It has the smallest flowers of any species in subg. *Eucharis* and is the major exception to the correlation of reduced flower size with loss of fragrance that otherwise characterizes *Eucharis*. Several living collections produce a mild lemon scent when ambient temperatures are high (as does *E. plicata* var. *brevidentata*). It is the only species of subg. *Eucharis* in which the ripe capsule is not leathery and orange. The glaucous, green, thin-walled capsule is tardily dehiscent and can abscise without opening, though the seeds within are fully ripe.

Eucharis castelnaeana is autogamous. Under greenhouse cultivation it is the only species of *Eucharis* that successfully sets fruit with self-pollen. Unmanipulated inflorescences regularly set 50–75% of their capsules.

Eucharis castelnaeana is variable in leaf and flower size (Fig. 93A) and, to a lesser extent, in androecial morphology. In his description of *E. narcissiflora*, Huber (1906) made reference to *E. castelnaeana*, described from the same location as Huber's type of *E. narcissiflora*, but differentiated his new species solely on the basis of size. The two taxa represent the extremes of size diversity of a single species and differ by no other characters. Populations represented by *Schunke 14154a* (Fig. 93Ai) have flowers almost twice as large as those of *Schunke 14156* (Fig. 93Aii) but are otherwise indistinguishable. Shape of the staminal cup in the latter collection can range from nearly cylindrical to funnelform-cylindrical.

Eucharis plicata is phenetically the closest species to *E. castelnaeana*. Baillon (1894) considered *E. castelnaeana* intermediate between *Caliphruria* and *Eucharis* in his argument for combining these two genera. Baillon probably weighed flower size heavily in his judgment, one of only two characters by which *E. castelnaeana* resembles *Caliphruria*. In Baillon's time, most other small-flowered *Eucharis* species were not yet described. Additionally, the green, thin-walled capsule of *E. castelnaeana* is like the fruit of *Caliphruria*. Baillon (1894) gave no indication whether he was familiar with the fruit of either *Eucharis* or *Caliphruria*. Nonetheless, perianth and pollen exine morphology place *E. castelnaeana* squarely in *Eucharis* despite its aberrant fruit and seed morphology.

Eucharis subg. **Heterocharis** Meerow, subg. nov.

TYPE SPECIES: *Eucharis* ×*grandiflora* Planchon & Linden, Fl. Serres Jard. Eur. Ser. 1, 9: 255. 1853.

Subgenus *Eucharis* affinis a qua imprimis differt floribus plerumque non pendulis, tubo perianthii bene infra fauce dilato, limbo plerumque minus expanso, ovario grandius et ovulis numerosis en quoque loculo.

Large bulbous perennial herbs. Leaves petiolate, persistent; lamina ovate, thin, plicate or ± smooth between the veins, undulate margined, apically acuminate, subcordate basally and shortly attenuate to the petiole, bright or dark green adaxially, light green abaxially, the abaxial epidermal cells variably striate; petiole subterete. Inflorescence scapose, umbellate, terminated by 2 green ovate-lanceolate bracts. Flowers subsessile or shortly pedicellate, 2–7, white, 7–8 cm long, strongly fragrant, declinate (rarely subpendulous), funnelform-campanulate (rarely crateriform); perianth tube cylindrical to subcylindrical below, abruptly dilated at ⅓–½ of its length, curved, tinged green below; limb of 6 ovate tepals in 2 series, imbricate for half their length, subequal, spreading somewhat above, often slightly undulate. Stamens basally connate into short or long staminal cup partially adnate to the upper portion of the tube, striped green or yellow within along the filamental traces, variously toothed or edentate; distal portion of the filaments linear or subulate, sometimes incurved; anthers linear, versatile at anthesis; pollen grain 40–60 μm (polar axis), 60–76 μm (longest equatorial axis), the exine coarsely reticulate. Style filiform, well-exserted beyond the staminal cup and slightly assurgent; stigma deeply trilobed, often green. Ovary large, ellipsoid, trigonous, appearing rostellate when dry; ovules usually 16–20 per locule, ellipsoid, biseriate. Capsule green, seeds blackish brown with a slightly rugose testa (*E. moorei*).

Three species and two natural hybrids in western Colombia, Ecuador, and rarely Peru.

KEY TO THE SPECIES AND HYBRIDS OF SUBGENUS *HETEROCHARIS*

1a. Leaves deeply plicate; staminal cup reduced to a basal connation of the filaments less than 7 mm long.
  2a. Staminal cup acutely bidentate between each filament, teeth ca. 1.5 mm long ..... 1. *E.* ×*grandiflora*
  2b. Staminal cup edentate or rarely with a single obscure tooth less than 1 mm long at the base of one or several stamens.
    3a. Perianth tube markedly curved, cylindrical for ½–⅔ of its length, then abruptly dilated distally to the throat; free filament somewhat incurved; stigmatic papillae unicellular ... 2. *E. sanderi*
    3b. Perianth tube straight or only slightly cernuous, subcylindrical proximally but distally dilating gradually towards the

throat; free filament straight; stigmatic papillae multicellular ..... 3. ×*Calicharis butcheri*

1b. Leaves shallowly plicate or relatively nonplicate; staminal cup well developed, greater than 1 cm long.

4a. Leaf length-to-width ratio usually equal to or less than 2; perianth more or less campanulate, tepals spreading only 45–60° from the throat; staminal cup acutely bidentate, strongly recurved at the margin; ovules 16–20 per locule; plants of Ecuador, very rare in Peru ..... 4. *E. moorei*

4b. Leaf length-to-width ratio usually greater than 2; perianth crateriform, tepals spreading ca. 90° from the throat; staminal cup obtusely bidentate to quadrate, not strongly recurved at the margin; ovules 9–12 per locule; plants of the Huallaga valley in Peru ..... 5. *E. amazonica*

1. Eucharis ×grandiflora Planchon & Linden, Fl. des Serres Jard. Eur. Ser. 1, 9: 255. 1853. *Urceolina grandiflora* (Planchon & Linden) Traub, Pl. Life 27: 57–59. 1971. LECTOTYPE (Meerow & Dehgan, 1984a): Fl. des Serres Jard. Eur. Ser. 1, 9: pl. 957. Figures 94–96.

Eucharis mastersii Baker, Curtis's Bot. Mag. 111: t. 6831. 1885. *Urceolina mastersii* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: ex hort. Sander (holotype, K; photo, F).

Eucharis lowii Baker, Gard. Chron. 13: 538–539. 1983. *Urceolina lowii* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: ex hort. Low (holotype, K; photo, F).

Bulb 3–5 cm diam., neck 2–4 cm long, tunics light brown. Leaves 1–3; petiole 19–36 mm long, 5–7 mm thick; lamina ovate or elliptic, 20–33 cm long, (10–)13–16 cm wide, apically acuminate, subcordate basally and shortly attenuate to the petiole, deeply plicate, adaxial surface lustrous dark or bright green, abaxial surface light green and densely striate, margins undulate. Scape 4–5 dm tall, 5–6 mm diam., subterete; bracts ovate-lanceolate, green at first, soon marcescent, 2.5–4.8 cm long, 14–17 mm wide. Flowers 2–6, funnelform-campanulate, declinate, sweetly fragrant; pedicel short, 5–7(–10) mm long, 2.5–3.4 mm diam.; tube curved, 40–55 mm long, 1.5–2 mm wide below, dilating at ½–⅓ its length to 20–25 mm at the throat, green in the proximal half, white distally; tepals ovate, imbricate for half their length, white, margins usually undulate, spreading slightly apically; outer series (30–)35–40 mm long, (18–)20–26 mm wide, acute-apiculate; inner series 25–35(–40) mm long, 23–31 mm wide, obtuse. Staminal cup short, 5–7 mm long (to apex of teeth), 23–25 mm wide, stained green or yellow where adnate to the dilated portion of the tube, with 2 acute or obtuse teeth between each stamen, teeth ca. 1.5 mm long; stamens (5–)6.7–7.5(–10) mm wide at the base from tooth to tooth; free filament 7–8.5(–10) mm long, linear or narrowly subulate, 1–1.5 mm wide at the base; anthers oblong-linear, 5.5–6.7(–7.5) mm long, slightly curved; pollen with only 10% stainability. Style filiform, (67–)74–85 mm long, green, assurgent, well exserted beyond the stamens, stigma deeply 3-lobed, 2.5–3.5(–5) mm wide, white or greenish. Ovary oblong, rostellate, 12–19 mm long, 6–8 mm wide; ovules 16–20 per locule, globose, superposed. Fruit and seed unknown, doubtfully ever formed. Chromosome number: $2n = 46$.

Distribution. Rare in the understory of primary and secondary rain forest of southern Chocó and northwestern Valle de Cauca departments of Colombia (Fig. 99), 80–600(–1,000) m elevation, but widely cultivated throughout western Colombia below 1,750 m. Rare and possibly introduced in Ecuador. The plant is functionally sterile. Most collections are from cultivation, and even seemingly native populations may be remnants of cultivation. Flowering at any time of the year.

Additional specimens examined. COLOMBIA. CHOCÓ: entre Istmina y Condoto, Río San Juan y Río Iro, 80–100 m, 5 Aug. 1944, *García-Barriga 11525* (COL, US). VALLE DE CAUCA: Río Cabrera, Tambi, Río Sumapaz, Cundinamarca, 600–1,000 m, Feb. 1883, *Lehmann 2644* (K); Cordova, Río Dagua, *Lehmann 2736* (K in part); Río Teta, Cauca Valley, 1,000 m, *Lehmann 7776* (F, GH, K, NY, US); Cauca, 1,000 m, *Lehmann s.n.* (K); cultivated 50 km SE of Buenaventura on old road to Pacific coast, Río Anchicaya, 500 m, 22 July 1984, *Meerow & Teets 1127* (FLAS). ECUADOR. CARCHI: Chical, path from Juan Maldonado to Tobar Danuso, flowered in cultivation, 23 Dec. 1982, *Madison et al. s.n.* (SEL). Guayas, Guayaquil, cultivated, Nov. 1925, *Mille 40* (QCA). Los Ríos, Hacienda Ana Maria, Canton Vinces, 60 m, *Y. Mexia 6644* (GH, US); vicinity Duran, cultivated, *Rose & Rose 23627* (US). EX HORT.: voucher of *Madison et al. s.n.*, Feb. 1983, *Meerow 1104* (FLAS).

Eucharis ×grandiflora has long been confused with *E. amazonica* Linden ex Planchon (Meerow & Dehgan, 1984a). Meerow & Dehgan (1984a) re-established *E. grandiflora* (without hybrid designation) as distinct from *E. amazonica* in *Eucharis* subg. *Heterocharis*. At the time, I considered *E. lowii* and *E. mastersii* to be distinct but closely related to *E. ×grandiflora*. In 1984, I collected material in Colombia referable to *E. lowii* Baker and received living material of *E. mastersii* collected in Ecuador. According to Baker (1893), who described these two species from cultivated material, *E. lowii* had a staminal cup half as long as

FIGURES 94–98. Natural hybrids of *Eucharis* subg. *Heterocharis*. 94–96. *E.* ×*grandiflora*.—94. Flower of *E.* "*mastersii*" form (*Madison et al. s.n.*, SEL). 95, 96. *E.* "*lowii*" form (*Meerow & Teets 1127*, FLAS).—95. Habit in Colombia.—96. Flower. 97, 98. ×*Calicharis butcheri* (*Meerow 1098*, FLAS).—97. Inflorescences.—98. Flower.

that of *E.* "*grandiflora*," probably referring to *E. amazonica* or *E. moorei* (as *E. grandiflora* var. *moorei* Baker). When I compared the staminal cup of *E. lowii* with that of the lectotype of *E.* ×*grandiflora*, the synonymy of *E. lowii* with *E.* ×*grandiflora* became evident. The two seemed identical in all respects. Baker considered *E. lowii* to be a hybrid of *E. mastersii* and *E.* "*grandiflora*" and *E. mastersii* Baker (1885) to be a hybrid between *E. sanderi* and *E.* "*grandiflora*." Baker distinguished *E. lowii* from *E. mastersii* merely by the former's slightly longer-exserted staminal cup, which does not hold up. I now believe that *E. mastersii* and *E. lowii* are elements of a slightly variable hybrid taxon, *E.* ×*grandiflora*, a putative hybrid of *E. sanderi* and *E. moorei*. Though never collected in western Colombia, *E. moorei* does occur in contiguous northwestern Ecuador. It was likely a collection of this hybrid that Planchon & Linden (1853) described as *E. grandiflora*. *Eucharis* ×*grandiflora* appears intermediate in all respects to *E. moorei* and *E. sanderi*. Virtually all collections of *E.* ×*grandiflora* are from cultivated populations in Colombia and Ecuador according to specimen labels. Pollen stainability of either Colombian or Ecuadorean collections of *E.* ×*grandiflora* is never better than 10%, and I have not succeeded in obtaining seeds in cultivation with either sibling pollen or pollen of other species. The hybrid is slightly variable in leaf morphology, num-

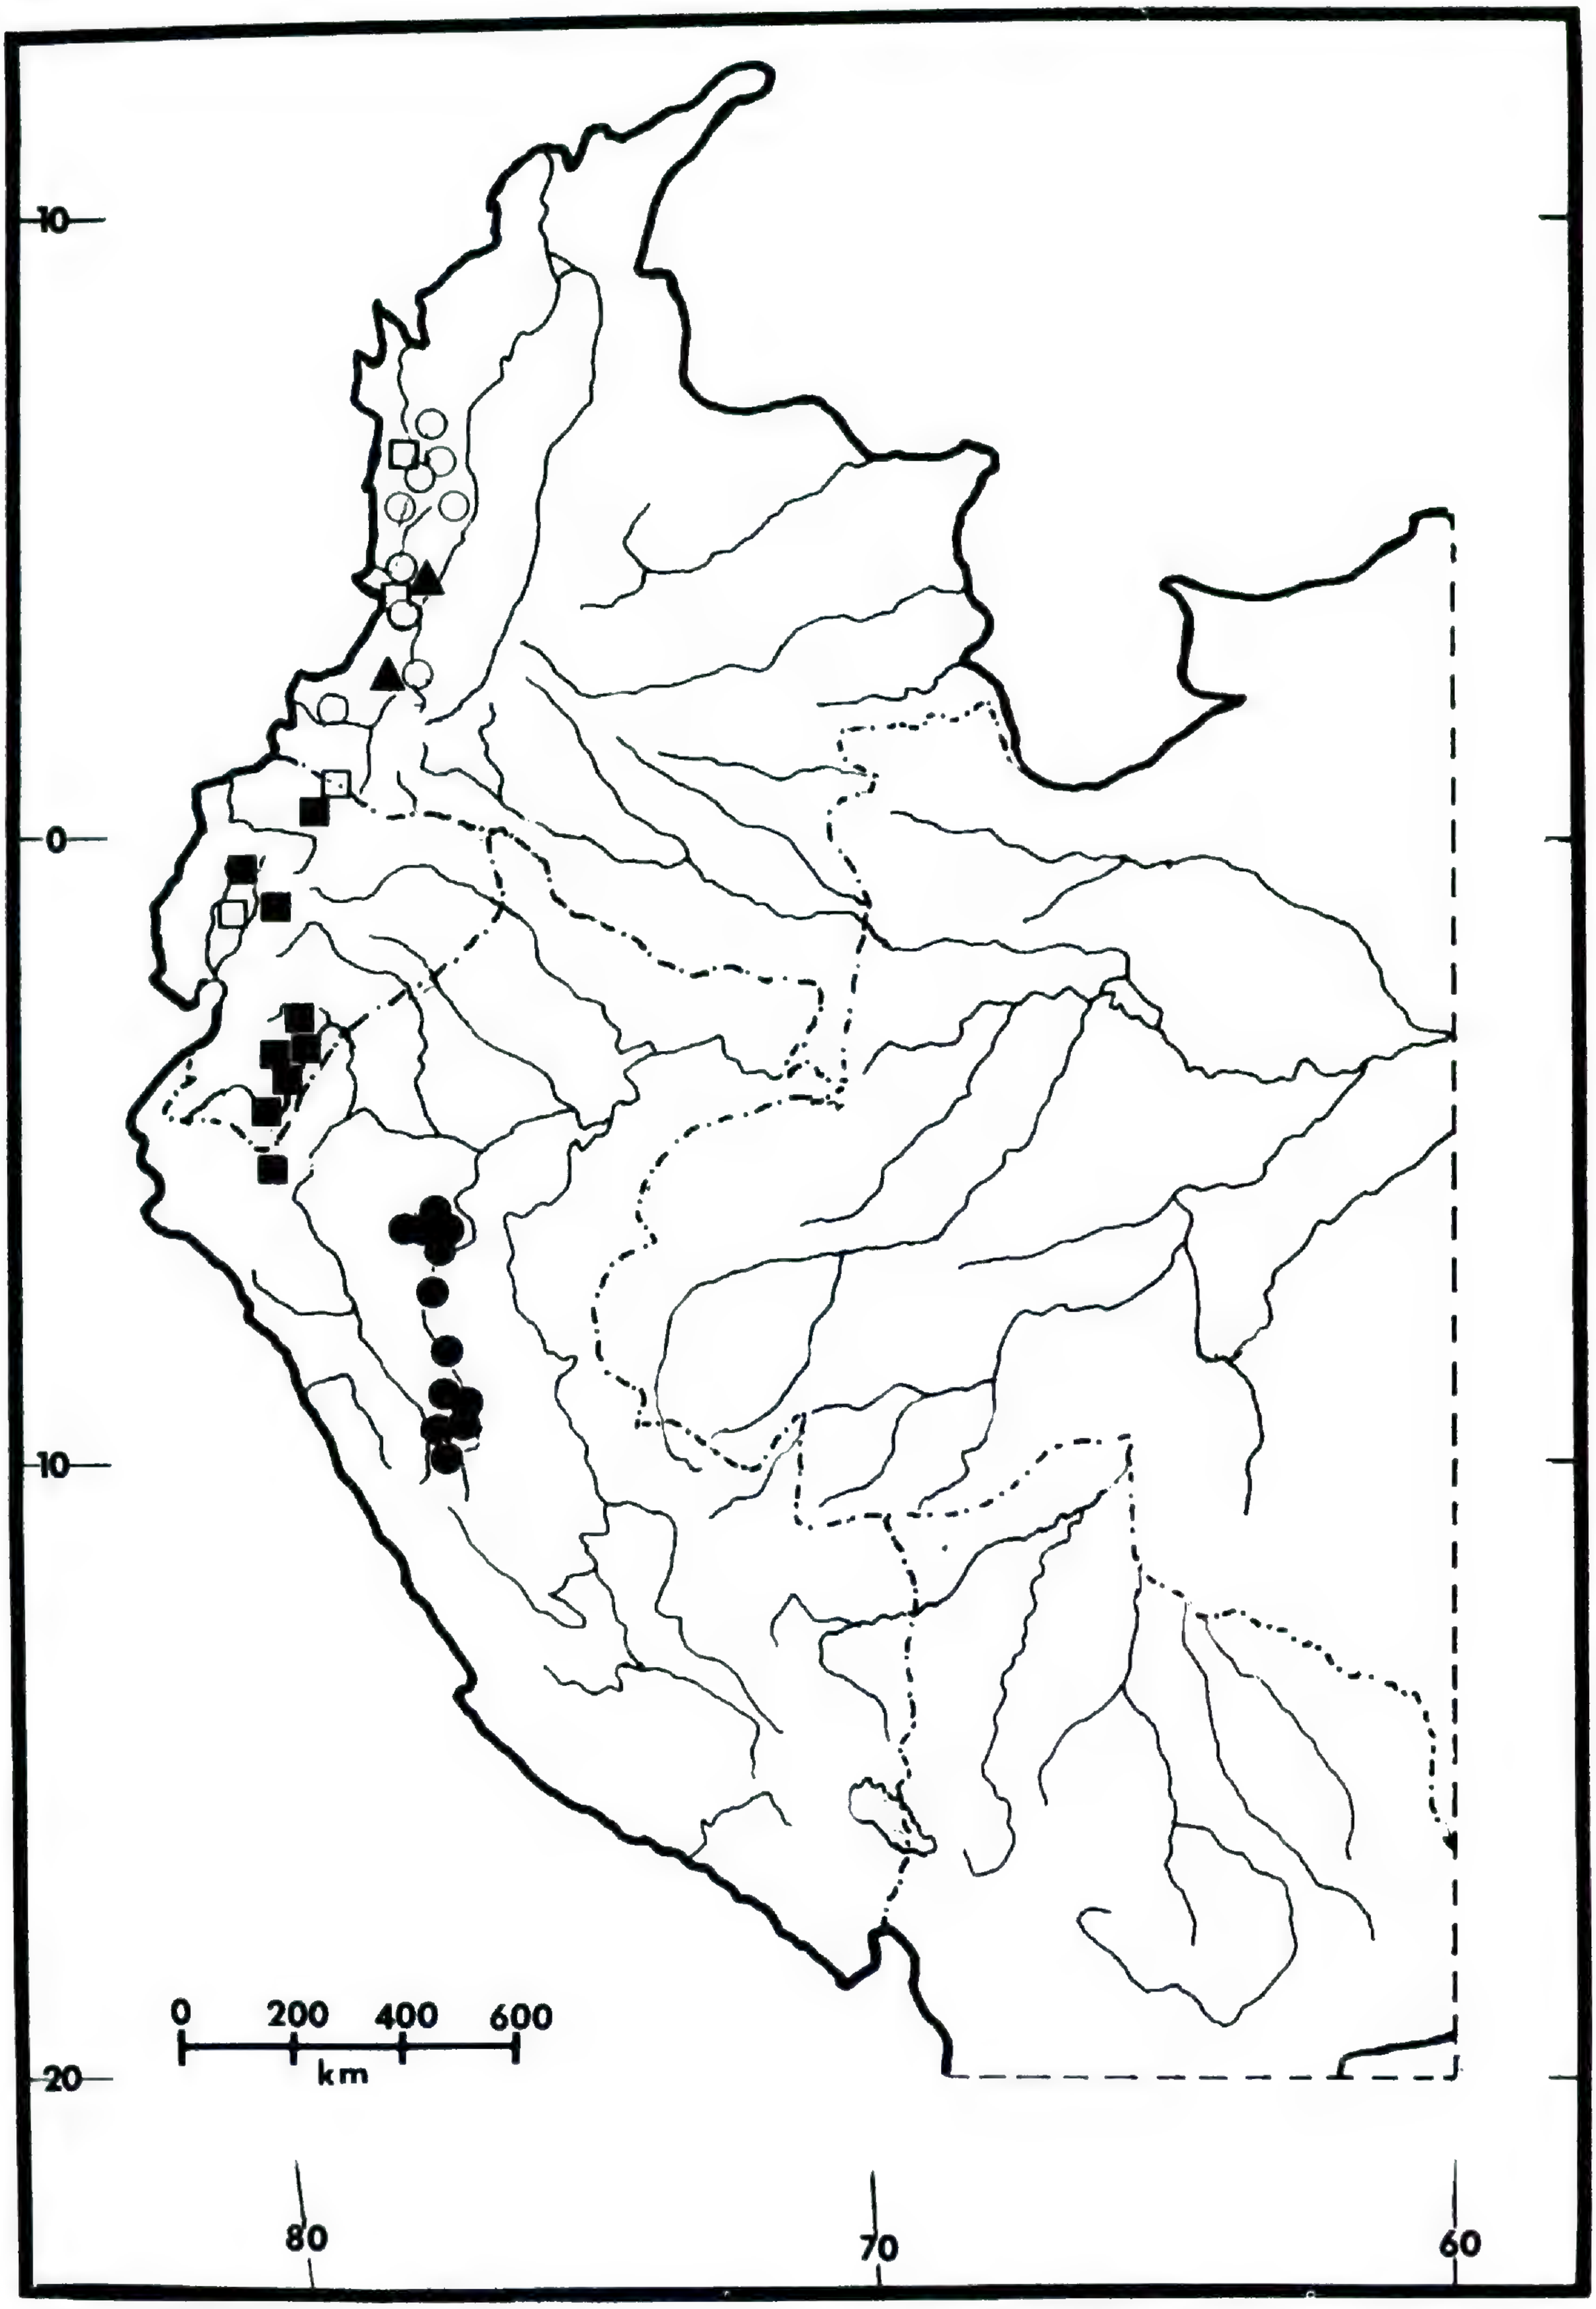

FIGURE 99. Distributions of species and hybrids of *Eucharis* subg. *Heterocharis* in northwestern-central South America. *Eucharis amazonica* (closed circles), *E. sanderi* (open circles), *E. moorei* (closed squares), *E.* ×*grandiflora* (open squares) and ×*Calicharis butcheri* (closed triangles).

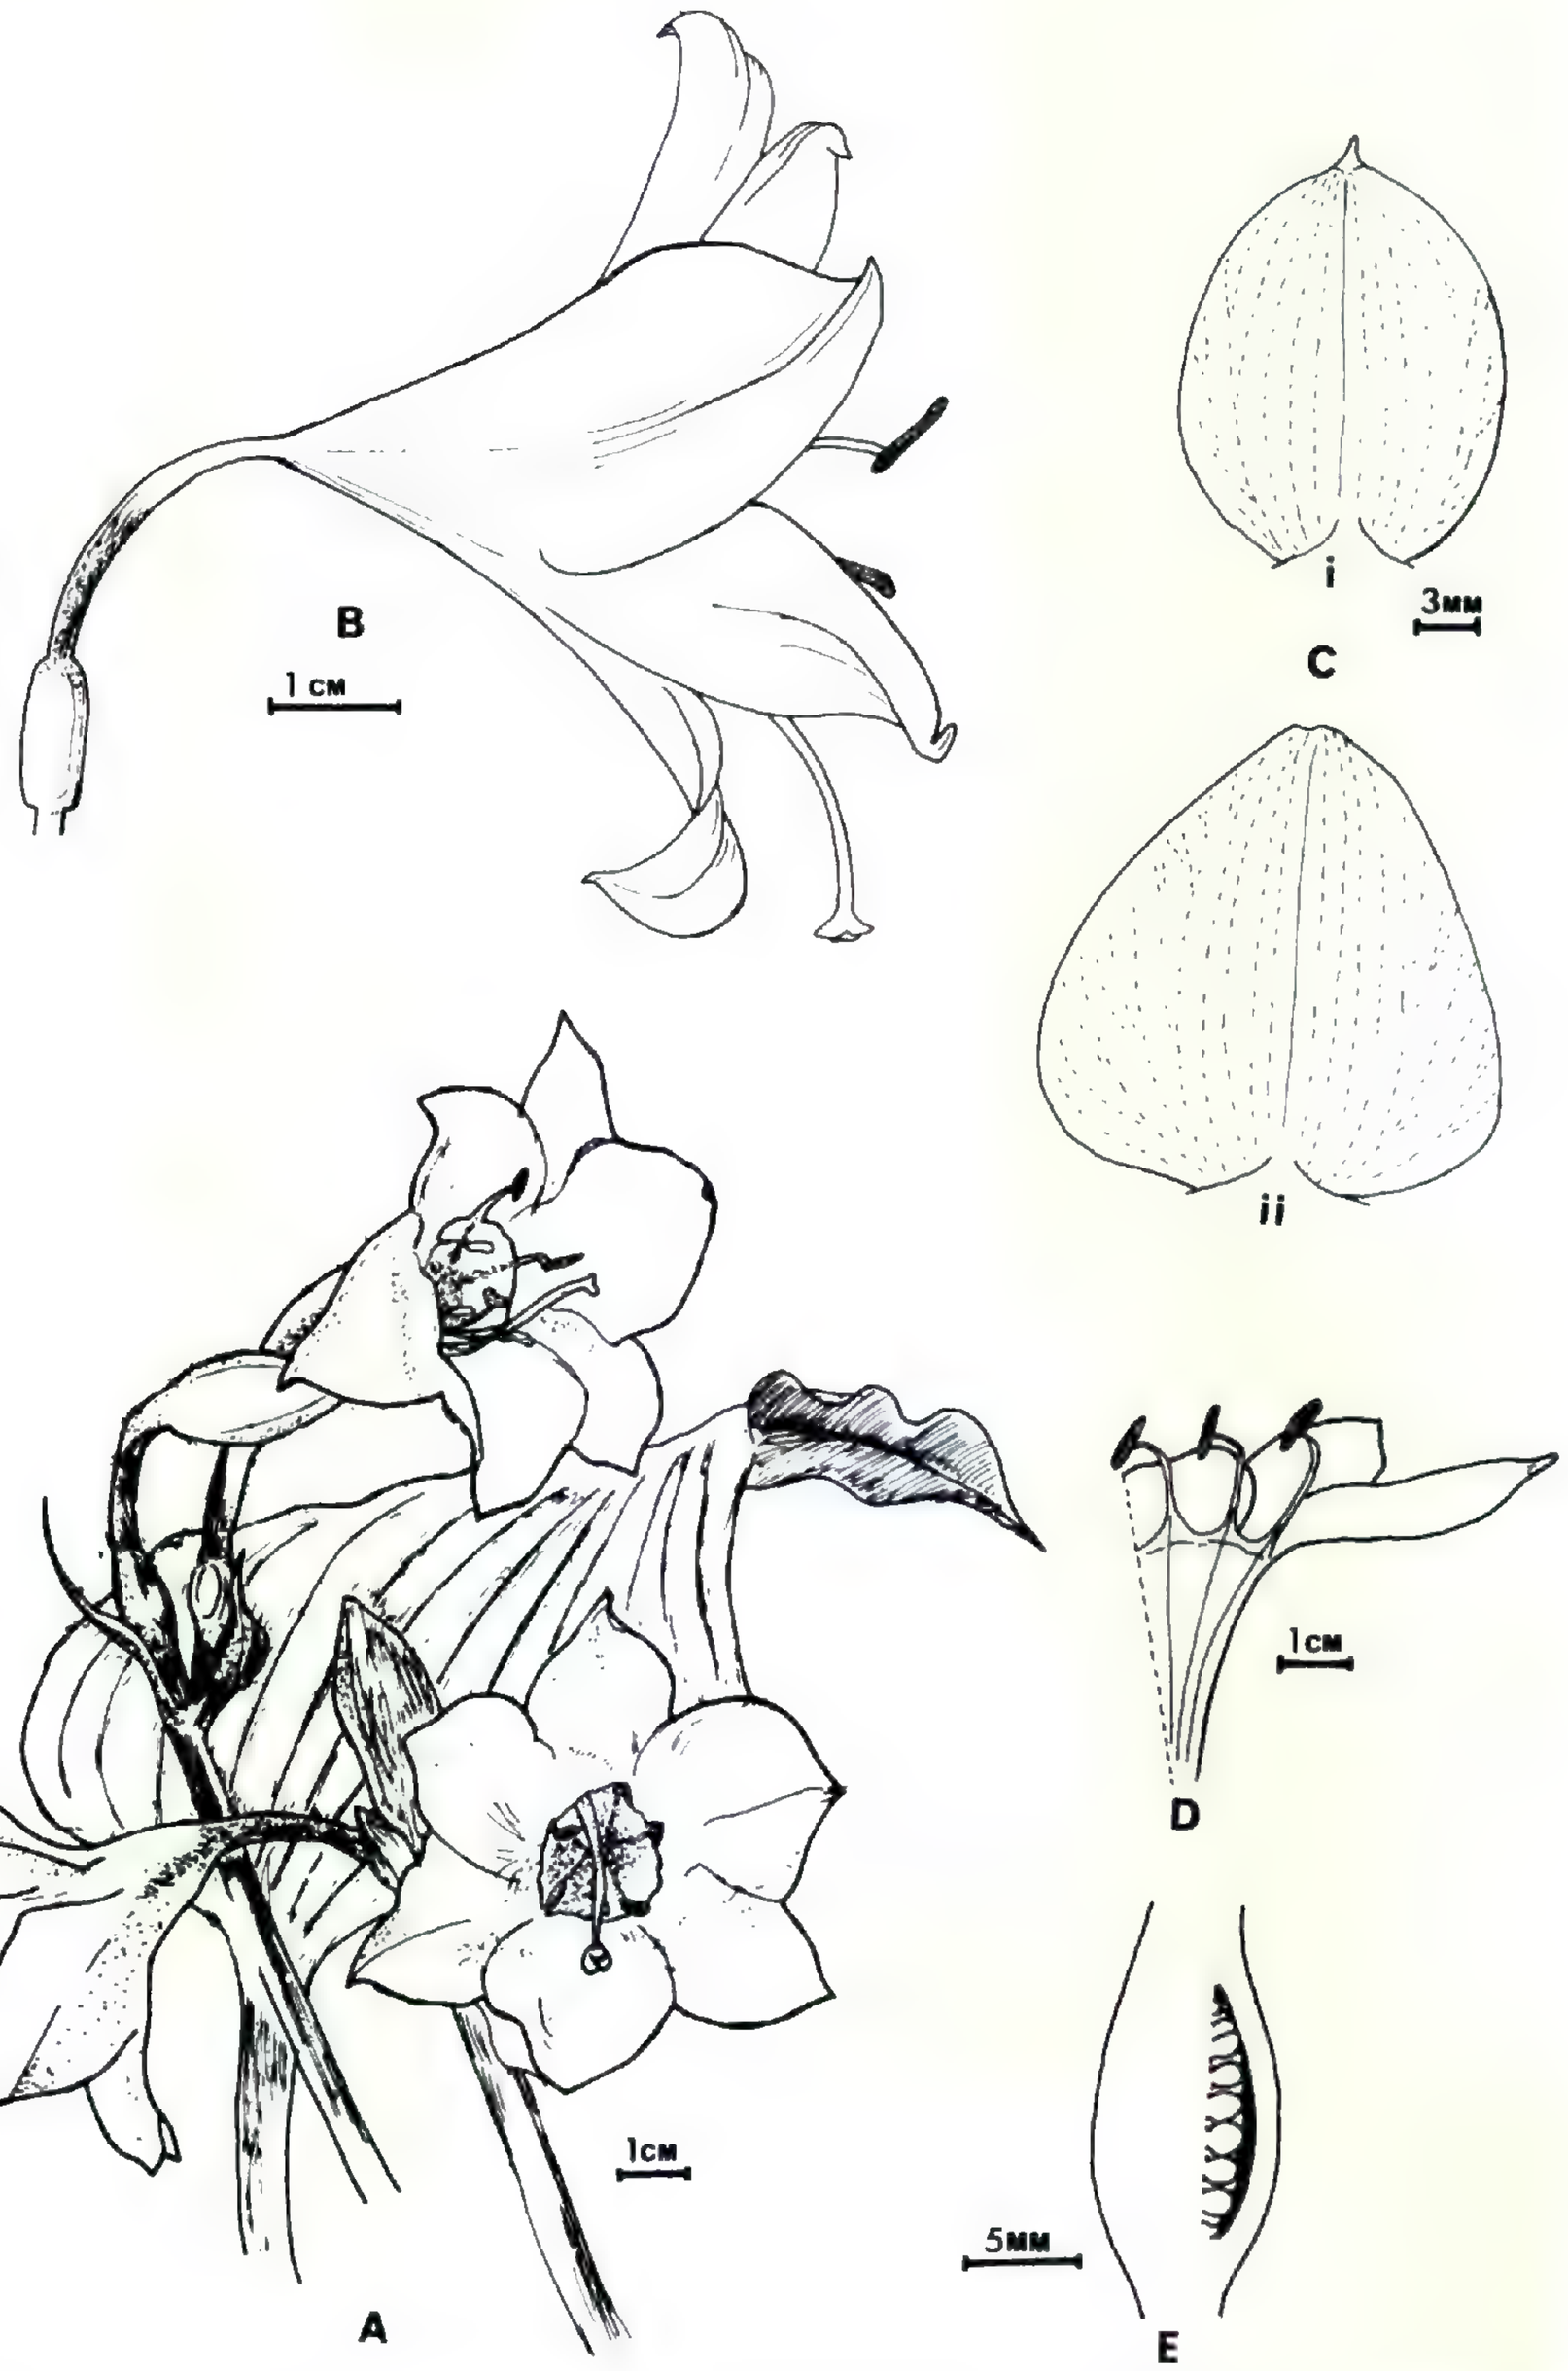

FIGURE 100. *Eucharis sanderi* (*Cuatrecasas 16380*, F). —A. Habit.—B. Flower.—C. Tepals. i, outer tepal; ii, inner tepal.—D. Detail of androecium.—E. Ovary, longitudinal section.

ber of flowers, and color of androecial pigmentation throughout its range, the extremes of which were recognized respectively as *E. mastersii* (Fig. 94) and *E. lowii* (Figs. 95, 96) by Baker (1885, 1893). The labels of all of Lehmann's collections indicate that they were prepared from material in Colombian gardens, and I encountered cultivated material referable to this hybrid in the Cauca valley and Pacific slopes of the Cordillera Occidental.

2. Eucharis sanderi Baker, Curtis's Bot. Mag. 109: t. 6676. 1883. *Urceolina sanderi* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: ex hort. (K). Figure 100.

Bulb 42.5–49 mm long, 32–47 mm wide; neck thick, 24–30 mm wide; tunics light brown. Leaves petiolate, persistent; petiole 31–50 cm long, 5.5–6(–8) mm thick; lamina ovate or elliptic, (23–)30–37 cm long, (10–)14–17 cm wide, thin, deeply plicate between the veins, undulate margined, apically acuminate, subcordate basally and shortly attenuate to the petiole, bright green adaxially, light green abaxially, the abaxial surface intensely striate.

Scape subterete, 45–54 cm long, 5–6 mm diam.; bracts lanceolate, 45–65(–77) mm long. Flowers 2(–3), subsessile (pedicels 5 mm or less long), strongly fragrant, declinate, funnelform-campanulate; perianth tube (45–)50–60(–70) mm long, cylindrical to subcylindrical and 2–3 mm wide below, abruptly dilated at ½ of its length to 20–27 mm wide, curved, tinged green proximally; tepals white, ovate, subequal, imbricate for half their length, spreading somewhat distally; outer series 26–32(–37) mm long, 16–20 mm wide, apiculate; inner series 24–30(–33) mm long, 20–25 mm wide. Stamens basally connate into a short staminal cup partially adnate to the upper portion of the tube, ca. 20–24 mm wide, striped green within along the filamental traces, only shortly exserted beyond the rim of the throat, edentate or rarely with one to few obscure teeth; free filaments (6–)7–9(–9.7) mm long, 1.8–2.2 mm wide at the base, linear, incurved; anthers (5.6–)6–8(–9) mm long linear, versatile, often curved; pollen grain 39.8 μm polar diam., 61.2 μm longest equatorial diam., the exine mostly coarsely reticulate. Style filiform, (66–)75–80(–90) mm long, well exserted beyond the staminal cup and slightly assurgent, white, sometimes flushed green; stigma deeply and obtusely trilobed, (2.8–)3–4 mm wide. Ovary large, ellipsoid, trigonous, appearing rostellate when dry, (10–)15–20 mm long, (5–)7–9(–11) mm wide; ovules (7–)10–20 per locule, ellipsoid, biseriate. Fruit and seed imperfectly known; capsule green; seeds several per locule.

Distribution. Endemic to western Colombia locally on sites with rich soil in the understory of wet, lowland rain forest, primarily in Chocó department (Fig. 99), frequently along watercourses; occasional in similar habitats in Valle de Cauca Dept., (5–)30–300(–1,000) m. Flowering may occur at any time of the year.

Additional specimens examined. COLOMBIA. CHOCÓ: headwaters of Río Tutunendo, E of Quibdo, 20–21 May 1931, *Archer 2197* (US); Municipio de San José del Palmar, Río Torito, 630–830 m, 5 Mar. 1980, *Forero et al. 6728* (MO); Río San Juan between Dipurdu & San Miguel, ca. 100 m, 14 Aug. 1976, *Gentry & Fallon 17687* (MO); Taparalito, Quebrada Taparal, N of Palestina, 4°15′N, 77°12′W, 30 m, 30 Mar. 1986, *Gentry et al. 53784* (FTG, MO); Corcovada region, upper Río San Juan, Yeracüi valley, 200–275 m, 24–25 Apr. 1939, *Killip 35276* (US); Andagoya, 70–100 m, Apr. 1939, *Killip 35401* (US). VALLE DE CAUCA: Río Calima, La Trojita, 5–50 m, 19 Feb.–10 Mar. 1944, *Cuatrecasas 16380* (F); Río Calima, Quebrada de La Brea, 30–50 m, 18–22 May 1946, *Cuatrecasas 21195* (F); Río Telembi, 12 Aug. 1880, *Lehmann 65* (G); Río Dagua, 0–300 m, 11 Aug. 1884, *Lehmann s.n.* (G). CAUCA: El Tambo, La Costa, 1,000 m, 3 July 1935, *von Sneidern 404* (S); El Tambo, 800 m, 7 July 1936, *von Sneidern 1129* (S). CALDAS: Riseralda [?], Tatáma, Santa Cecilia [La Celia?], 800 m, 1 Dec. 1945, *von Sneidern 5208* (S).

This species is characterized by its large, sweetly fragrant funnelform-campanulate flowers, large ovaries and capsules, and reduced staminal cups. "Natural" hybrids exist between *E. sanderi* and both *E.* "*moorei*" (*E.* ×*grandiflora*) and "*Caliphruria subedentata*" (×*Calicharis butcheri*). Despite the many putatively primitive characteristics of *E. sanderi* (e.g., large flowers, strong fragrance) in common with *E. moorei*, ovule number of *E. sanderi* is highly variable, and its leaves are deeply plicate. The reduced morphology of the androecium is the major advanced character of *E. sanderi*.

3. ×Calicharis butcheri (Traub) Meerow, Nothogen. et comb. nov. *Eucharis butcheri* Traub, Pl. Life 23: 68. 1967. *Urceolina butcheri* (Traub) Traub, Pl. Life 27: 57–59. 1971. TYPE: ex hort. Traub, purported to have been collected in Panama by J. N. Giridlian, *Traub 1051* (holotype, MO). Figures 97, 98.

Eucharis sanderi Baker var. *multiflora* Baker, Curtis's Bot. Mag. 111: t. 6831. 1885. *Eucharis sanderi* Baker subsp. *multiflora* (Baker) Traub, Pl. Life 23: 65. *Urceolina sanderi* subsp. *multiflora* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: Colombia. No other data, *Lehmann s.n.* (holotype, K).

Bulb 6–7 cm long, 3.8–5 cm wide, neck short and thick, tunics brown. Leaves 2–3; petiole 20–40 cm long, 5–6 mm wide; lamina elliptic, 21–26(–35) cm long, (10.5–)12–15 cm wide, shortly acuminate, subcordate-attenuate at the base, conspicuously plicate, adaxial surface bright to dark green, abaxial surface lighter green, the cuticle intensely striate. Scape 5–6 dm long, 4–5.5 mm diam.; primary bracts lanceolate, 41–57 mm long. Flowers 4–6(–7), funnelform-campanulate, fragrant; pedicels 4.5–5(–8) mm long; tube 35–42 mm long, funnelform proximally, dilating gradually from 1.5 mm wide at the base to 3.5 mm wide at median length, then abruptly dilated in the distal half to 13–16 mm wide at the throat, green for most of its length, the interior of the dilated portion stained green, most prominently along the filamental traces; tepals white, imbricate for half their length, spreading eventually to 45–55(–60) mm wide, margins nonundulate; outer series 20–28 (–35) mm long, 12–17.5 mm wide, acute-apiculate; inner series 19–27(–32) mm long, 18–25 mm wide, obtuse. Stamens shortly connate below, edentate or rarely with one obscure tooth between some of the filaments, white; free filament linear,

straight or slightly curved apically, 6.7–8.7 mm long, 0.6–1 mm wide at the base where abruptly dilated to 2.5–3 mm; anthers (4.5–)6 mm long, linear-oblong, grayish brown, mostly devoid of pollen. Style 6–7 cm long, overtopping the stamens, slightly assurgent, white distally, green proximally; stigma obtusely trilobed, (2–)2.8–3 mm wide, papillae multicellular. Ovary globose-ellipsoid, 7.7–12(–15) mm long, (5–)7–9 mm wide; ovules 7–10(–12) per locule. Fruit and seed unknown, doubtfully ever formed. Chromosome number: $2n = 46$.

Distribution. Rare in western Colombia (Fig. 99), along the Río Dagua in Valle de Cauca Department, and the lower Cauca valley.

Additional specimens examined. COLOMBIA. VALLE DE CAUCA: Río Dagua, 17 Mar. 1883, *Lehmann 2736* (BM, K); Río Dagua, 200–500 m, *Lehmann 7774* (F, K in part). CAUCA: El Tambo, La Costa, 1,000 m, 24 June 1936, *Von Sneidern 1269* (S). PROVENANCE UNKNOWN: no data, Jan. 1938, *Cuatrecasas 1620* (F). EX HORT.: Kew acc. 430.53.43001, June 1984, *Meerow 1110* (FLAS).

This putative hybrid between *E. sanderi* and *Caliphruria subedentata* was first described by Baker (1885) as *Eucharis sanderi* var. *multiflora*. It has been collected in the wild at the interface of the distributions of both parents and at intermediate elevations. The plant produces little pollen, none of it staining with Alexander's (1969) stain. Floral morphology is intermediate between both parents, although, like *C. subedentata*, the stigmatic papillae are multicellular. There is some karyological evidence of hybrid intermediacy as well (Meerow, 1987b).

4. Eucharis moorei (Baker) Meerow, Sida 13: 29–49. 1987. *Eucharis grandiflora* var. *moorei* Baker, Gard. Chron. 4: 628. 1888. TYPE: ex hort., 1888, *Glasnevin s.n.* (K). Figures 101, 102.

Bulb 6–7 cm long, 2.5–4 cm diam., tunics brown. Leaves 2–3; petiole 2–4 dm long, 5–7 mm thick, with an anomalous arc of accessory vascular bundles near the adaxial surface; lamina broadly ovate, length/width ratio ≤ 2, 17–30 cm long, 10–14 cm wide, apex shortly acuminate, base appearing cordate at the base, margins coarsely undulate, lustrous dark green adaxially, lighter green abaxially, abaxial cuticle mostly without striations. Scape 5–7 dm tall, terete, 7–10 mm diam. proximally, ca. 5 mm diam. distally; bracts ovate-lanceolate, (25–)35–45 mm long, green. Flowers usually 4, rarely up to 7, ± campanulate, declinate, sweetly fragrant; pedicels usually short, 3–10(–18) mm long; tube 40–52 mm long, cylindrical and 1.7–2 mm wide proximally, abruptly dilating at about its midpoint to (15.5–)18.5–25 mm at the throat, white except for a slight green tinge at the base; limb spreading less than 90° from the throat to ca. 70 mm wide or less; tepals ovate, the margins undulate; outer series 3.3–4 cm long; 17–22 mm wide, apiculate; inner series 2.9–3.8 cm long, 22–27 mm wide, obtuse. Staminal cup broadly cylindrical, (8–)10–15(–16.4) mm long (to apex of teeth), 20–25 mm wide, strongly recurved at the margins, white on the exterior, yellowish green on the interior, shallowly cleft between each stamen, bidentate between each free filament, teeth acute, 2.5–3 mm long; each stamen ca. 7–8 mm wide tooth to tooth; free filament subulate, (5–)6–8.5 mm long, 2 mm or less wide at the base; anthers 5.5–6.5 mm long, oblong-linear, grayish-brown; pollen grain ca. 48.6 μm polar diam., ca. 71.2 μm longest equatorial diam. Style 6–7 cm long; stigma 2.5–3.5 mm wide, white. Ovary ellipsoid-trigonous, (7–)10–13 mm long, ca. 5 mm wide; ovules 16–20, biseriate. Capsule globose, ca. 1.5 cm long, 1.3 cm wide, slightly rostellate, green, slightly glaucous; seeds 1–3 per locule, compressed globose, ca. 6 mm diam., turgid, testa blackish brown and slightly rugose. Chromosome number: $2n = 46$.

Distribution. An understory plant of primary and secondary lower montane rain forest of the Ecuadorean Andes (Fig. 99), in Morona-Santiago and Zamora-Chinchipe provinces on the east slopes, and Los Ríos, Cotopaxi, and contiguous Pichincha provinces on the western declivity, (220–)600–1,200(–1,600) m; rare in the "ceja de la selva" of Cajamarca Department, Peru. Flowering is concentrated January–March and again (June–) July–September.

Additional specimens examined. ECUADOR. COTOPAXI: km 52–53 on rd. from Quevedo to Latacunga, Río Pílalo, 800–950 m, 11 Aug. 1984, *Meerow & Meerow 1137* (FLAS); same locality, 13 Aug. 1984, *Meerow & Meerow 1141* (FLAS). GUAYAS: Guayaquil, cultivated, Nov. 1926, *Mille 40* (QCA). LOS RÍOS: km 56 Quevedo–Santo Domingo, Río Palenque Biological Station, 220 m, flowered in cultivation, *Dodson 5527* (SEL); same locality, 16 Oct. 1984, *Dodson & Dodson 15330* (MO). MORONA-SANTIAGO: 27 km SE of San Juan Bosco, 1,270 m, 27 Jan. 1981, *Gentry et al. 30913* (MO, SEL); Indanza-Limón (General Plaza), 1,300–1,600 m, 23 Mar. 1974, *Harling & Andersson 12779* (GB); 3 km N of Tucumbatza on road Gualaquiza–Indanza, 1,200 m, forest remnants, 19 Apr. 1985, *Harling & Andersson 24329* (GB); Río Yunganza, rd. FIGURE 101. *Eucharis moorei*, after a drawing by Wendy B. Zomleffer of *Dodson 5527* (SEL).—A. Habit.—B. Flower.—C. Ovary, longitudinal section.

(K); 10–20 km from Gualaquiza on rd. to Sigsig-Cuenca, 1,300 m, 5 Aug. 1984, *Meerow & Meerow 1135* (FLAS). PICHINCHA: Nanegal, W slope Andes, 5,000 ft., *Jameson 9* (G, P). ZAMORA-CHINCHIPE: Yurupaza, 600 m, 3 June 1947, *Harling 1407* (GB); W side Río Valladolid, 2,100–2,400 m, 15 Oct. 1943, *Steyermark 54717* (F). PERU. CAJAMARCA: Jaen, Río Tabaconas valley, 900–1,000 m, May 1912, *Weberbauer 6251* (GH, US).

Herbarium material of *E. moorei*, when first received, was assigned to *E. amazonica*. In 1984, I collected the species on both sides of the Ecuadorean Andes. Morphological, anatomical, and karyological differences between these collections and the Peruvian *E. amazonica* became evident. *Eucharis moorei* is fully fertile, diploid ($2n = 46$), and of fairly wide distribution throughout Ecuador. The anomalous arc of secondary bundles that appear in petiolar transverse sections of *E. moorei*, and reduced, in *E. amazonica*, are not found in

any other species of the genus investigated. *Eucharis moorei* is putatively the most primitive species of the genus, and shares numerous plesiomorphic character states with other genera of "infrafamily" Pancratioidinae (e.g., large fragrant flower, short pedicels, and numerous ovules per locule). *Eucharis moorei* is the only species in the genus that occurs on both sides of the cordillera.

5. Eucharis amazonica Linden ex Planchon, Fl. des Serres Jard. Eur. Ser. 2, 2: 1216–1217. 1857. LECTOTYPE (Meerow & Dehgan, 1984a): Fl. des Serres Jard. Eur. Ser. 2, 2: t. 1216–1217. Figure 103.

Bulb 3.5–6 cm diam., neck 2.8–4.5 cm long, tunics brown. Leaves usually 2–4; petiole (15–)25–30(–50) cm long, 5.5–9 mm thick; lamina long-elliptic, (20–)30–40(–50) cm long, (10–)12–18 cm wide, length/width ratio usually greater than 2, acuminate, subcordate at the base and attenuate to the petiole, lustrous, dark green adaxially and shallowly or inconspicuously plicate, abaxial surface lighter green, cuticular striations obscure or largely absent, margins coarsely undulate. Scape 4.5–7(–8) dm tall, ca. 1–1.5 cm diam. proximally, ca. 5 mm diam. distally, terete; primary bracts (30–)35–58(–61) mm long, broadly ovate-lanceolate, green. Flowers (4–)5–6(–8), subpendulous, sweetly fragrant; pedicel (9–)10–15(–25) mm long; tube white throughout, curved, (41–)46–58 mm long, cylindrical below and 2–2.5 mm wide, dilating abruptly at ⅓ length to (15–)18–21(–24) mm at the throat; limb white, spreading widely to 60–90 mm wide; tepals ovate, outer series 35–45(–50) mm long, 21–30 mm wide, apiculate; inner series 30–40(–45) mm long, 25–35 mm wide, acute. Staminal cup widely cylindrical, 11.2–13.8 mm long (to apex of teeth), (22–)28–30(–34) mm wide, margins slightly recurved, the interior stained green, particularly along the filamental traces, shallowly cleft between each stamen; stamens 7–8(–9.5) mm wide at the base, each with 2 obtuse teeth, one on each side of the subulate free filament, rarely subquadrate; teeth 2–3 mm long; free filament 6.5–8(–10) mm long, 2.8–3.4 mm wide at the base; anthers oblong-linear, 6–7(–8) mm long, grayish; pollen ca. 51.6 μm polar diam., ca. 78.3 μm longest equatorial diam. Style white, 66–78(–85) mm long, exserted 1–1.5 cm from the staminal cup, slightly assurgent; stigma deeply 3-lobed, 3–3.5 mm wide when receptive. Ovary oblong-ellipsoid, (8–)10–14 mm long, (4–)5–7.5(–8) mm wide, somewhat rostellate; ovules 9–12 per locule, superposed. Fruit and seed

FIGURES 102, 103. *Eucharis moorei* and *E. amazonica*.—102. *E. moorei* (*Meerow & Meerow 1141*, FLAS).—103. *E. amazonica* (*Schunke 14179*, FLAS).

imperfectly known, capsule reported to be green and the seed ellipsoid with a black testa. Chromosome number: $2n = 68$.

Distribution. An understory herb of lower and mid-montane rain forest of northeastern Peru, most prominently in the Huallaga valley in the vicinity of Moyobamba and Tarapoto (Fig. 99), 500–1,500 m. Widely cultivated throughout the warm tropics and as a house and greenhouse plant in the temperate zone. Occasionally adventive in the West Indies and probably elsewhere. Flowering at least twice per year, (May–)July–August(–September) and December–March.

Vernacular names. Amangais blanco, amangay, flor de cebolla, azuzena, Amazon lily, Eucharist lily.

Additional specimens examined. PERU. HUÁNUCO: Huánuco, Tingo María, 20 Aug. 1940, *Asplund 13214* (S); Huánuco, Tingo María, hwy. La Oroya–Tingo María,

Mar. 1977, *Boeke 1196* (NY); Leoncio Prado, Rupa Rupa, Las Palmas, km 18.5 a la carretera Tingo María–Huánuco, 756–800 m, 22 July 1984, *Schunke 14055* (F, FLAS, MO); Leoncio Prado, Rupa Rupa, Castillo Grande, al oeste de Tingo María, 24 July 1984, *Schunke 14057* (COL, F, FLAS, GH, K, MO, NY, UC, US); Huánuco Puerte Durand north of Huánuco, Río Chinchao valley, 7 Nov. 1938, *Stork & Horton 9880* (F, US); vicinity of Afilador, 670 m, *Woytkowski 101* (F). SAN MARTÍN: Lamas, Lamas, on trail from Tabalosos to Lamas, along Río Cumbaquiri, ½ hour W of Río Mayo, ca. 1,500 ft., 13–15 Sep. 1937, *Belshaw 3416* (F); near Uchiza, Huallaga valley, 500–550 m, 6 Aug. 1948, *Ferreyra 5154* (MO); Zepaelacio near Moyobamba, 1,200–1,600 m, Mar. 1934, *Klug 3559* (F, G, GH, K, NY, S US); Pachiza, Río Huayabamba, 1 Aug. 1959, *Mathias & Taylor 3974* (F); Roque, 9 Aug. 1925, *Melin 92* (S); between Balsapuerto and Moyobamba, 3,000 ft., *Sandeman s.n.* (BM); Lamas, Lamas, Fundo San Rafael, sector Santana, near Quebrada Chupishiña, 800 m, 5 Dec. 1984, *Schunke 14171* in part (FLAS); Moyobamba, 100[?]–1,100 m, *Weberbauer 4642* (G); Lamas, near Tarapoto, 840 m, Dec. 1929, *Williams 6348* (F, US); San Roque, 1,350–1,500 m, Feb. 1930, *Williams 7802* (F).

Meerow & Dehgan (1984a) re-established *Eucharis amazonicas* distinct from *E.* ×*grandiflora*, a taxon with which it has been confused since its description by Planchon (1857). The species is indigenous only to Peru, in the upper and middle Huallaga valley, but is grown worldwide in tropical regions and may be sporadically adventive. The species has a somatic chromosome number of $2n = 68$ (Meerow, 1987b; Nagalla, 1979) and is at least partially sterile. No specimen of *E. amazonica*, in contrast to most other species, has ever been collected in fruit; pollen stainability is only 50–65%; and viable seed has never been produced in cultivation. It is therefore conceivable that all populations of *E. amazonica* constitute a single clone. Its distribution throughout its narrow range may have been promoted by transient agriculturists. I believe *E. amazonica* to be a triploid-derived ($3x-1$) Peruvian isolate of either *E. moorei* or a possibly extinct mutual ancestor. The morphological differences between these taxa are cryptic and virtually impossible to discern in most dried material without dissection of the ovary. Their close relationship is further supported by the presence of secondary vascular bundles in the petiole of both taxa, although much smaller in *E. amazonica*.

DOUBTFUL OR EXCLUDED NAMES IN *EUCHARIS*

Eucharis galanthoides hort., Linden, usually cited as *E. galanthoides* (Klotzsch) Linden (e.g., by Macbride, 1936; Traub, 1963), Ann. Cat. Hort. 17: 4. 1862. This combination is based on the erroneous assumption that Linden's *Eucharis galanthoides* was based on *Mathieua galanthoides* Klotzsch (Meerow, 1987a). The actual basionym was *Pancratium galanthoides*, a name under which Linden received material of a *Eucharis* collected by Gustav Wallis in Amazonas. *Mathieua galanthoides* was collected by Warscewicz in xeric, northwestern Peru (*Warscewicz s.n.*, B). No type has been located for Linden's plant, and the name *E. galanthoides* merely appeared as a listing in his catalog. It is likely referable to *E. castelnaeana* (Baillon) Macbride.

Eucharis himeroessa Sandwith ex Standley, Herbertia 3: 4. 1936. This name was never validly published with diagnosis or description. It was applied to a population of *E. bouchei* var. *bouchei* Woodson & Allen from San José Province in Costa Rica.

Eucharis paradoxa hort., T. Moore, Gard. Chron. 1: 242. 1876. A listed name, never described or illustrated, supposedly applied to the plant later described as *Caliphruria subedentata* Baker.

Pancratium galanthoides hort., Linden, Ann. Cat. Hort. 17: 4. 1862. See discussion under *Mathieua galanthoides*.

Caliphruria Herbert, Edwards's Bot. Reg. 30 (misc. no. 83): 87. 1844. *Urceolina* subg. *Caliphruria* (Herbert) Traub, Pl. Life 27: 57–59. 1971. TYPE SPECIES: *Caliphruria hartwegiana* Herbert.

Small bulbous perennial herbs. Leaves glabrous, petiolate, persistent or rarely hysteranthous; petiole subterete; lamina ovate, ovate-elliptic or elliptic, slightly succulent, apically acute or acuminate, basally attenuate to the petiole, margins nonundulate, dark green and smooth-surfaced adaxially, lighter green abaxially, the cuticle of the abaxial epidermis thickly striate or ridged, hypostomatic or with adaxial stomata only near and upon the midrib. Inflorescence scapose, umbellate; scape slender, terminating in 2 marcescent bracts enclosing the flowers before anthesis. Flowers pedicellate, (3–)5–10(–12) on thin pedicels, each subtended by a linear-lanceolate bracteole, declinate or subpendulous by the laxness of the pedicel, 2–4 cm long, without noticeable fragrance, white, funnelform or funnelform-tubular, protandrous; perianth tube funnelform, dilating gradually from the base, tinged green below, or subcylindrical and white throughout, straight; limb of 6 lanceolate, ovate or elliptic tepals in 2 subequal series, the segments imbricate for half their length, diverging in their distal half. Stamens connate only at the base, forming a short,

membranaceous staminal cup, variously toothed or edentate between each filament, distal portion of the filament narrowly subulate or linear, subequal; anthers oblong, erect at anthesis, eventually versatile; pollen grains medium-sized (longest equatorial axis ca. 50 μm), the exine finely reticulate. Style filiform; stigma trilobed, papillae multicellular. Ovary globose, green, with septal nectaries; ovules ellipsoid, (1–)2–7 per locule, medially superposed, placentation axile. Fruit a thin-walled, leathery, yellow-green, loculicidal capsule; seeds few per locule; globose or compressed-ellipsoid, ca. 3–5 mm long, testa black or brown. Chromosome number: $2n = 46$.

Four species, three endemic to western Colombia, one to Peru.

KEY TO THE SPECIES OF *CALIPHRURIA*

1a. Perianth more than 2 cm long; tube 9 mm or more long.
  2a. Perianth tube 9–13.5 mm long; stamens 5.8–6.8 mm long, bidentate between each stamen, length of teeth at least ½ the length of the free filament ..... 1. *C. hartwegiana*
  2b. Perianth tube 15–25 mm long; stamens 9 or more mm long, edentate or occasionally with 1–2 teeth between each stamen, teeth never more than 1/10 the length of the free filament ..... 2. *C. subedentata*
1b. Perianth equal to or less than 2 cm long; tube less than 9 mm long.
  3a. Leaves hysteranthous; perianth tube funnelform; stamens less than 5 mm long, more or less fasciculate, bidentate, teeth much exceeding the free filament in length, free filament 1–2 mm long, ovules 1–2 per locule ..... 3. *C. tenera*
  3b. Leaves persistent; perianth tube subcylindrical; stamens 7–10 mm long, divergent, edentate, free filament 7–9 mm long, ovules 4–5 per locule ..... 4. *C. korsakoffii*

1. Caliphruria hartwegiana Herbert, Edwards's Bot. Reg. 30, misc. no. 83: 87. 1844. *Eucharis hartwegiana* (Herbert) Nicholson, Illus. Dict. Gard. 1884. *Urceolina hartwegiana* (Herbert) Traub, Pl. Life 27: 57–59. 1971. The species as described by Herbert from Hartweg collections made near Guaduas, Colombia, lacks a holotype, and I have not located any specimen which could be designated as lectotype. The following neotype is herein proposed. NEOTYPE: Colombia. Huila: Río Magdalena near Paicol, 600–1,200 m, *Lehmann 6376* (neotype, K). Figure 104B.

Bulb globose with a brown tunic, ca. 32.8 mm diam., often apically articulated into a slender neck

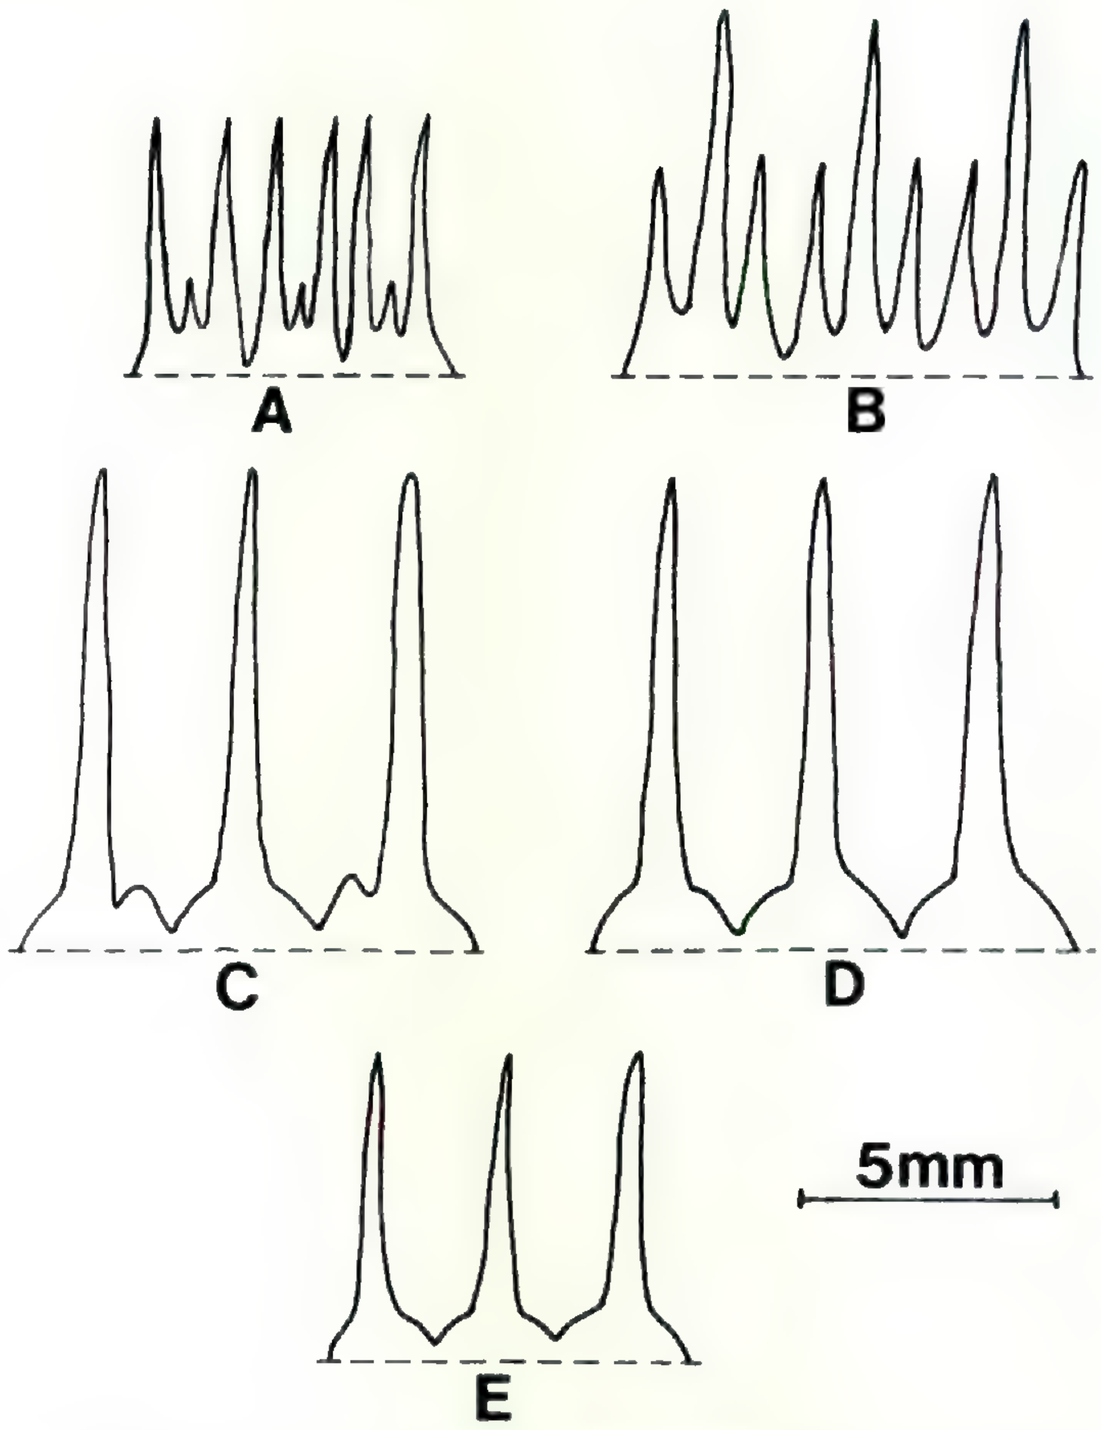

FIGURE 104. Androecial morphology of *Caliphruria* species.—A. *C. tenera* (*Triana 1289*, COL).—B. *C. hartwegiana* (neotype, *Lehmann 6376*, K). C, D. *C. subedentata*.—C. *Pittier 1009* (US).—D. Holotype, ex hort. *Beaufoy s.n.* (K).—E. *C. korsakoffii* (*Meerow 1096*, FLAS).

to 19.6 mm long. Leaves 2–4; petiole 13 cm long, 2.5–4.4 mm thick; lamina ovate to elliptic, 10–14 cm long, 3.8–6.3 cm wide, acuminate, shortly attenuate to the petiole at the base. Scape 28–31 cm tall; bracts lanceolate, 13.5–16.8 mm long and ca. 3 mm wide at the base; inner bracteoles successfully smaller and narrower. Flowers 5–7; pedicels 12.8–15.8 mm long, thin; perianth 19–26 mm long, white, except for the proximal 1/3–½ of the tube, this green; tube funnelform, dilating gradually from the base, 9–13.5 mm long, ca. 2–3 mm wide at the base, 5–6 mm wide at the throat; limb spreading to 7.5–11 mm; tepals ovate-elliptic, the outer series ca. 14.8 mm long, 3.4 mm wide, acute-apiculate, the inner series ca. 12 mm long, 5 mm wide, obtuse. Stamens 5.8–6.8 mm long, narrowly subulate for most of their length, dilated to ca. 2.5 mm basally where connate, bidentate between each free filament; teeth ca. ½ the length of the free filament; free filament ca. 1.5 mm wide at point of insertion to cup; anthers 5.2–5.4 mm long, linear, versatile. Style 25 mm long, exserted ca. 2.4 mm beyond the limb; stigma 1.8 mm wide; ovary globose, 2.8–3.1 mm diam.; ovules 2–3 per locule, axile, medially superposed. Mature fruit and seed unknown.

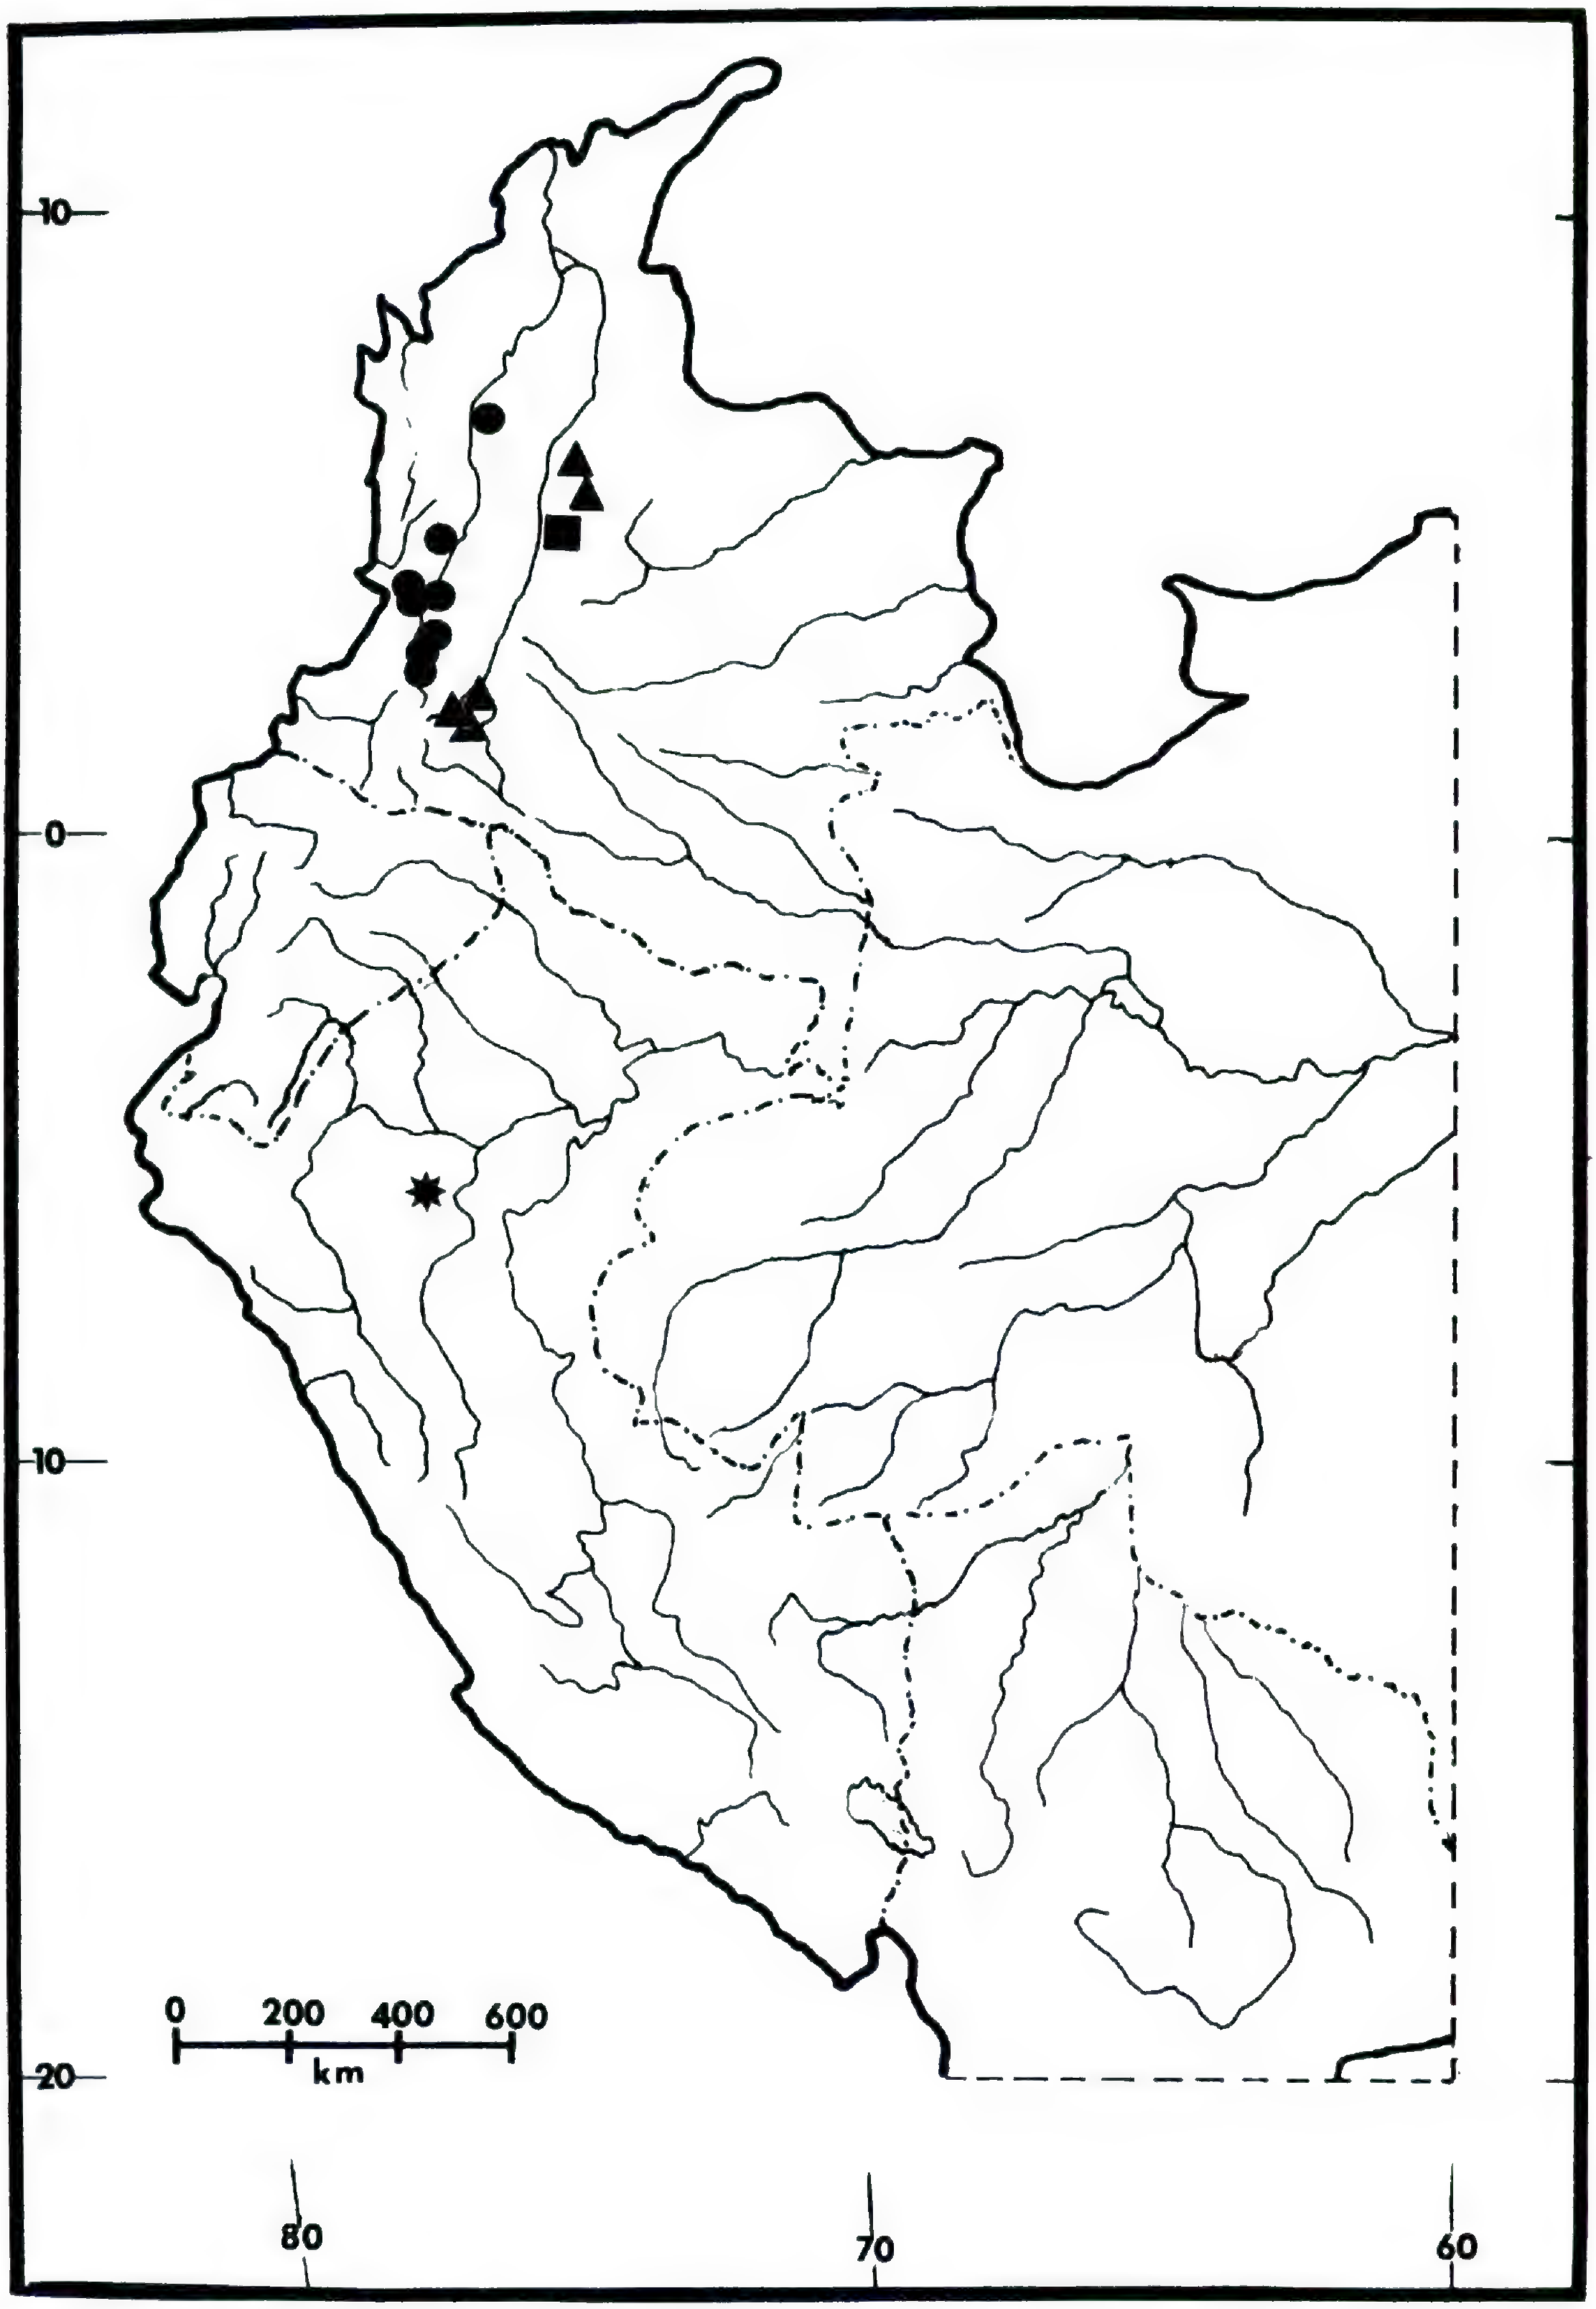

FIGURE 105. Distribution of species of *Caliphruria* in northwestern-central South America. *Caliphruria hartwegiana* (triangles), *C. korsakoffii* (star), *C. subedentata* (circles), and *C. tenera* (square).

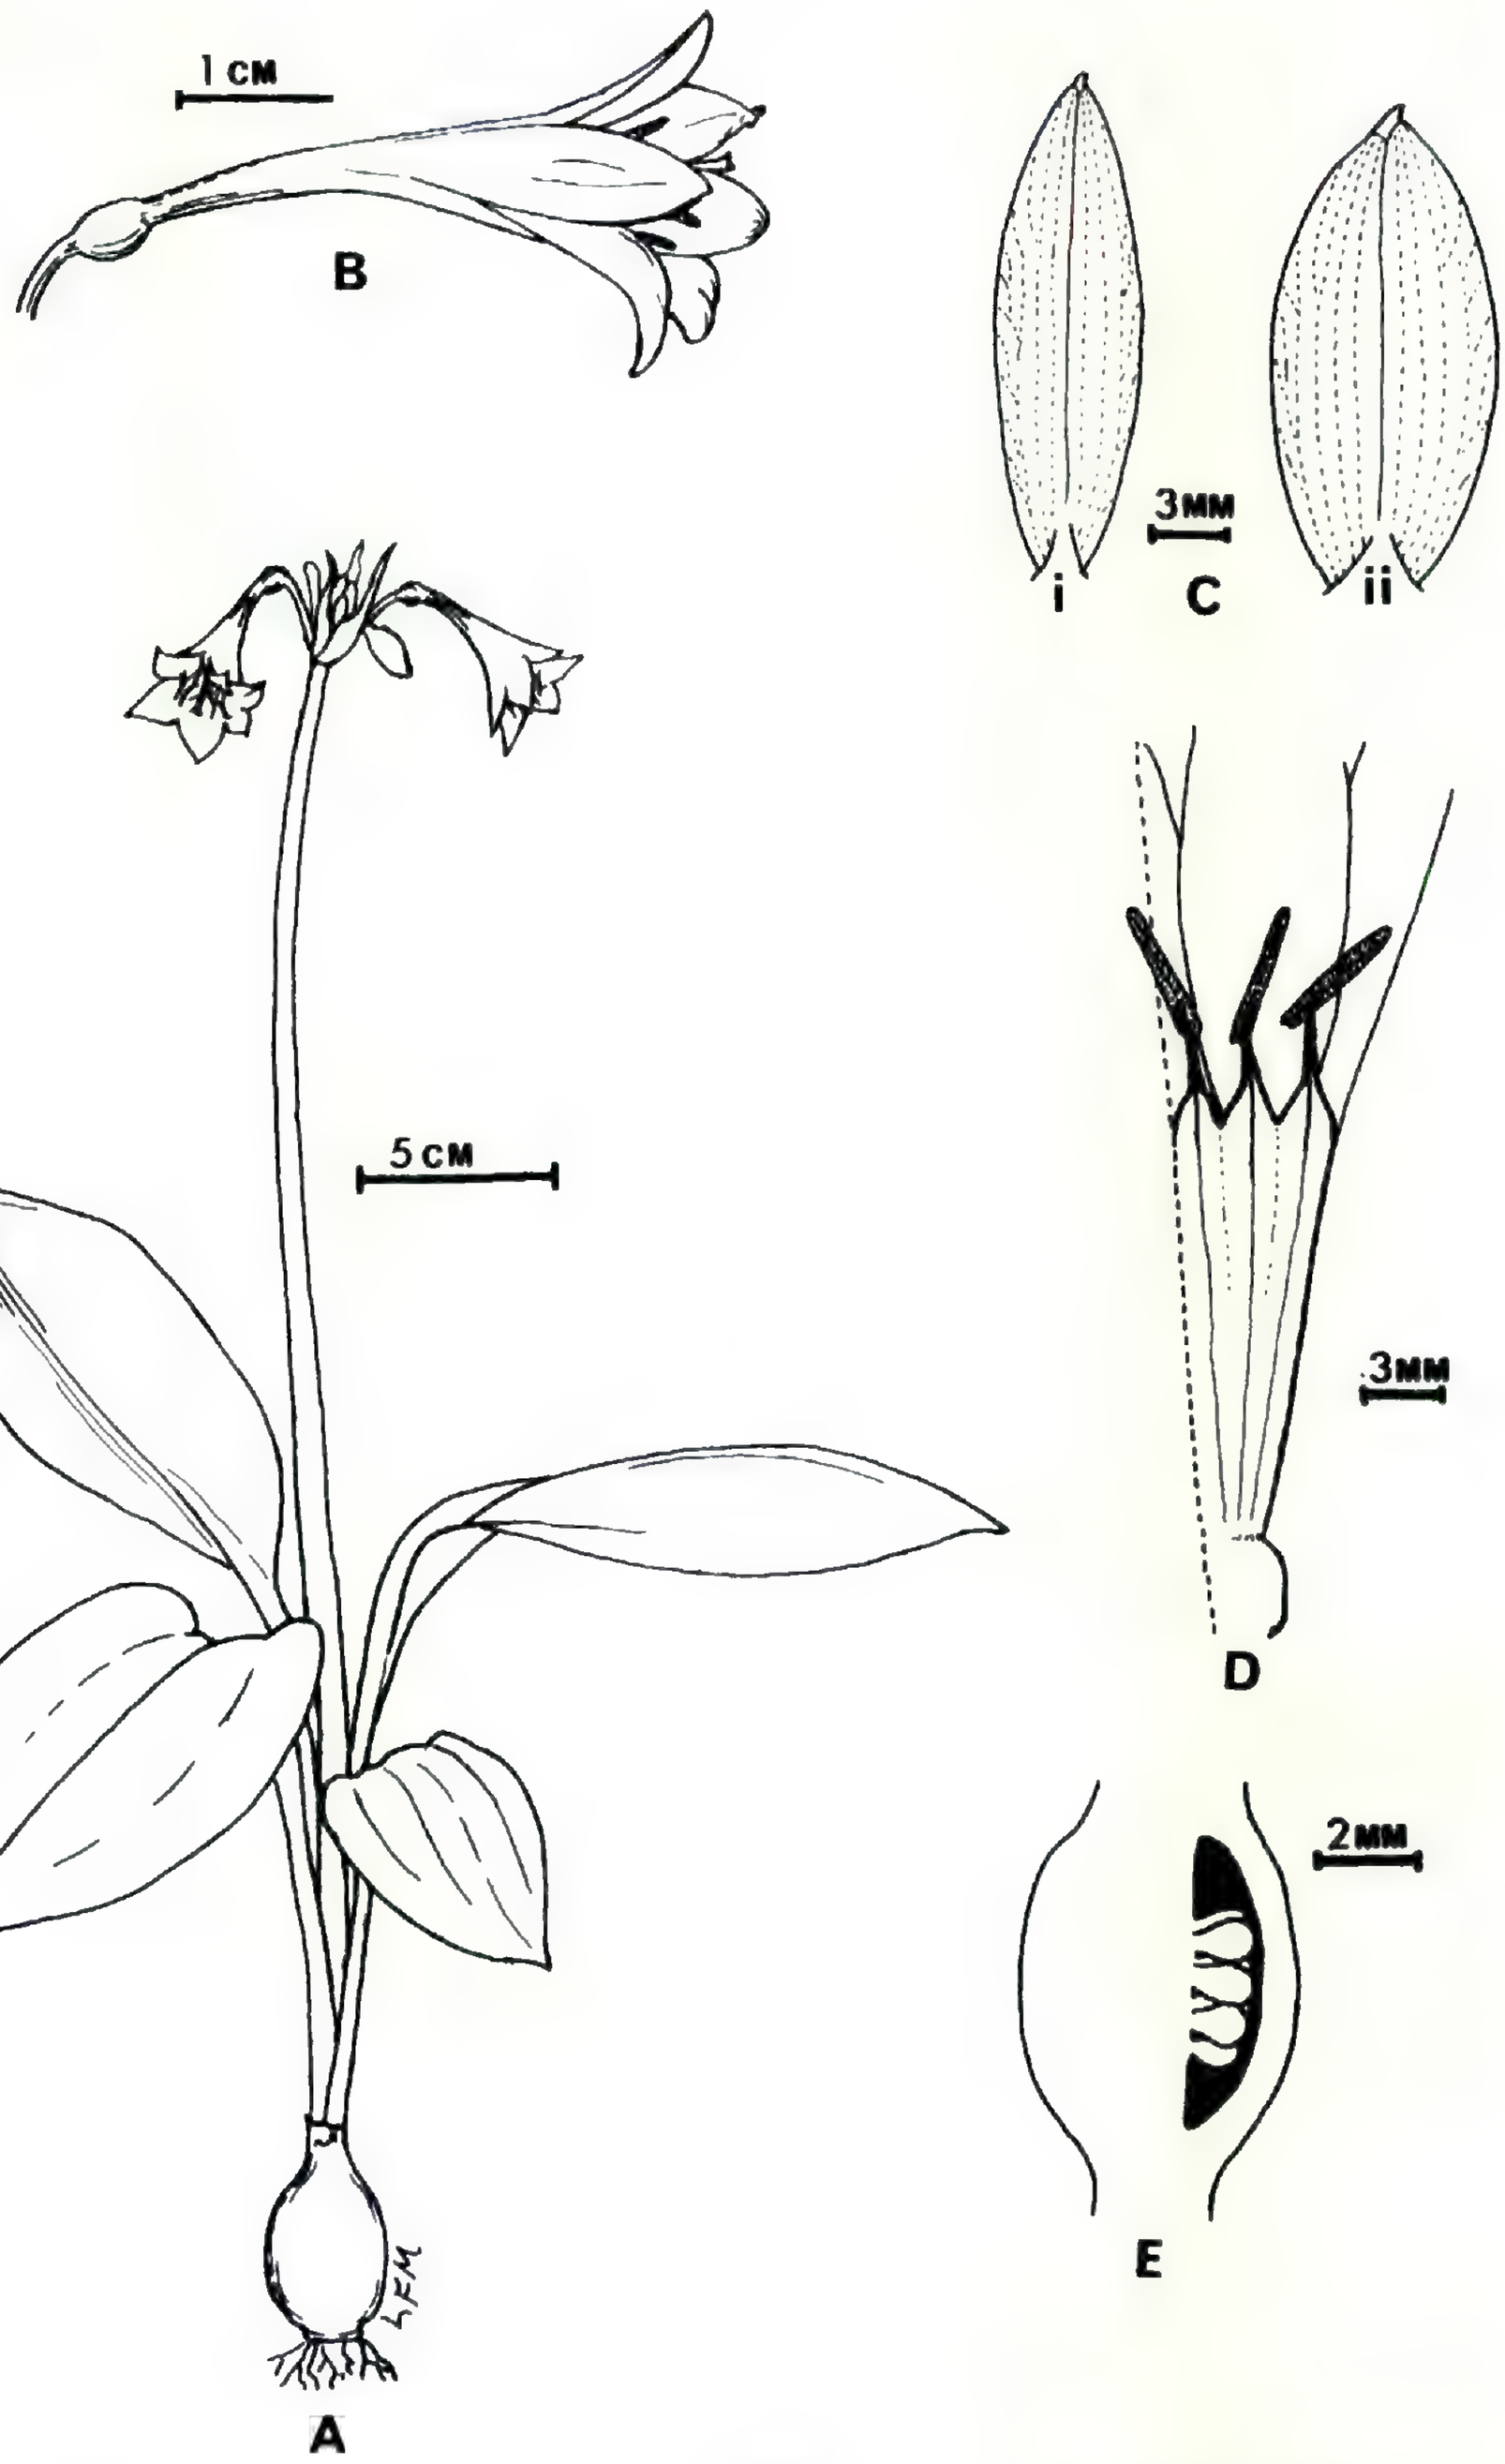

FIGURE 106. *Caliphruria subedentata* (*Meerow 1123*, FLAS).—A. Habit.—B. Flower.—C. Tepals. i, outer tepal; ii, inner tepal.—D. Longitudinal section through part of flower to show detail of androecium.—E. Ovary, longitudinal section.

Distribution. Rare in western-central Colombia, in the understory of montane forests of the Río Magdalena Valley (Fig. 105), 600–2,350 m.

Additional specimens examined. COLOMBIA. CUNDINAMARCA: Caparrapi, 1,275 m, 8–13 June 1939, *García-Barriga 7713* (COL). EX HORT.: *s.n.* (K); 1882, *s.n.* (GOET). HUILA: forest around Finca Mehrenberg, 2,350 m, 6 July 1984, *D'Arcy et al. 15634* (MO); Municipio de La Plata, Vereda Agua Bonita, Finca Merenberg, 1,200–1,300 m, 15 July 1975, *Díaz et al. 534* (COL).

This seldom-collected species is distinguished from *C. subedentata* by its smaller flowers and short stamens with long teeth interposed between the filaments (Fig. 104B).

2. Caliphruria subedentata Baker, Curtis's Bot. Mag. 103: t. 6289. 1877. *Eucharis sub-*

edentata (Baker) Bentham & Hooker, Genera Plantarum 2: 731. 1883. *Urceolina subedentata* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: ex hort. *Beaufoy s.n.* (holotype, K; photo of type, COL). Figure 106.

Eucharis fosteri Traub, Pl. Life 7: 36. 1951. *Urceolina fosteri* (Traub) Traub, Pl. Life 27: 57–59. 1971. TYPE: Colombia. Cauca: above Cali on road to Buenaventura, 2,000 ft., collected by M. B. Foster, 5 Dec. 1946, *Traub 17* (holotype, MO).

Bulb globose-subglobose with a brown tunic, 22–45(–63) mm long, 20–32 (–44.5) mm wide, often apically articulated into a slender neck 11.8–23.5 mm long and 10–15.7 mm wide, offsetting vigorously. Leaves 2–4; petiole 10–28(–37) cm long, 4–7 mm thick; lamina ovate, ovate-elliptic, or elliptic, 14.5–19.5(–21) cm long, (4.5–)7–10 cm wide, acuminate, shortly attenuate to the petiole. Scape 25–40 cm tall, slender, 2.5–5.5 mm diam.; bracts 13–25.5(–30.5) mm long, 3–5.2 mm wide at base; inner bracteoles 5–14 mm long. Flowers (3–)5–7(–8); pedicels (13.6–)15.2–28(–44.3) mm long, thin, ca. 1 mm diam.; perianth (24–)31.6–39(–44.8) mm long, white except for the distal ⅓–½ of the tube, this green; tube funnelform, dilating gradually from the base, 15–25 mm long, ca. 2 mm wide at the base, 5–8 mm wide at the throat; limb spreading to 12.5–21 mm wide, tepals ovate-elliptic; outer series (15–)17.5–22.5 mm long, 5–8 mm wide, acute-apiculate; inner series (13.5–)15.8–20 mm long, 7–10 mm wide, obtuse and minutely apiculate. Staminal cup less than 1 mm long, edentate, rarely with 1–2 small teeth between all or some of the filaments, white; filaments narrowly subulate-linear for most of their length, (8–)9–11.5(–14.6) mm long, dilating to 1.5–2.5 mm at their point of insertion; tooth, when present, 1 mm or less long; anthers (5–)6.2–7(–7.5) mm long, linear; pollen grain ca. 39.3 μm polar diam., ca. 50.9 μm longest equatorial diam. Style (28.9–)30–40(–45) mm long, exserted 4–6 mm beyond perianth, white; stigma 3-lobed, 1–1.5(–2.5) mm wide. Ovary globose-ellipsoid, 3–5 mm long, 2.5–5 mm wide; ovules (2–)3–5(–7) per locule, axile, superposed. Capsule ca. 1 cm diam.; seeds 1–2 per locule, compressed-ellipsoidal, 5–7 mm long, ca. 3–5 mm diam.; testa black, rugose.

Distribution. Understory of lower and middle montane forests of western Colombia in the cordilleras Occidental and Central, chiefly in the Río Cauca valley (Fig. 105), (760–)1,100–1,800 (–2,000) m. Flowering at any time of the year.

Additional specimens examined. COLOMBIA. CAUCA: Santander de Quilichao; selva densa en "Río Chiquito," 2,000 m, 6 Oct. 1954, *Fernandez 2795* (COL); Río Cauca, 1,400 m, Sep. 1881, *Lehmann 939* (BM, G); Caloto, 1,200–1,500 m, June 1883, *Lehmann 2885* (G); Quebrada Guatica, 1,800 m, *Lehmann 3269* (K); Cajamarca, *Lehmann s.n.* (K); Caloto, 1,200–1,500 m, June 1880, *Lehmann s.n.* (K); along Río La Paila above Corrinto, Central Cordillera, 1,400 m, 19 Jan. 1906, *Pittier 1009* (US); vicinity of Medellín, 23 Mar. 1927, *Toro 111* (NY). VALLE DE CAUCA: Río Dagua Valley, La Margarita, ca. 760 m, Apr. 1939, *Killip 34872* (US); "La Manuelita," Palmira, 1,090–1,100 m, May 1922, *Pennell & Smith 6182* (US). Bull, *s.n.* (K); ex hort. Linden, *s.n.* (K).

Caliphruria subedentata is the most common and variable species of *Caliphruria*, at one time found throughout the moist lower and middle montane forests of the slopes of the cordilleras Central and Occidental west of 76°W longitude (Fig. 105), and chiefly those surrounding the Cauca Valley. Much of this forest type has been destroyed in western Colombia so the species is no longer abundant. In the course of fieldwork in western Colombia in 1984, I was not able to find *C. subedentata* in its historical localities nor in the remnants of lower and middle montane forest that I explored. The species may yet persist in more inaccessible forested sites. Living material received from Mr. Thomas Fennell was said to have been collected in Ecuador, but this information is undocumented. At present, I have seen no Ecuadorean specimens of *Caliphruria*, nor encountered populations in the field.

Within the range of *C. subedentata*, variation in leaf size, flower size, dentation of the androecium (Fig. 104C, D), and number of ovules is evident, but these patterns are for the most part continuous and/or mosaic in distribution, rendering recognition of subspecific taxa inappropriate. Though Baker (1877) characterized the species by the presence of one or two small teeth between the free filaments, the flowers present on the type specimen of *C. subedentata* are completely edentate. Clonotypic material of the taxon described by Traub (1951) as *E. fosteri* is distinguishable from other living material of *C. subedentata* only by its slightly smaller leaves and flowers.

3. Caliphruria tenera Baker, Handbook of the Amaryllideae, p. 112. 1888. *Eucharis tenera* (Baker) Traub, Pl. Life 23: 65. 1967. *Urceolina tenera* (Baker) Traub, Pl. Life 27: 57–59. 1971. TYPE: Colombia. Río Magda-

FIGURE 107. *Caliphruria korsakoffii* (*Meerow 1096*, FLAS).

lena, Aug. 1844, *Goudot s.n.* (holotype: K; isotype: P).

Bulb globose or ellipsoid, ca. 25 mm diam. or 30 mm long × 17.5 mm wide, sometimes apically articulated into a short neck 10 mm long × 5 mm wide; tunic grayish brown or tan. Leaves hysteranthous, not seen. Scape terete, slender, 16–27 cm tall, 1–2 mm diam.; bracts linear-lanceolate, 17–28.3 mm long; inner bracteoles linear, the longest to 14.5 mm. Flowers 5–10; pedicels 14–23.2 mm long, thin; perianth 17–19 mm long, funnelform, white; tube 8.5–9.5 mm long, funnelform, dilating gradually from 1.3 mm wide at the base to 3–4 mm at the throat; limb spreading to 15.5 mm; tepals ovate to elliptic, the outer series 8.5–11.2 mm long, 2–2.5 mm wide, acute-apiculate; the inner series 8–10 mm long, 2.8–3.8 mm wide, obtuse. Stamens 3–5 mm long, each stamen bidentate, 1.5–2.2 mm wide, the free filament inserted between the teeth; teeth much exceeding the free filament, 3–4 mm long; free filament 0.8–1.5 mm long, linear; anthers 4–5.5 mm long, linear; pollen grain ca. 35.2 μm polar diam., 53.7 μm longest equatorial diam. Style 18–21 mm long; stigma 3-lobed, 1 mm wide. Ovary globose, 1.8–2.7 mm diam.; ovules 1–2 per locule, axile, medially superposed. Fruit and seed unknown.

Distribution. Colombia, valley of the Río Magdalena (Fig. 105), 400 m.

Additonal specimen examined. COLOMBIA. CUNDINAMARCA ?: "Prov. Bogota," Copo la Parada, 400 m, July 1853, *Triana 1289* (COL, US, photo GH).

Caliphruria tenera is the smallest-flowered Colombian representative of *Caliphruria*. It is readily distinguished by its hysteranthous leaves and the long teeth of the androecium which greatly exceed the short free filament (Fig. 104A). Unfortunately, *C. tenera* has not been re-collected since 1853. The hysteranthous leaves of this species suggest adaptation to drier habitats than usually characteristic of the genus. Pockets of xeric vegetation do occur in the vicinity of the type locality (Cuatrecasas, 1958).

4. **Caliphruria korsakoffii** (Traub) Meerow, comb. nov. *Eucharis korsakoffii* Traub, Pl. Life 23: 85–87. 1967. *Urceolina korsakoffii* (Traub) Traub, Pl. Life 27: 57–59. 1971. TYPE: Peru. San Martín: 40 km from Moyobamba, Hierra waterfalls, 1,500 m, ex hort. J. N. Giridlian from bulbs collected by Lee Moore, 16 July 1966, *Traub 1060* (holotype, MO). Figure 107.

Bulb ± globose, 31 mm long, 29.3 mm wide, without an appreciable neck, tunic brown, offsetting weakly. Leaves 2–4; petiole 4.5–10 cm long, 3–4 mm thick; lamina ovate-lanceolate to narrowly elliptic, 13–17 mm long, 3.3–4.8 mm wide, acute-acuminate, basally attenuate to the petiole, cuticle of the abaxial epidermis thickly ridged. Scape 15–25 cm tall, 3.5–3.7 mm diam.; bracts lanceolate, 19–25 mm long, 5.5 mm wide at the base; inner bracteoles 8.5–22 mm long. Flowers 10–12, 15–20 mm long, funnelform, white, declinate to slightly ascendent; pedicels 2–4 cm long; tube subcylindrical, straight, 4–6 mm long, 2 mm wide at base, 3.2 mm wide at throat; limb spreading to ca. 2

cm; outer tepals lanceolate, 10–18.5 mm long, 4–5 mm wide, acute-apiculate; inner tepals ovate, 7.5–16 mm long, (5–)7–8 mm wide, obtuse and minutely apiculate. Stamens (7–)9.5–10 mm long, 0.7 mm wide at the base, edentate, diverging distally, narrowly subulate, white; anthers 3–4 mm long, oblong, dorsifixed in lower third, versatile; pollen grain ca. 32.3 μm polar diam., 50.4 μm longest equatorial diam. Style 16–21 mm long, white, slightly longer than limb segments; stigma 3-lobed, (1.2–)2.5–2.7 mm wide. Ovary globose-ellipsoid, 3.5–5 mm long, 2–3 mm wide; ovules 4–5 per locule, medially superposed. Capsule ca. 1 cm diam., yellow-green, thin-walled; seeds 1 per locule, globose, ca. 3 mm diam., testa brown. Chromosome number: $2n = 46$.

Distribution. North-central Peru (Fig. 105) at 1,500 m. Known only from the type locality in the understory of dense lower montane rain forest in humic topsoil on steep slopes, often growing wedged in the crevices of rocks.

Additional specimens examined. EX HORT.: Clone of type collection, *s.n.* (K); clone of type collection, July 1964, *Traub s.n.* (MO); clone of type collection, May 1982, *Meerow 1096* (FLAS).

Caliphruria korsakoffii is the only species of *Caliphruria* presently known outside of Colombia. In the size of the flower this species has affinity with *C. tenera* but can be distinguished by having evergreen leaves, subcylindrical tubes, and edentate, divergent, and longer stamens (Fig. 104E), coarser pollen exine reticulation, more numerous ovules, and higher altitudinal limits. The seeds of *C. korsakoffii* have a brown testa; those of *C. subedentata* are black. The ridged cuticle of the abaxial leaf surface of *C. korsakoffii* (Fig. 12) is quite different from the narrow cuticular striations of *C. subedentata* (Fig. 11). The morphological novelties exhibited by *C. korsakoffii* suggest considerable isolation from the Colombian taxa of *Caliphruria*.

THE SYSTEMATICS AND EVOLUTION OF *LUDWIGIA* SECT. *MICROCARPIUM* (ONAGRACEAE)[1]

Ching-I Peng[2]

ABSTRACT

Ludwigia sect. *Microcarpium*, which consists of 14 species distributed mainly in the southeastern United States, is the second-largest section in the genus, the largest being the phylogenetically central sect. *Myrtocarpus* of South America.

Plants of *Ludwigia* sect. *Microcarpium* are morphologically diverse; they form a polyploid complex of four diploids, eight tetraploids, two hexaploids, and one octoploid. They are facultatively autogamous herbaceous plants capable of reproducing both sexually and asexually (forming stolons late in the flowering season). Based on extensive crossing experiments as well as field and herbarium studies, the relationships among species of this section have been clarified. Internal genetic barriers between species are nonexistent, and natural hybridization is fairly common.

Among the diploid species, *L. linifolia* and *L. linearis* have very narrow leaves, petaliferous flowers, and elongate capsules. The two species, however, differ chromosomally by one reciprocal translocation. F_1 hybrids between them are vigorous, have ca. 50% stainable pollen, and produce moderate quantities of viable seeds. *Ludwigia stricta*, the Cuban endemic, is apparently most closely allied to *L. linifolia*, based on morphological evidence, but has not yet been studied biosystematically. *Ludwigia microcarpa*, in contrast, has spatulate-obovate leaves, small, apetalous flowers, and minute obconical capsules. Artificial hybrids between *L. microcarpa* and either *L. linearis* or *L. linifolia* form neither stainable pollen nor seeds; for the most part, the chromosomes of these hybrids do not pair in meiosis. *Ludwigia microcarpa* probably evolved relatively early from outcrossing ancestors.

Although the nine tetraploid members in sect. *Microcarpium* are sharply distinct morphologically, they can be crossed in any direction in the experimental greenhouse and form fertile F_1 offspring. Natural hybrids in plants of this group are also fairly common and in some cases blur the boundaries of the species. Somewhat surprisingly, none of the extant diploid species are considered to be direct ancestors of the tetraploids, based on cytogenetic studies.

The two hexaploid species, *L. alata* and *L. simpsonii*, are not closely related to each other. The affinity of *L. alata* is definitely with the tetraploid species group. Hybrids between *L. alata* and any other tetraploid species consistently exhibit a modal configuration of 16 II and 8 I in meiosis. Based on its morphology and the cytology of hybrids involving it, *L. alata* may have originated through hybridization between a tetraploid species, possibly *L. lanceolata*, and the diploid *L. microcarpa*, or populations ancestral to each of these species.

Ludwigia simpsonii, on the other hand, is closely related to *L. curtissii*, which is the only octoploid in sect. *Microcarpium*. The two species are unique in sect. *Microcarpium* in having loculicidal capsules and, together with the diploid *L. microcarpa*, in having spatulate-obovate cauline leaves. Cytogenetic and morphological studies suggest that the octoploid *L. curtissii* may have resulted from hybridization of *L. simpsonii* and a petaliferous diploid species, possibly *L. linifolia*, *L. linearis*, or populations like them. *Ludwigia microcarpa* is involved in the formation of the hexaploid *L. simpsonii* and therefore that of the octoploid *L. curtissii*. The other progenitors of *L. simpsonii* are not clear, but some species in sect. *Dantia* or populations ancestral to them with apetalous flowers, opposite leaves, and a prostrate habit are likely candidates.

[1] This research was supported by the U.S. National Science Foundation under Grant No. BSR82-14879 to Dr. Peter H. Raven. I express sincere appreciation to Dr. Raven for encouragement and intellectual input throughout this study, and to the Missouri Botanical Garden for providing excellent support and facilities. I am grateful to Peter C. Hoch for helpful discussions and assistance with the manuscript and to David E. Boufford for reviewing the manuscript. I thank P. P. Lowry II for photographing type materials at P; Karen Prescher for cataloging herbarium specimens and preparing distribution maps; Emily Colletti and Jim Henrich for care of greenhouse plants; Wanling Peng, Chien-Chu Chen, and Yu-Mei Chiou for their excellent illustrations; and Gloria Hoch for expertly typing the manuscript. I am also thankful to David E. Boufford, Emily Wood, Jychian Chen, and my wife, Wanling Peng, who accompanied and assisted me in the field. Further gratitude is due curators of the following herbaria for loans: A, AAU, B, BM, BOON, C, CAS, CHARL, CM, DH, DS, DUKE, E, ENCB, F, FI, FLAS, FSU, FTG, GA, GH, IJ, JE, LL, LSU, M, MEXU, MISS, MISSA, MO, MSC, NA, NCSC, NCU, ND, NDG, NO, NY, P, PH, RSA, S, SMU, TAES, TENN, TEX, TI, U, UNA, UPS, US, USCH, USF, VA, VDB, W, WAG, WCUH, WU, Z, and East Carolina University Herbarium. Finally, I express my appreciation to the Institute of Botany, Academia Sinica, Taipei, Taiwan, Republic of China, for granting me leaves of absence to work on this study.

ANN. MISSOURI BOT. GARD. 76: 221–302. 1989.

To summarize, recombination from somewhat differentiated populations, followed by polyploidization and the maintenance of well-adapted genetic strains by a combination of autogamy and vegetative reproduction, appears to have played a central role in the evolution of the species of *Ludwigia* sect. *Microcarpium*.

Ludwigia is a distinct genus of Onagraceae and is the only member of Jussiaeeae. Fossil records of pollen suggest that it is archaic and has existed at least 50 million years since the middle Eocene in both the Northern and Southern hemispheres (Gonzales Guzmán, 1967; Rouse, 1962; Bratseva, 1969). Except for its chromosome structure and number, which appear to be relatively specialized (Kurabayashi et al., 1962), *Ludwigia* is one of the least specialized genera as to wood anatomy (Carlquist, 1975, 1982), floral anatomy (Eyde, 1977, 1978, 1981), and leaf anatomy (Keating, 1982). Based primarily on its unusual nectary position, ovular vasculature, and independently derived epigyny, Eyde (1977, 1978, 1981) demonstrated that *Ludwigia* represents a distinct branch from the common ancestor of the family, with all other living genera on the other branch; in Hennigian terms, it is the sister group of the remainder of the family.

The genus *Ludwigia* comprises 82 species that are diverse enough, especially in fruit, seed, and flower characters, to be classified in 23 sections, 14 of which are monotypic (Raven, 1963; Ramamoorthy & Zardini, 1987). Plants of *Ludwigia* are adapted to wet habitats in the tropics and subtropics. They probably originated in South America, the most important center of diversity for *Ludwigia*, and the area where the most primitive species are found (Ramamoorthy & Zardini, 1987). The genus, however, is also well represented in temperate North America and has three endemic species in temperate Asia.

In North America, there are 23 native *Ludwigia* species, characterized by having convex or elevated nectaries, tetramerous, haplostemonous flowers, pluriseriate ovaries, free seeds with narrow raphes, and herbaceous habits. Most of these plants are confined to the Atlantic and Gulf coastal plains of the United States, although some species are more widespread, and some extend into the islands of the Caribbean; one is endemic in Cuba. Based primarily on characters of capsules, mode of perennation, and phyllotaxy, the North American plants are classified into sect. *Ludwigia* (4 species), sect. *Dantia* (DC.) Munz (5 species), and sect. *Microcarpium* Munz (14 species). Table 1 summarizes the diagnostic characters of these three sections.

Based on his study of the structure and morphology of the capsules and nectaries of *Ludwigia*, Eyde (1981) considered sections *Dantia* and *Microcarpium* to comprise a closely knit group derived from the phylogenetically central, diplostemonous *Myrtocarpus* complex, whereas sect. *Ludwigia* is different enough to have arisen independently from the *Myrtocarpus* complex.

Section *Microcarpium* was selected for the present revision because it is the second-largest section of *Ludwigia* and is very diverse, because it has not been revised in light of recent new data and evolutionary concepts, and because several species of this section are variable and taxonomically difficult, with boundaries between species often blurred by intermediates.

The purposes of this revision are to clarify species limits, to determine the degree and significance of natural hybridization, and to analyze natural affinities among species of sect. *Microcarpium*. Toward this end, more than 7,000 specimens from 44 herbaria have been consulted for morphological studies and for mapping. Furthermore, I have made three extensive field studies in the coastal plains of the southeastern United States. Searches for possible natural hybrids were made in the field whenever taxa occurred sympatrically. Seeds and/or clonal transplants of all species were propagated at the Missouri Botanical Garden for chromosome determination and morphological study.

Taxonomic History

After the establishment of the genus *Ludwigia* in 1753 by Carl Linnaeus, the first group of North American species of sect. *Microcarpium* was discovered by the British botanist Thomas Walter (1788). Four of his species are currently recognized: *L. glandulosa*, *L. linearis*, *L. pilosa* (including *L. rudis*), and *L. suffruticosa*.

Jean Baptiste A. P. M. de Lamarck (1789, 1792) published "*Jussiaea brachycarpa*" and "*Ludwigia hirsuta*," based on materials collected from South Carolina. These names are synonyms of *L. glandulosa* and *L. pilosa* respectively, as Lamarck himself suspected.

The next botanist to study North American *Ludwigia* was Andre Michaux (1803), who described nine species of *Ludwigia* in his *Flora Boreali-Americana*. Of these, *L. microcarpa* is a member of sect. *Microcarpium*.

In 1814, Jean L. M. Poiret correctly added the

TABLE 1. Comparison of the native North American sections of *Ludwigia*.

Character	Sect. *Ludwigia* (4 species)	Sect. *Dantia* (5 species)	Sect. *Microcarpium* (14 species & 1 subspecies)
Habit	Perennial. Plants erect, lacking stolons; roots tuberous	Perennial. Plants creeping, rooting at nodes; roots fibrous	Perennial. Plants erect, usually stoloniferous (rhizomatous in one species); roots fibrous
Phyllotaxy	Leaves alternate	Leaves opposite	Leaves alternate
Capsules	Capsules pedicellate, opening by a terminal pore formed after abscission of the style base	Capsules sessile or pedicellate, irregularly dehiscent	Capsules sessile or short-pedicellate, ring-, loculicidal-, or peeled-dehiscent (see text)
Seed surface	Cells in parallel columns, transversely elongate to the seed length	Cells in parallel columns, transversely elongate to the seed length	Cells ± isodiametric or in parallel columns and either longitudinally or tranversely elongate to the seed length
Petals	Petals 8–15 mm long	Petals lacking or 2–10 mm long	Petals lacking (in 3 species 3–6 mm long); vestigial petals occasionally present in some primarily apetalous species
Nectaries	4 shallow ciliate depressions on the raised summit of the ovary, alternating with the sepals and stamens	4 raised and rounded lobes, surrounding the style base and alternating with the sepals and stamens	4 raised and rounded lobes, surrounding the style base and alternating with the sepals and stamens
Chromosome numbers	$n = 8$ (4 species)	$n = 8$ (1 species) $n = 16$ (2 species) $n = 24$ (2 species)	$n = 8$ (4 species) $n = 16$ (7 species & 1 subspecies) $n = 24$ (2 species) $n = 32$ (1 species)
Pollen grains	Shed as tetrads	Shed singly or as tetrads	Shed singly or as tetrads
Genetic compatibility	Self-compatible	Self-compatible	Self-compatible

new species *L. linifolia*, collected in the southern United States; it resembles but is quite distinct from *L. linearis*.

It was not until 1821 that the species of sect. *Microcarpium* were described by American botanists. Of the four species in sect. *Microcarpium* that Steven Elliott (1816–1821) described, *Ludwigia alata*, *L. sphaerocarpa*, and *L. lanceolata* are currently recognized, whereas *L. cylindrica* represents a synonym of *L. glandulosa* Walter. Although Elliott correctly differentiated *L. alata* from *L. lanceolata*, the striking superficial resemblance of the two species, especially in dried herbarium specimens, has constantly been a source of confusion among botanists (Long & Lakela, 1976; Raven & Tai, 1979; Godfrey & Wooten, 1981; Wunderlin, 1982; Clewell, 1985). The great distinctiveness of these two species in such characters as floral morphology, pollen and seed surface features, and chromosome numbers were only appreciated recently (Peng, 1988, and this study).

In 1836, *Ludwigia polycarpa*, a distinctive member of sect. *Microcarpium* distributed mainly in the northcentral United States, was discovered in Kentucky by Charles Wilkins Short and Robert Peter.

Shortly thereafter, John Torrey and Asa Gray (1838–1840), in *A Flora of North America*, proposed two varieties in sect. *Microcarpium*, i.e., *Ludwigia cylindrica β brachycarpa* and *L. capitata β pubens*. The former is currently recognized as the small-fruited, western subspecies of *L. glandulosa* (Peng, 1986), whereas the latter represents a natural hybrid between *L. suffruticosa* and *L. pilosa* (Peng, 1988).

In 1845, George Engelmann and Asa Gray described a densely pubescent variety of *Ludwigia linearis* from Texas. Owing to the complex variation pattern and the many intermediate populations found in the range of this species, however, the variety is not recognized in the present study.

Ludwigia stricta, the only Cuban endemic in

sect. *Microcarpium*, became known when August Grisebach (1866) described *Isnardia stricta* in *Catalogus Plantarum Cubensium*. The correct combination in *Ludwigia* was made by Francisco Adolfo Sauvalle (1873) in the *Flora Cubana*.

Alvin Wentworth Chapman added *Ludwigia curtissii* (1883) and *L. simpsonii* (1892) to the genus in his study of the flora of the southern United States.

John Kunkel Small named *Ludwigia simulata* in 1903, not knowing that it represented the hybrid *L. pilosa* × *L. lanceolata*. In 1933, he grouped, for the first time, plants of *Ludwigia* sect. *Microcarpium* under "Microcarpeae," and described from the Everglades of Florida *L. spathulifolia*, which has now been merged with *L. curtissii*.

Burghard Helwig in 1928 published *Ludwigia cubensis* from Cuba, which, however, is now considered as conspecific with *L. simpsonii* from Florida.

Merritt Lyndon Fernald and Ludlow Griscom (1935) described three additional varieties for the highly polymorphic *Ludwigia sphaerocarpa*, which itself may have originated as a result of hybridization and which now intergrades with *L. pilosa* freely (Peng, 1988). These hybrids are not recognized in this paper for reasons discussed elsewhere.

Paul Munz's monograph (1944, 1965) contained the most comprehensive treatment of North American *Ludwigia* in his time. In the 1944 paper, he formally delimited sect. *Microcarpium*. His concept has since been widely accepted. James Allan Duke (1955) was the first author to indicate and to provide examples of natural hybridization among North American species of *Ludwigia*.

In the course of my biosystematic study of *Ludwigia* sect. *Microcarpium*, a number of atypical specimens initially identified as *L. pilosa* Walter were shown to be a new species, which I subsequently named *L. ravenii* (Peng, 1984). This represents the last named species of sect. *Microcarpium*, and makes the total number of species of this section 14.

Morphology

Habit

All species in *Ludwigia* sect. *Microcarpium* are erect perennial herbs ranging from about 15 to 100 cm tall. Leafy, usually unbranched stolons are produced from the base of erect stems. The stolons creep along the surface of moist ground or float on water late in the flowering/fruiting season. Some species, however, may also send out stolons in the summer while they are actively flowering or even throughout their growing season. The stolons can be long (up to 2.5 m) and stout as in *L. pilosa* or short (5–15[–20] cm) and slender as in *L. microcarpa* and *L. ravenii*. The stolons give rise to erect shoots from their tips when the growing season resumes. In *L. polycarpa* the stolons are normally up to 15 cm long, and with leaves densely congested at the apex of stolons, overlapping one another and thereby protecting the apical meristem. This is apparently an adaptation to the severe winter that plants of *L. polycarpa* have to endure in the northern States. In *L. suffruticosa* stolons are uncommon. Instead, perennation is mainly by thick, somewhat woody, branched rhizomes. New shoots arise from the nodes of the rhizomes in growing season. It may be that in drier sandy situations, the plants persist by rhizomes, whereas in wet situations, the plants send out stolons.

In *Ludwigia curtissii* and *L. simpsonii*, stolons are rarely formed; the plants simply produce new shoots, which are ascending or decumbent at first and soon become erect from the base of the previous year's stem. They may not need to overwinter with low-profile stolons, as they are distributed mainly in Florida and the Caribbean Islands where the growing season is long and the winter is not severe.

Stems

Stems are usually well branched in most species of *Ludwigia* sect. *Microcarpium*. Plants of *L. suffruticosa* are, however, often simple. When they branch, the branches are few and usually arise from upper leaf axils beneath the compact inflorescences and characteristically overtop the main flowering/fruiting stems. Unbranched flowering stems are seen also in some populations of *L. curtissii*, *L. linifolia*, *L. microcarpa*, *L. simpsonii*, and *L. stricta*. The stems of some plants of *L. microcarpa* are distinctly zigzag. The stems of most species are slightly ridged; those of *L. alata* and *L. microcarpa* are often conspicuously ridged or winged. *Ludwigia pilosa* is the only species with nearly terete stems. The lower part of the stems of all species, when entirely submerged, is swollen and spongy.

Pubescence

Many species in *Ludwigia* sect. *Microcarpium* are glabrous to subglabrous; the margins of leaf, sepal, or bracteoles, and surfaces of fruit may sometimes be minutely strigillose or minutely papillose. Only *L. ravenii* and *L. pilosa* are consis-

tently hirtellous throughout. *Ludwigia sphaerocarpa*, a species that intergrades substantially with *L. pilosa*, is variable in many aspects, especially pubescence. Populations of *L. sphaerocarpa* range from being completely glabrous to densely strigillose throughout. Similarly variable is *L. linearis*, but no interspecific hybridization has apparently played a role here. The pattern of the distribution of hairs in *L. suffruticosa* is especially interesting: some plants are completely glabrous; some plants are hirtellous either on the terminal inflorescence or on the basal stems (including stolons/rhizomes), or both, but are otherwise glabrous.

The following are the main types of pubescence:

1. *Minutely puberulent.* Hairs exceedingly short, fine, straight, erect to ascending, sparse or dense, 0.02–0.1 mm long, found occasionally in plants of *Ludwigia linearis*, *L. sphaerocarpa*, on fruits of *L. microcarpa*, and less commonly on fruits of *L. simpsonii*, *L. curtissii*, and *L. suffruticosa*.

2. *Strigillose.* Hairs coarse, translucent, unicellular, 0.1–0.6 mm long, appressed to ascending; found in some populations of *Ludwigia sphaerocarpa* and *L. linearis*.

3. *Minutely strigillose.* Similar to strigillose pubescence, but the hairs more slender and shorter, ranging from 0.02 to 0.1 mm long. Frequently seen on sepals, bracteoles, and leaves of various species; also on the wings of capsules in *Ludwigia lanceolata* and capsules of both subspecies of *L. glandulosa*, and occasionally of *L. polycarpa*.

4. *Minutely papillose.* Blunt-tipped, minute projections from the surface, ca. 0.02–0.03 mm in length. This hair type is found occasionally on the margins of leaves and sepals, on fruit walls, and on nectary discs. It may be difficult to distinguish from minutely strigillose hair when the latter is exceedingly short.

5. *Hirtellous.* Hairs coarse, stiff, straight, erect to spreading, with an attenuate apex and a slightly broadened base, 0.25–0.95 mm long, translucent or spotted with light brown pigments. Hairs of this type are typical of *Ludwigia pilosa*, *L. ravenii*, and occasionally of *L. sphaerocarpa*, as well as part of the plant body of *L. suffruticosa*.

LEAVES

The leaves are simple and alternate. *Ludwigia simpsonii* is exceptional in frequently having some opposite or subopposite leaves at the lower nodes or in the seedling stage, a feature that might be related to the derivation of one or more of its genomes from plants of the opposite-leaved sect. *Dantia* (see below). The leaves on the rhizomes of *L. suffruticosa* are small and scalelike. Those on stolons are mostly elliptic- to rhombic-obovate or suborbicular (narrowly elliptic to narrowly oblanceolate in *L. linearis* and *L. linifolia*). These are usually broader and shorter than the cauline leaves, which are usually narrowly lanceolate to lanceolate, occasionally elliptic or oblanceolate, and often gradually reduced and narrower up the stem. *Ludwigia linearis* and *L. linifolia* have sublinear leaves. In *L. curtissii*, *L. microcarpa*, and *L. simpsonii*, the leaves range from (narrowly) spatulate-oblanceolate to spatulate-obovate or spatulate.

The leaves of all species of sect. *Microcarpium* are sessile or nearly so and either narrowly cuneate or attenuate basally. *Ludwigia suffruticosa* is exceptional in having a rounded to obtuse leaf base.

As in *Ludwigia* sect. *Myrtocarpus* sensu lato (Ramamoorthy & Zardini, 1987), the leaf margin is usually subentire, with a few glandular reddish or pink teeth that have an unusual hydathodal structure (Castells et al., 1979; Keating, 1982); such teeth are especially evident in *L. microcarpa*.

The secondary veins of leaves are usually obscure adaxially and distinct abaxially in sect. *Microcarpium*. In the closely allied *Ludwigia linifolia* and *L. stricta* and in *L. simpsonii* and *L. curtissii*, the secondary veins are, however, faint on both sides of the leaves. *Ludwigia linearis*, having narrow leaves like the related *L. linifolia*, has, by contrast, on its abaxial leaf surface very evident secondary veins, which anastomose and form a pair of marginal veins along the margins.

INFLORESCENCE

The flowers are sessile or shortly pedicellate and borne singly in the (usually upper) leaf axils of the main stem and the branches. In *Ludwigia suffruticosa*, the flowers are congested in very compact terminal spikes or racemes. The leaves subtending the flowers are much reduced and bractlike. As stems of this species remain single or have only a few branches, there are only one to several such inflorescences per plant. In most other species, the stems are well branched, and the flowers are axillary and usually very abundant. In *L. alata* and *L. pilosa*, the flowers are sometimes quite congested on the upper parts of branches. In *L. polycarpa* and *L. glandulosa*, one to a few very short branches heavily laden with flowers/fruits are often seen from the very base of primary branches. This frequently gives an appearance of several flowering branches arising simultaneously from the nodes of the main stem.

PEDICELS

The flowers and fruits are nearly sessile in most species. Pedicels (measured from the base of mature fruits), when present, are usually up to 0.5 (–1) mm long. Pedicels of *Ludwigia suffruticosa* and *L. sphaerocarpa* range 0.5–1.5(–2.3) mm long. Populations of *L. linearis* from west of the Mississippi River often have distinct pedicels up to 3.5(–5) mm long.

BRACTEOLES

Bracteoles are present in pairs near the base of the ovary in all species. They are succulent and are flanked by a pair of reddish or dark purplish, glandlike stipels on their base. A small swollen emergence located immediately below the bracteole is apparently an extension of the bracteole base and is prominent in some species, especially *Ludwigia curtissii*, *L. lanceolata*, *L. microcarpa*, and *L. simpsonii*. This character is more evident in live plants than in herbarium specimens.

Despite often being variable in length, even within the same plant (in *Ludwigia linifolia*, the bracteoles range (1.5–)2.5–9(–13) mm long), a few species, including *L. glandulosa*, *L. microcarpa*, and *L. sphaerocarpa*, consistently have shorter bracteoles (less than 1.5 mm long) than those of the other species (Table 2). The bracteoles are located either at the base or higher up on the sides of the capsules. In *L. sphaerocarpa* and occasionally in *L. glandulosa*, *L. linearis*, and *L. suffruticosa*, however, the bracteoles are found on the short pedicels.

FLOWERS

Of the 15 taxa of sect. *Microcarpium*, only three diploid species are petaliferous, although vestigial petals may occasionally appear in a few flowers of polyploid species (Table 2). Flowers are consistently tetramerous, pentamerous flowers being exceptional.

SEPALS

Sepals are entire, but may be minutely strigillose along the margins in some species. Unlike plants of sect. *Myrtocarpus* sensu lato (Ramamoorthy & Zardini, 1987), the sepals persist even after the capsules mature and dehisce. Sepals are greenish in most species, but they are creamy white on the adaxial surface in *L. alata*, *L. pilosa*, and *L. suffruticosa* and are yellowish on the adaxial surface in *L. sphaerocarpa*.

PETALS

Petals are yellow, small, narrowly obovate to subrotund, and range from 2.5 to 6 mm long and from 1.2 to 5 mm wide. They fall off a few hours after anthesis, which occurs early in the morning, and are usually gone by noon. All petaliferous species are able to effect mechanical self-pollination. My field experience, however, did not allow me to judge whether these plants attract significantly more insect pollinators than other apetalous species with showy sepals.

STAMENS

Most species of *Ludwigia* are consistently either haplostemonous (stamens in one whorl) or diplostemonous (stamens in two whorls) (Ramamoorthy & Zardini, 1987). All species of sect. *Microcarpium* are haplostemonous, which is a derived condition. The stamens are antesepalous, situated between the sepal base and the nectary discs.

ANTHERS

The anthers vary from 0.1 mm long in *Ludwigia microcarpa* to 2 mm long in *L. linearis*. *Ludwigia linearis* is unique in sect. *Microcarpium* in having polysporangiate anthers partitioned horizontally by septa that include both tapetum and parenchyma (Tobe & Raven, 1986). Such specialization is shared only by *L. latifolia*, an unrelated South American species of sect. *Tectiflora*, and five other genera of Onagreae. It is worth noting, however, that these septa in the anthers disintegrate and result in a continuous sporogenous tissue before the anthers dehisce. Many conspicuous vestiges of the disintegrated septa are visible on the inner surface of the anther wall at this stage.

POLLEN

The pollen of *Ludwigia* sect. *Microcarpium* is quite uniform, being characterized by isopolar grains frequently with prominent colpal extensions and with a psilate exine (Praglowski et al., 1983). Five species of sect. *Microcarpium*—*L. alata*, *L. curtissii*, *L. microcarpa*, *L. simpsonii*, and *L. suffruticosa*—shed their pollen singly, whereas the other nine species shed their pollen in tetrads (Table 2). This character is of some taxonomic value. For example, it can be used along with seed-surface pattern to distinguish *L. alata*, which sheds its pollen singly, from *L. lanceolata*, which sheds its pollen as tetrads. These two species are similar in general aspect and in their obpyramidal, winged

TABLE 2. Diagnostic characters of species and subspecies of *Ludwigia* sect. *Microcarpium*.

Taxon with Chromosome Number	Petals Present (+) or Absent (−)	Pollen Grains Shed Singly (S) or as Tetrads (T)	Overall Pubescence	Capsule Length (mm)	Capsule Shape	Bracteole Length (mm)	Seed Surface Cell Shape and Orientation[1]
L. linifolia, $n = 8$	+	T	Glabrous	6–12	Subcylindric	(1.5)3–10(–13)	I
L. sticta, $n = 8$	+	T	Glabrous	5–6.5	Subcylindric	1–2.5	I
L. linearis, $n = 8$	+	T	Glabrous to densely strigillose	6–10	Elongate-obpyramidal	0.5–2.5	P or T[4]
L. glandulosa subsp. *glandulosa*, $n = 16$	−	T	Glabrous but sparsely strigillose on stem and fruit	(4–)5–8	Subcylindric	0.5–1.2	P
subsp. *brachycarpa*, $n = 16$	−	T	Glabrous, but strigillose on stem and fruit	2–4	Subcylindric	0.4–0.8	T
L. polycarpa, $n = 16$	−	T	Glabrous	(4–)4.5–7	Oblong-obovoid	3.5–7.5	P
L. suffruticosa, $n = 16$	−	S	Glabrous except the inflorescence and stem base, which are sparsely hirtellous	3.5–4	Obpyramidal with rounded corners	(3–)4–5.5(–6.5)	I
L. lanceolata, $n = 16$	−	T	Glabrous	(3.5–)4–5	Obpyramidal, 4-winged	1.5–4.3	I
L. alata, $n = 24$	−	S	Glabrous	3–4	Obpyramidal, 4-winged	2.5–4.5	T
L. sphaerocarpa, $n = 16$	−	T	Glabrous to densely strigillose	2–4.5	Subglobose	0.5–1.5(–2.5)	P and T[3]
L. pilosa, $n = 16$	−	T	Hirtellous	(3–)3.5–5	Subglobose to oblong-obovoid	2.5–7.2	I
L. ravenii, $n = 16$	−	T	Hirtellous	(3–)4–5.3	Oblong-obovoid	(1.5–)2–4.3	T
L. microcarpa, $n = 8$	−	S	Glabrous	1–1.5	Obpyramidal with rounded corners	0.3–1(–1.5)	T
L. simpsonii, $n = 24$	−	S	Glabrous	1.5–2(–2.5)	Broadly turbinate	1–2.5	T
L. curtisii, $n = 32$	−[2]	S	Glabrous	(2–)2.5–4.5	Turbinate	1.5–4.5	T

[1] Letter codes I, P, and T indicate seeds with surface cells more or less isodiametric (I), in columns elongate parallel to the seed length (P), and elongate transversely to the seed length (T).

[2] Flowers with 1–3(–4) vestigial petals sometimes observed.

[3] Seed surface cells elongate parallel to the seed length are predominantly exhibited by more glabrous populations, whereas cells elongate transversely to the seed length are prevalent in more strigillose populations.

[4] Seed surface shows a mixture of cells elongate parallel or transversely to the seed length. Sometimes the orientation of these columnar cells is irregular.

fruits, and are superficially difficult to separate. The mode in which pollen is shed is useful to detect natural hybrids when their putative parents differ in this respect. Such hybrids generally exhibit both modes of pollen dispersal or pollen in very loose tetrads. Finally, the percentage of stainable pollen is useful to detect sterile hybrids or hybrids with reduced fecundity.

DISCS

One of the important characters that allows *Ludwigia* to be recognized as the sister group to all other genera of Onagraceae is that its nectary disc is situated on the summit of the ovary. By contrast, all other onagraceous plants have nectaries at the base of the floral tube; the nectaries, therefore, are androecial (Eyde, 1981).

The discs of *Ludwigia* sect. *Microcarpium* are shallowly dome-shaped, and they occur on the apex of the ovary. They are more or less distinctly four-lobed, the lobes alternating with the stamens, and are antepetalous (in petalous species). They are usually yellow or greenish at anthesis and turn dark reddish purple in fruit. In most species the discs are glabrous. *Ludwigia pilosa* is, however, usually hirtellous around the style base and between the disc lobes. Plants of *L. sphaerocarpa* are sometimes hirtellous between the disc lobes, too. In densely strigillose populations of *L. linearis*, the nectary discs tend to be strigillose throughout or between the lobes also. In *L. linifolia* and *L. stricta*, the disc lobes are minutely papillose throughout, as are their fruit and seed surfaces.

CAPSULES

Characters of the capsules have been very useful to systematic and phylogenetic studies in *Ludwigia* (Small, 1933; Munz, 1942, 1944; Raven, 1963; Eyde, 1978; Ramamoorthy & Zardini, 1987). When Small (1933) first grouped plants of *Ludwigia* sect. *Microcarpium* (as "Microcarpeae"), the mode of capsular dehiscence was one of the main criteria. Although his observations on capsular dehiscence were incomplete and not all species in this group have capsules dehiscing by the separation of flaps from the top of the nectary disc (see below), his concept was taken up by Munz (1944, 1965) who formally described and established sect. *Microcarpium*.

The shape, size, and pubescence of capsules are very diverse within sect. *Microcarpium* (Table 2, Figs. 1–15). Capsule shape ranges from obpyramidal to subcylindric, oblong-obovate, turbinate, or subglobose, and size ranges from 1 mm long in *Ludwigia microcarpa* to 12 mm long in *L. linearis* and *L. linifolia*. The surface vestiture ranges from glabrous to minutely papillose, strigillose, or hirtellous. These characters have been extremely useful for identifying species and natural hybrids.

Furthermore, in *Ludwigia* sect. *Microcarpium*, three patterns of capsular dehiscence are recognized (Peng & Tobe, 1987), each of which has a distinct anatomical basis:

Ring dehiscence. The capsule dehisces along an apical "ring" as a result of the disintegration of thin-walled cells located between the nectary disc and the sepal base (Fig. 16). This pattern is exhibited by *Ludwigia alata*, *L. lanceolata*, *L. linearis*, *L. microcarpa*, and *L. suffruticosa*. It was previously thought of as the only way capsules of *Ludwigia* sect. *Microcarpium* dehisced (Small, 1933; Munz, 1944; Raven, 1963). In these plants

the zonation pattern in the capsule wall is relatively simple, consisting of the outer, enlarged parenchymatous exocarp and the inner spongy endocarp.

Peeled dehiscence. The capsule dehisces by the irregular rupture of the outer capsule wall (Fig. 17). This is exhibited by *Ludwigia glandulosa*, *L. linifolia*, *L. pilosa*, *L. polycarpa*, *L. ravenii*, *L. sphaerocarpa*, and *L. stricta*. These plants have a spongy mesocarp and an endocarp with conspicuous inner hypodermis. When the seeds are dispersed, they often carry along many hypodermal cells. Whether these cells are useful for the seeds to float awaits confirmation.

Loculicidal dehiscence. The capsule dehisces by initially forming four longitudinally lenticular slits opposite each of the loculi (Fig. 18). Eventually the capsule is split into four basally united parts. This type of dehiscence is seen only in the closely related polyploids *Ludwigia curtissii* and *L. simpsonii*. In these species, the zonation pattern of the fruit wall is basically similar to that of the "ring-dehiscent" species, except that the exocarp consists only of the outer epidermis and a single-celled layer of outer hypodermis compactly aligned beneath. These hypodermal cells are remarkably enlarged and radially elongate except along the median longitudinal line facing each locule, where they are abruptly reduced or replaced by small, parenchyma cells. It is exactly along these four lines that the capsules dehisce at maturity.

To summarize, the fruit wall of all species of *Ludwigia* sect. *Microcarpium* is differentiated into a spongy zone (endocarp in ring-dehiscent and loculicidally dehiscent species, or mesocarp in peeled-dehiscent species) and a continuous zone. As Eyde (1978) suggested, such differentiation undoubtedly aids seed dispersal by reducing the effective thickness and by the differential growth rate that could result in the separation of the outer layers from the inner. The specialized hypodermis in *L. curtissii* and *L. simpsonii* appears to represent a condition that has evolved a step beyond this point.

SEEDS

In all species of sect. *Microcarpium*, seeds have a narrow raphe and are free and pluriseriate in each locule of the capsule, with a narrow raphe. The seeds are small, from 0.4 to 0.7 mm long, and are cylindric, ellipsoid, reniform, or ovoid. They are mostly yellowish, light brown, or brown in color, although three species, *Ludwigia linifolia*, *L. microcarpa*, and *L. stricta*, nearly always have dark reddish seeds.

Eyde (1978) was the first to point out that species of sect. *Microcarpium* are remarkably diverse in surface cell orientation. Like capsule morphology, or rather together with capsule morphology, seed surface pattern provides excellent diagnostic characters for identifying the species and detecting natural hybrids. The seed surface cells are either subisodiametric or are elongate parallel or elongate transversely to the seed length, with minor variation on the two ends and areas near the raphe (Figs. 19–34). Although in different populations of both *L. glandulosa* and *L. linearis* the seed surface cells are oriented in two different ways, the pattern is not random. In *L. glandulosa*, the cells are elongate parallel to the seed length in subsp. *glandulosa* (Fig. 23) and transversely elongate in the western, short-fruited subsp. *brachycarpa* (Fig. 24). Plants of *L. linearis* are extremely variable in pubescence, ranging from completely glabrous to densely strigillose. In general, seed surface pattern seems to be correlated with pubescence: subglabrous plants usually exhibit cells elongate parallel to the seed length (Fig. 21), whereas densely strigillose individuals generally have seed surface cells elongate transversely to the seed length (Fig. 22).

In *Ludwigia sphaerocarpa* the seed surface cells (Fig. 29) are not as regularly oriented as they are in the other species. They are arranged in columns both transversely elongate and parallel to the seed length, with the former alignment often dominant in the central part of the seed. Some

seeds of this species have variously oriented cells, a pattern that supports the suggestion of a hybrid origin for *L. sphaerocarpa* (see below).

Reproductive Biology

All 14 species in *Ludwigia* sect. *Microcarpium* are genetically self-compatible perennials that reproduce sexually and vegetatively. About two-thirds of them are modally autogamous—a statistic comparable to that for the whole genus (Raven, 1979). Shortly after the flowers open in the morning, the stigma becomes sticky and receptive and the stamens dehisce, exposing yellowish pollen entangled by the viscin threads. Initially the stamens are held away from the stigma and spread apart. The filaments, however, gradually arch toward the center and finally the anthers become firmly appressed to the sides of the sticky stigma in one to several hours (usually before noon), thus effecting self-pollination. This occurs in petaliferous as well as apetalous species, with the exceptions discussed in the following paragraph.

In *Ludwigia alata*, *L. pilosa*, *L. suffruticosa*, and many individuals of *L. sphaerocarpa*, the anthers also bend toward the stigma at late anthesis, but the distance between the androecium and the gynoecium is such that self-pollination is impossible without the intervention of a pollen vector. In the first three, apetalous, species the sepals are conspicuous and creamy within; in *L. pilosa* they are often tinged with pink along the main veins and the edges. Presumably these petaloid sepals serve to attract insect pollinators. In addition, these three species have yellowish discs that produce abundant nectar. *Ludwigia sphaerocarpa*, by contrast, has sepals that are yellowish within and very bright yellow discs that are more conspicuous than those of any other species, with the possible exception of *L. linifolia* (see below). Outcrossing in all four above-mentioned species is therefore not reinforced by protogyny/protandry or by male sterility, but merely by the physical separation of the stigma and the anthers. The self-incompatibility found in the more primitive members of *Ludwigia* sect. *Myrtocarpus* sensu lato is not present in sect. *Microcarpium*.

Nectary discs are present in all species in sect. *Microcarpium*, but they vary in size and in the quantity of nectar produced. *Ludwigia microcarpa*, an apetalous species with tiny flowers (the ovary is less than 1 mm long), has a nearly flat, greenish disc that produces very little nectar, and is presumably highly autogamous. Despite this, the fact that several natural hybrids—e.g., *L. microcarpa* × *L. curtissii* and *L. microcarpa* × *L. simpsonii*, and an intersectional hybrid, *L. microcarpa* × *L. palustris* ($n = 8$; sect. *Dantia*)—were collected in the field where the parental species grow sympatrically (see below) suggests that insect pollinators do occasionally visit plants with minute, inconspicuous flowers.

Living plants from two of the three petaliferous species were available for observation; *Ludwigia stricta*, endemic in Cuba, has not been studied as a living plant. Flowers of *L. linifolia* have very conspicuous nectary discs that produce copious nectar. This, along with the yellow petals, serves to make the flowers highly attractive to insects. *Ludwigia linearis* has a comparatively shallow ovary disc that secretes less nectar. This species is noteworthy in sharing with the unrelated South American *L. latifolia* (Benth.) Hara (sect. *Tectiflora*) the distinction of being the only members of the genus *Ludwigia* in which the sporogenous tissue of the anthers is divided into packets horizontally by both tapetum and parenchyma (Eyde, 1977; Tobe & Raven, 1986). This character is also shared by five other genera of Onagraceae, as mentioned previously.

Paper wasps of the genus *Polistes* have been observed to visit flowers of species of *Ludwigia* sect. *Microcarpium* grown in the netted experimental greenhouse at the Missouri Botanical Garden. In the field, more insects (usually bumblebees, honeybees, and wasps) were attracted to *L. pilosa* and, less so, to *L. sphaerocarpa*. Moths and ants have also been observed visiting *L. pilosa*. Relatively few field observations of insect pollinations on other species have been made in my trips to the southeastern United States. Circumstantial evidence from the presence of abundant natural hybrid populations suggests that insect pollination must be more common than I have observed.

In addition to sexual reproduction, nearly all species of *Ludwigia* sect. *Microcarpium* produce sprawling stolons at the base of the erect, flowering stems late in their flowering season. This vegetative reproduction enables the plants to overwinter, when the erect stems die back; in spring, they can then produce a large colony before other species can invade. Some of the sterile populations of natural hybrids also persist by this means. In *L. suffruticosa*, however, stolons are not as common as underground rhizomes. In *L. curtissii* and *L. simpsonii*, stolons are not apparent. These plants simply form new shoots from the lower nodes of the died-back stem of the previous year. These shoots are decumbent or ascending initially, but soon become erect.

Cytology

Chromosomes of *Ludwigia* are the smallest in the Onagraceae, and they may differ conspicuously in size within a single genome. The proximal ends of the chromosomes are heavily pycnotic and appear in interphase nuclei as very distinct and definite chromocenters (Kurabayashi et al., 1962). The basic chromosome number of the genus is $x = 8$, with no aneuploidy but extensive polyploidy (Raven & Tai, 1979). Through the efforts of Gregory & Klein (1960), Kurabayashi et al. (1962), Raven & Tai (1979), and Peng (1984, 1988), the chromosome numbers of all species of *Ludwigia* sect. *Microcarpium* have been established. There are four diploid species with $n = 8$ (*L. linearis*, *L. linifolia*, *L. microcarpa*, and *L. stricta*), eight tetraploid taxa with $n = 16$ (*L. glandulosa* subsp. *glandulosa*, *L. glandulosa* subsp. *brachycarpa*, *L. lanceolata*, *L. pilosa*, *L. polycarpa*, *L. ravenii*, *L. sphaerocarpa*, and *L. suffruticosa*), two hexaploid members with $n = 24$ (*L. alata* and *L. simpsonii*), and an octoploid with $n = 32$ (*L. curtissii*). For a review and discussions see Peng (1988).

Ecology and Geographical Distribution

With the exceptions of *Ludwigia stricta*, which is endemic to Cuba, and *L. polycarpa*, which is distributed mainly in the northcentral United States, *Ludwigia* sect. *Microcarpium* is confined primarily to the Coastal Plain of the southeastern United States. Several species also extend further south or east: *L. alata* to Jamaica; *L. curtissii* to the Bahamas; and *L. linifolia* disjunct to Tabasco, Mexico. *Ludwigia simpsonii* occurs in Cuba and Jamaica, and *L. microcarpa* in the Bahamas, Cuba, and Jamaica. *Ludwigia stricta* is exceptional in being endemic to Cuba. A detailed description of the ranges with maps for each species is given in the taxonomic treatment.

Like *Ludwigia* species occurring in other parts of the world, plants of *Ludwigia* sect. *Microcarpium* grow in wet habitats. They are commonly found along alluvial ground or in the shallow water of many areas, including ponds, lakes, rivers, streams, lagoons, sloughs, backwaters, swales, wet meadows or prairies, open swamp forests, drainages, and irrigation ditches. All species grow in sandy or occasionally peaty soils. A few species grow in brackish marsh or tidal flats (*L. alata*, *L. linifolia*, *L. microcarpa*, and *L. simpsonii*), in sinks in limestone prairies (*L. alata*, *L. curtissii*, *L. microcarpa*, *L. simpsonii*, *L. sphaerocarpa*, and *L. suffruticosa*), and in clay soils (both subspecies of *L. glandulosa*). None of the species in *Ludwigia* sect. *Microcarpium* exhibit the aggressiveness characteristic of weedy plants, although the following taxa have rarely been observed growing in disturbed habitats: *L. linearis*, *L. microcarpa*, *L. simpsonii*, and both subspecies of *L. glandulosa*.

Experimental Hybridization

Results from the extensive artificial hybridization among members of *Ludwigia* sect. *Microcarpium* (Peng, 1988) are summarized as follows.

1. There is generally little difficulty in obtaining hybrids between members of sect. *Microcarpium*; most F_1 plants grow to maturity, and many set abundant seeds. Hybrids between plants of the same ploidy level are generally intermediate in morphology; hybrids between plants of different ploidy levels tend to be more similar to the parent with the higher chromosome number. Character such as capsule shape and size, bracteole length, overall pubescence, presence or absence of petals, seed surface pattern, and pollen stainability are very useful in distinguishing species and identifying hybrids.
2. All diploid species can be crossed with one another and form floriferous F_1 plants. Hybrids between the petaliferous diploids with narrow leaves (*Ludwigia linearis* and *L. linifolia*) are vigorous, have ca. 50% stainable pollen, and produce a moderate amount of viable seeds. A modal meiotic configuration of a ring or chain of four plus six bivalents are frequently observed in reciprocal F_1 hybrids. Hybrids between either of the petaliferous diploids and the apetalous, diploid *L. microcarpa* are, in contrast, highly sterile as to pollen and seed set. Nearly all chromosomes remain unpaired in meiosis in these hybrids.
3. All eight tetraploid members studied are interfertile: chromosome pairing in meiosis is nearly complete, and pollen stainability and seed set are high in hybrids between any two tetraploid species, no matter how different they are from each other morphologically.
4. Although the two hexaploid ($n = 24$) species, *Ludwigia alata* and *L. simpsonii*, can be crossed and produce healthy F_1s, meiosis is irregular with abundant unpaired chromosomes. The affinity of *L. alata* is apparently with species of the tetraploid group, based on morphological characters. Hybrids between *L. alata* and any tetraploid species are easily obtained. They produce moderate seed set and have 43–71% stainable pollen. Meiosis in these F_1 individuals

typically exhibited a maximum of 16 bivalents and eight unpaired chromosomes. By contrast, the hexaploid *Ludwigia simpsonii* ($n = 24$) is clearly allied to the octoploid *L. curtissii* ($n = 32$). Hybrids between them are highly fertile, having 80–90% stainable pollen and producing good seed set. These plants consistently exhibited a meiotic configuration of 24 bivalents and eight unpaired chromosomes.

5. Seeds obtained from crossing species of any two of the following groups, (1) tetraploid species group (including the allied *Ludwigia alata*), (2) diploid species, and (3) *L. curtissii* and *L. simpsonii*, often failed to germinate. Those that germinate may either be inviable or produce flowers that set negligible or no seed and tend to have very low levels of stainable pollen. For a complete discussion of the experimental hybrids, consult Peng (1988).

Natural Hybridization

Experimental hybridization (Peng, 1988) revealed that vigorous and floriferous hybrids can readily be obtained between most members of *Ludwigia* sect. *Microcarpium*. The general lack of postzygotic barriers and the facts that all species in this section are perennial and that most of them are sympatric, have similar preference for habitats, flower in the morning during the same season, are facultatively outcrossing, and have similar kinds of indiscriminate insect pollinators, strongly suggest that natural hybrids should be fairly common in the field.

Field observations and herbarium study show that hybrid populations of *Ludwigia* sect. *Microcarpium* are indeed abundant. Except for this and the companion paper (Peng, 1988), however, very little has been reported about the natural hybrid populations of sect. *Microcarpium*. The variation patterns generated by the intergradation among some members of sect. *Microcarpium* have previously been detected by Torrey & Gray (1840) and Small (1903); such plants were given names at varietal and specific rank respectively, but no indication of their hybrid origins was mentioned. Torrey & Gray (1840) described *L. capitata β pubens* from a population of *L. suffruticosa* × *L. pilosa* from Georgia; Small (1903) applied the name *L. simulata* to a population of *L. pilosa* × *L. lanceolata* from North Carolina.

Duke (1955) was the first to point out that some *Ludwigia* species show varying degrees and patterns of intergradation in North Carolina. In his informative study, he compared the morphological characters of a mixed population consisting of plants of *L. pilosa*, *L. glandulosa*, and the intermediates, and considered the latter as possible hybrids. Upon examination of his voucher collections, it is confirmed beyond doubt that these plants represent uniform F_1 hybrids of *L. pilosa* × *L. glandulosa*. Duke (1955) further suggested that "self-pollination is the rule in this genus, and that cross-pollination is a very rare exception to the rule," and speculated that phyllophagous insect caterpillars may have brought about cross-pollination while foraging leaves. This, however, is not true, as at least four species in sect. *Microcarpium* have somewhat showy sepals and produce copious nectar and require insect vectors to pollinate their flowers to set seeds. Such insects as bumblebees, wasps, honeybees, moths, and even ants have frequently been seen obtaining nectar on the flowers of *Ludwigia* sect. *Microcarpium*.

In a biosystematic study of *Ludwigia* sect. *Dantia*, a close ally of sect. *Microcarpium* with opposite leaves and prostrate habit, Schmidt (1967) reported two intersectional hybrids, *L. repens* × *L. simpsonii* (as *L. repens* × *L. curtissii*) and *L. palustris* × *L. glandulosa* from North Carolina and Florida, respectively. His observations of the hybrid between *L. palustris* ($n = 8$; sect. *Dantia*) and *L. glandulosa* ($n = 16$; sect. *Microcarpium*) revealed very little association between chromosomes, with 0–3 weakly joined bivalents in meiosis. The other natural hybrid, involving *L. repens* ($n = 24$; sect. *Dantia*) and *L. simpsonii* ($n = 24$; sect. *Microcarpium*), yielded 48 unpaired chromosomes at mesiosis, suggesting the dissimilarity in the genomes of plants in the two North American sections.

Observation of individuals exhibiting a combination of characters intermediate between distinct taxa initially suggests natural hybridization. Members of the following species pairs, *Ludwigia alata* ($n = 24$) and *L. lanceolata* ($n = 16$), *L. pilosa* ($n = 16$) and *L. ravenii* ($n = 16$), and *L. simpsonii* ($n = 24$) and *L. curtissii* ($n = 32$), however, are usually so similar in appearance, especially in dried herbarium specimens, that their hybrids cannot be recognized readily.

Results from experimental hybridization suggest that capsule shape and size are the most important diagnostic characters for detecting hybrids in sect. *Microcarpium*. Other useful features include overall pubescence, seed surface cell shape and orientation, the presence or absence of petals, whether pollen grains are shed singly vs. in tetrads, and pollen stainability. Seed surface pattern is useful only for the determination of hybrids in the tet-

raploid group (including *Ludwigia alata*), as these nine taxa are interfertile, yield abundant seeds, and are diverse with respect to this character. Absence of developing fruits and low levels of pollen stainability, however, are characteristic of hybrids resulting from all other heteroploid crosses, with the exception of *L. curtissii* ($n = 32$) × *L. simpsonii* ($n = 24$). As a last resort, chromosome number and meiotic chromosome behavior are useful indicators of natural hybrids when the parents involved have different chromosome numbers or differentiated genomes.

The natural hybrid populations mentioned below are discussed individually following the treatment of the species in the systematic section. Full citation of these specimens of hybrids is given in the companion paper (Peng, 1988).

Field experience indicates that natural hybrid populations are fairly common wherever two or more species grow side by side. A total of 15 intrasectional hybrids and seven intersectional (among plants of sects. *Microcarpium* and *Dantia*) hybrids are recognized (Peng, 1988). Hybrids resulting from crosses among members of the tetraploid species group (including *Ludwigia alata*) are by far the most common. The following hybrid combinations are representative: *L. alata* × *L. pilosa* (four populations from Florida, one from Georgia, and one from Mississippi), *L. alata* × *L. suffruticosa* (seven populations from Florida), *L. glandulosa* subsp. *glandulosa* × *L. glandulosa* subsp. *brachycarpa* (one from Oklahoma and one from Texas), *L. glandulosa* subsp. *glandulosa* × *L. pilosa* (two from North Carolina, one from Georgia, one from Alabama, and two from Mississippi), *L. glandulosa* subsp. *glandulosa* × *L. sphaerocarpa* (one from South Carolina, one from Missouri), *L. lanceolata* × *L. pilosa* (three populations from Florida), *L. lanceolata* × *L. suffruticosa* (two from Florida), *L. pilosa* × *L. sphaerocarpa* (many populations from North Carolina, South Carolina, Georgia, Florida, Alabama, and Texas), *L. pilosa* × *L. suffruticosa* (two from North Carolina, three from Georgia, and two from Florida), and *L. polycarpa* × *L. sphaerocarpa* (two populations from Indiana). Backcrossed generations or segregates of advanced generations are found of *L. lanceolata* × *L. suffruticosa*, *L. pilosa* × *L. suffruticosa*, and most abundantly of *L. pilosa* × *L. sphaerocarpa*.

As in the case of artificial hybridization, the tetraploid hybrids are highly fertile as to seed and pollen; hybrids between the hexaploid *Ludwigia alata* and the tetraploid species have slightly lower levels of stainable pollen and seed set. It is noteworthy that in nearly all of the above hybrids at least one member of each pair of putative parents is unable to undergo mechanical self-pollination and has somewhat showy sepals. In other words, *L. alata*, *L. pilosa*, *L. sphaerocarpa*, and *L. suffruticosa* hybridize more frequently than other tetraploid species that are modally autogamous.

Sporadic occurrence of sterile triploid hybrids include *Ludwigia glandulosa* ($n = 16$) × *L. linearis* ($n = 8$) (one population from North Carolina and the other from Georgia) and *L. sphaerocarpa* ($n = 16$) × *L. linearis* (one population from Alabama). One probably diploid hybrid population of *L. linearis* × *L. linifolia* was collected from Florida in 1981. Attempts to re-collect and to study live plants of this hybrid have failed, because the habitat was destroyed (Popenoe, pers. comm.).

Hybrids between *Ludwigia curtissii* ($n = 32$) and *L. simpsonii* ($n = 24$) very probably occur in the field but would be difficult to detect. *Ludwigia curtissii* hybridizes with *L. linifolia* ($n = 8$) and with *L. microcarpa* ($n = 8$) to form sterile hybrids. At least four populations of *L. simpsonii* × *L. microcarpa* are known from Florida. It is of interest to note that among the putative parental species here concerned, only *L. linifolia* has somewhat showy petals and produces copious nectar, whereas all other species are probably modally autogamous.

Hybrids involving putative parents from sect. *Microcarpium* and sect. *Dantia* are also not uncommon. *Ludwigia repens* ($n = 24$; sect. *Dantia*) hybridizes with *L. simpsonii* ($n = 24$) and *L. curtissii* ($n = 32$) in Florida. At least eight such populations are known, all producing flowers, but the ovaries abort after mechanical self-pollination. *Ludwigia palustris* ($n = 8$; sect. *Dantia*), a widespread and apparently autogamous species, hybridizes with *L. glandulosa* subsp. *glandulosa* ($n = 16$) and forms sterile hybrid populations in Virginia (one population). It also hybridizes with the diploid, small-flowered and presumably autogamous *L. microcarpa* of sect. *Microcarpium* and forms sterile hybrids in North Carolina (one population), Georgia (one population), and Florida (three populations). In Kentucky, *L. palustris* hybridizes with *L. polycarpa* ($n = 16$) and likewise forms sterile hybrids.

The only intersectional tetraploid hybrid is known from a single population of *Ludwigia arcuata* ($n = 16$; sect. *Dantia*) × *L. pilosa* ($n = 16$) collected from Alabama. Flowers of both putative parents are showy and attract many insect pollinators. Established hybrids, however, are very rare in nature. Although some seeds were observed in mature cap-

TABLE 3. Comparison of diploid petaliferous species in *Ludwigia* sect. *Microcarpium*.

Characters	*L. linearis*	*L. linifolia*	*L. stricta*
Plant height (cm)	(22–)50–100(–145)	12–55(–62)	10–60(–85)
Cauline leaves	Very narrowly elliptic to sublinear	Oblanceolate-linear to linear	Oblanceolate or elliptic to narrowly so
Abaxial marginal veins	Distinct	Obscure	Obscure
Sepal			
Length (mm)	2.3–5(–5.6)	(3.3–)4–7	(1.8–)2–3
Width (mm)	1–3(–3.5)	1.1–1.7	0.9–1.5
Length : width	1.5–2.5	3–4	2
Anther length (mm)	1–2	0.65–1.1	0.5–0.7
Septa in anther sac	Present	Lacking	Lacking
Filament length (mm)	1.1–2(–2.2)	(1.3–)1.5–2.5(–3)	0.75–1.1
Style length (mm)	(0.4–)0.7–1.5	1.25–2.5	0.55–0.9
Stigma			
Shape	Cylindric	Depressed globose	Depressed globose
Length	(0.6–)1–1.9	0.3–0.6	0.25–0.5
Nectary disc	Shallow	Very prominent	Prominent
Capsule			
Shape	Elongate-obpyramidal	Subcylindrical	Subcylindrical
Surface	With a shallow, longitudinal groove on each side	Nearly smooth	Nearly smooth
Length (mm)	5–10(–12)	5–10(–12)	5–6(–7)
Thickness (mm)	2–5.5	1.3–2(–2.2)	1.6–1.8
Dehiscence	Ring-dehiscent from top	Peeling off from the sides	Peeling off from the sides
Bracteole length (mm)	0.4–4(–7.5)	(1.5–)2.5–9(–13)	0.7–2.5(–3)
Seed			
Color	Yellowish	Reddish brown	Reddish brown
Surface cell shape	Columnar	Subisodiametric	Subisodiametric

sules of the herbarium specimen (Mobile Co.: Audubon Bird Sanctuary, Dauphin Island, *Deramus 0643* [DS, UNA]), they are probably inviable. Such hybrids synthesized in the experimental greenhouse showed a remarkably high level of chromosome pairing (ca. 12–15 bivalents and 2–8 unpaired univalents; 1 or 2 trivalents occasionally seen) but had only 38% stainable pollen. Not a single seed was set despite many attempts at artificial self-pollination (like *L. pilosa*, this hybrid cannot undergo mechanical self-pollination).

To summarize, geographical isolation and self-pollination are the primary factors limiting natural hybridization among species of *Ludwigia* sect. *Microcarpium*. For example, *L. polycarpa* occurs in the central Midwest (Fig. 45), where it is isolated geographically from all other species of sect. *Microcarpium* except *L. sphaerocarpa*. Where the two species come into contact, hybridization occurs. *Ludwigia microcarpa*, an extreme selfer, has been hybridized successfully with most species of sect. *Microcarpium* in the greenhouse, and the resulting hybrids were vigorous. *Ludwigia microcarpa* grows sympatrically with many other species, but natural hybrids have been found only with *L. simpsonii*, *L. curtissii*, and some members of sect. *Dantia*.

In general, natural hybrids are usually frequent wherever two species occur together. This is particularly true for plants in the tetraploid group, hybrids of which were often found intermixed with putative parents. The sorts of disturbed habitats suggested by Anderson (1948) do not appear to be necessary for the establishment of natural hybrids in *Ludwigia* sect. *Microcarpium*.

As outlined above, natural hybridization is not limited to species within *Ludwigia* sect. *Microcarpium*. At least seven hybrid combinations, some of which occur commonly in nature, have been found between members of sect. *Microcarpium* and sect. *Dantia*. Most of these have also been synthesized in the experimental greenhouse. None

of the intersectional hybrids set viable seeds, although they are usually very vigorous and appear to compete well with their parents. Once established, these sterile hybrids may be able to persist in a given location due to their perennial habit. Furthermore, new colonies may be established vegetatively if entire plants or fragments are transported to suitable habitats, most likely by water.

Evolutionary Relationships

Ludwigia sect. *Microcarpium* consists of four diploids, eight tetraploids, two hexaploids, and one octoploid.

Ludwigia microcarpa is distinct among the diploid species by the more or less spatulate cauline leaves and small, inconspicuous, apetalous flowers; and it is modally self-pollinated. All three other diploid species, *L. linearis*, *L. linifolius*, and *L. stricta*, have elongate, narrow leaves and relatively showy, petaliferous flowers and are facultatively outcrossing. The divergence of *L. microcarpa* from the rest of the diploids is further demonstrated by the cytogenetic study of artificial hybrids in this group. Artificial F_1 hybrids between *L. microcarpa* and either *L. linearis* or *L. linifolia* were completely sterile; in meiosis they revealed very few chromosome associations, with 0–3 weakly joined bivalents.

Ludwigia linearis is unusual in sharing with the unrelated South American species *L. latifolia* (Benth.) Hara (sect. *Tectiflora*) the character of polysporangiate anthers in which the locules are divided by transverse septa composed of tapetum and parenchyma. Otherwise, *L. linearis* is apparently somewhat related to *L. linifolia*. The two species differ chromosomally by at least one reciprocal translocation. F_1 hybrids between them have ca. 50% stainable pollen, and they produce moderate quantities of viable seeds.

Ludwigia stricta, which is endemic to Cuba, is more closely related to *L. linifolia* than to any other species in sect. *Microcarpium*. It differs from *L. linifolia* only by the broader leaves, smaller floral parts, and shorter fruits (Table 3). The crossing relationships of *L. stricta* with other diploid species are currently being investigated.

The eight tetraploid taxa ($n = 16$) are uniformly apetalous and are otherwise remarkably diverse in overall pubescence, shape and color of sepals, shape and dehiscence of capsules, bracteole length, seed surface cell pattern, and whether pollen is shed singly or as tetrads. Correlations in these features, however, are evidently nonexistent. It is therefore of great interest to find that these eight morphologically well-delimited taxa can be crossed in any combination and produce vigorous and fertile offspring. The hybrids exhibit nearly complete chromosome pairing and high levels of stainable pollen. Natural hybridization among plants of this group is abundant, especially among those members with somewhat showy sepals. Most natural hybrids are F_1 plants that occur in more or less undisturbed habitats where the putative parents also grow. Introgressed populations or segregates of advanced generation of *Ludwigia pilosa* × *L. sphaerocarpa* hybrids, however, are also abundant and widespread. Cytogenetic studies of experimental hybrids between the tetraploid species and the diploid species suggest that no extant diploids are believed to have been involved directly in the formation of the tetraploid species group.

Ludwigia alata, a hexaploid ($n = 24$) species, resembles the tetraploids morphologically. Superficially it is most similar to *L. lanceolata* in general aspect and especially in the characters of winged capsules. Nearly all of the reciprocal hybrids between the hexaploid *L. alata* and any of the tetraploid species exhibited a modal meiotic configuration of 16 bivalents and 8 univalents, which suggests that they share two genomes in common. Judged from the morphology of the hexaploid and from the pairing of chromosomes in experimental hybrids, *L. alata* probably originated following hybridization between one of the tetraploids, perhaps *L. lanceolata*, and the diploid *L. microcarpa*, or populations ancestral to them.

The affinity of the other hexaploid, *Ludwigia simpsonii*, however, is definitely with *L. curtissii*, the only octoploid in sect. *Microcarpium*. These two species are unique in having loculicidal capsules and in having, along with the diploid *L. microcarpa*, more or less spatulate cauline leaves. *Ludwigia curtissii* and *L. simpsonii* are polymorphic and are sometimes difficult to distinguish morphologically. Cytogenetic data suggest that the hexaploid chromosome complement of *L. simpsonii* includes three different genomes, one of which is identical with that of *L. microcarpa*. Artificial hybrids between *L. simpsonii* and *L. curtissii* exhibited a meiotic configuration of 24 bivalents and eight univalents, which suggests that these two closely related species possess three genomes in common. Based on morphological characters and crossing relationships, the octoploid *L. curtissii* was probably derived following hybridization between a petaliferous, narrow-leaved diploid lineage similar to *L. linifolia* and the hexaploid *L. simpsonii*.

To summarize, following the differentiation of diploid species of *Ludwigia* sect. *Microcarpium*, some diploids have evidently become extinct. Natural hybridization among the diploid lineages fol-

lowed by polyploidy has played a major role in the evolution of this group. Postzygotic genetic barriers do not separate most of the species of this section. Rather, the major limiting factor to natural hybridization appears to be the modally autogamous breeding system of most species. Geographical isolation is important only with respect to *L. polycarpa*, which is distributed well to the north of nearly all the other taxa.

Natural hybridization is prevalent within *Ludwigia* sect. *Microcarpium*, and hybrids often grow intermixed with putative parental populations. All interploid hybrids are completely sterile except for crosses between *L. alata* ($n = 24$) and the tetraploid species ($n = 16$), and crosses between *L. curtissii* ($n = 32$) and *L. simpsonii* ($n = 24$). Even sterile hybrids, however, can persist and form large colonies, at least locally, by means of strong vegetative reproduction via stolons.

Natural hybrids are especially common among members of the tetraploid group (including *Ludwigia alata*) and are nearly always vigorous and fertile. Especially complex is the pattern of variation in the tetraploid *L. sphaerocarpa*, which is apparently comprised largely of widespread stabilized hybrid populations that exhibit a combination of characters distinguishing them from other taxa. As in the evolution of *Epilobium* in New Zealand (Raven & Raven, 1976), the recombination of genetic information from somewhat differentiated populations followed by the maintenance of well adapted genetic strains by a combination of autogamy and vegetative reproduction appears to have played a central role in the evolution of the polyploid members of *Ludwigia* sect. *Microcarpium*.

Systematic Treatment

Ludwigia sect. **Microcarpium** Munz, Bull. Torrey Bot. Club 71: 154. 1944; N. Am. Fl. ser. II, pt. 5: 42. 1965. Raven, Reinwardtia 6: 336. 1963. "*Microcarpeae*" Small, Man. S.E. Fl. 941. 1933. Type species: *Ludwigia pilosa* Walter.

Erect perennial herbs, perennating mostly by leafy, basal stolons (mainly by rhizomes in *Ludwigia suffruticosa*). Stems usually profusely branched except in *L. suffruticosa*, becoming swollen and spongy below when submerged. Leaves alternate, sessile or nearly so, subentire, usually with hydathodal glands along margins. Flowers sessile or shortly pedicellate, axillary (in very compact, short racemes or spikes in *L. suffruticosa*). Bracteoles in subopposite pairs attached from the base of the pedicel to halfway up the ovary. Flowers 4-merous, mostly apetalous (consistently with 4 petals in 3 diploid species). Sepals mostly greenish (creamy white or yellowish in 4 apetalous species). Stamens haplostemonous; anther sacs undivided except in *L. linearis*, in which the polysporangiate anthers are partitioned horizontally by tapetums and parenchyma. Pollen shed singly or as tetrads. Nectary disc 4-lobed, usually shallowly raised above ovary apex (flat in *L. microcarpa*). Capsules with ca. 10–700 seeds, obpyramidal to subcylindric, oblong-obovoid, turbinate, or subglobose, dehiscent by the separation of the disc and the ovary wall, or forming 4 longitudinally lenticular slits opposite each locule, or the irregular rupture of the outer wall. Seeds yellowish, light tan to reddish brown, free and pluriseriate in each locule, with a narrow raphe; surface cells suborbicular, elongate parallel to or perpendicular to the seed length. Self-compatible, modally autogamous in most species. Gametic chromosome number, $n = 8, 16, 24, 32$.

Distribution. Atlantic and Gulf Coastal Plain of the United States (*Ludwigia polycarpa* is exceptional by ranging into the northcentral United States), Bahamas, Cuba, Jamaica, and Tabasco, Mexico.

Key to the Species of *Ludwigia* Sect. *Microcarpium*

1a. Capsules elongate, at least twice as long as broad.
  2a. Petals absent; leaves narrowly elliptic ..... 4. *L. glandulosa*
  2b. Petals 4; leaves sublinear to linear.
    3a. Lateral and marginal veins on abaxial leaf surface distinct; capsules elongate-obpyramidal, ring-dehiscent on top; seeds yellowish; anthers 1–2 mm long, the sacs septate ..... 3. *L. linearis*
    3b. Lateral and marginal veins on abaxial leaf surface obscure; capsules subcylindric, peeled-dehiscent from the sides; seeds reddish brown; anthers 0.5–1.1 mm long, the sacs not septate.
      4a. Sepals (3.3–)4–7 mm long, ca. 3–4 times as long as wide; filaments (1.3–)1.5–3 mm long; style 1.25–2.5 mm long; bracteoles (1.5–)2.5 13 mm long; U.S. & Tabasco, Mexico ..... 1. *L. linifolia*
      4b. Sepals 1.8–3 mm long, 2 times as long as wide; filaments 0.75–1.1 mm long; style 0.55–0.9 mm long; bracteoles 0.7–2.5(–3) mm long; Cuba ..... 2. *L. stricta*
1b. Capsules various, less than twice as long as broad.
  5a. Flowers in compact racemes or spikes 1–5 cm long; stems single or with a few branches frequently overtopping the main stem; rhizomes often present ..... 6. *L. suffruticosa*

5b. Flowers axillary, in elongate, interrupted, leafy racemes or spikes 2–20 cm long; stems usually profusely branched; rhizomes absent.
6a. Plants densely pubescent throughout.
7a. Sepal apex elongate-acuminate or subcuspidate, reflexed; plants densely hirtellous; seed surface cells suborbicular ..... 10. *L. pilosa*
7b. Sepal apex acuminate, ascending; plants densely strigillose or hirtellous; seed surface cells columnar.
8a. Plants hirtellous; capsules oblong-obovoid; sepals greenish adaxially; bracteoles (1.5–)2–4.3 mm long, at or near capsule base ..... 11. *L. ravenii*
8b. Plants strigillose; capsules subglobose; sepals yellowish adaxially; bracteoles 0.5–1.5 mm long, usually on the short pedicel ..... 9. *L. sphaerocarpa*
6b. Plants subglabrous to glabrous.
9a. Capsules obpyramidal with narrowly winged corners.
10a. Stems nearly smooth or slightly ridged; sepals greenish, about ½ as long as the capsule; capsule wall flat between the wings; seed surface cells suborbicular; pollen grains shed as tetrads ..... 7. *L. lanceolata*
10b. Stems often distinctly ridged or winged; sepals creamy whitish, nearly as long as capsule; capsule wall between the wings bulging out longitudinally; seed surface cells elongate parallel to the seed length; pollen grains shed singly ..... 8. *L. alata*
9b. Capsules various, not winged.
11a. Nectary disc nearly flat on ovary apex; fruits 1–1.5 mm long, containing 10–20 seeds, often recognizable as bumps from outside; seeds reddish brown ..... 12. *L. microcarpa*
11b. Nectary disc distinctly raised on ovary apex; fruits 1.5–7 mm long, containing 40–500 seeds, not recognizable as bumps from outside; seeds light tan or yellowish.
12a. Cauline leaves lanceolate, oblong-elliptic to narrowly so; capsules dehiscing by irregular rupture of the outer walls; stolons present.
13a. Bracteoles 3.5–6.5(–8) mm long; sepals green, the apex elongate acuminate, reflexed; capsules oblong-obovoid with a constricted base ..... 5. *L. polycarpa*
13b. Bracteoles 0.5–1.5 mm long; sepals yellowish adaxially, the apex acuminate, ascending; capsules subglobose ..... 9. *L. sphaerocarpa*
12b. Cauline leaves obovate-spatulate, oblanceolate to very narrowly so; capsules dehiscing by 4 longitudinally lenticular slits on the wall opposite the loculi; stolons not common.
14a. Capsules 2.5–4.7 mm long; sepals 1.5–3 mm long; vestigial petals occasionally present; lower or seedling leaves always alternate ..... 14. *L. curtissii*
14b. Capsules 1.5–2.5 mm long; sepals 1.2–1.8 mm long; vestigial petals rare; lower or seedling leaves tending to be opposite or subopposite ..... 13. *L. simpsonii*

As in Figures 1–15 and 19–34, the sequence of the taxa in the taxonomic treatment reflects the possible phylogeny of *Ludwigia* sect. *Microcarpium*. Diploid petaliferous species that are presumably more primitively outcrossing are arranged first, followed by tetraploid members and the related hexaploid *L. alata*. *Ludwigia microcarpa*, an apetalous diploid, which definitely played a role in the formation of the distinct L. *curtissii* complex, is placed last along with the complex.

1. Ludwigia linifolia Poiret in Lam., Encycl. Suppl. 5: 513. 1817. *Isnardia linifolia* (Poiret) Kuntze, Rev. Gen. Pl. 1: 251. 1891. LECTOTYPE: "Amerique," *Poiret Herbarium* (P; lectotype here designated). Figure 35.

Plants glabrous. Stems erect or ascending, usually well branched, 12–55(–62) cm tall, aerenchyma rarely seen. Stolons slender, 4–15(–30) cm long, 0.7–1(–1.5) mm thick, seen in flowering season, the leaves narrowly obovate to narrowly oblanceolate, sometimes spatulate, 4.5–20 mm long, 1.3–6 mm wide, petioles 0.5–5 mm long. Cauline leaves linear or linear-oblanceolate, 15–40 mm long, (0.65–)0.9–4(–6) mm wide, the apex tapering into a sharp point or acute, margin entire with obscure hydathodal glands, the base very narrowly cuneate, sessile. Stipules narrowly ovate to narrowly lanceolate, 0.2–0.3 mm long, 0.1–0.2 mm wide. Flowers many, in leaf axils, their subtending leaves not reduced. Sepals green, narrowly triangular, ascending, (3.3–)4–7 mm long, 1.1–1.7 mm wide, glabrous or minutely papillose, the apex narrowly acute, the margin entire. Petals yellow, narrowly obovate-elliptic, 4–6 mm long, 2–4 mm wide, the apex obtuse or rounded, the base obtuse. Anthers 0.65–1.1 mm long; filaments yellowish, (1.3–)1.5–2.5(–3) mm long. Pollen shed as tetrads. Nectary disc bright yellow, elevated 0.3–0.7 mm on top of the ovary, 0.8–1.5 mm across, prominently 4-lobed, minutely papillose. Style yellow, 1.25–2.5 mm long, glabrous; stigma yellowish, 0.3–0.6 mm long, 0.6–0.8 mm thick, the apex

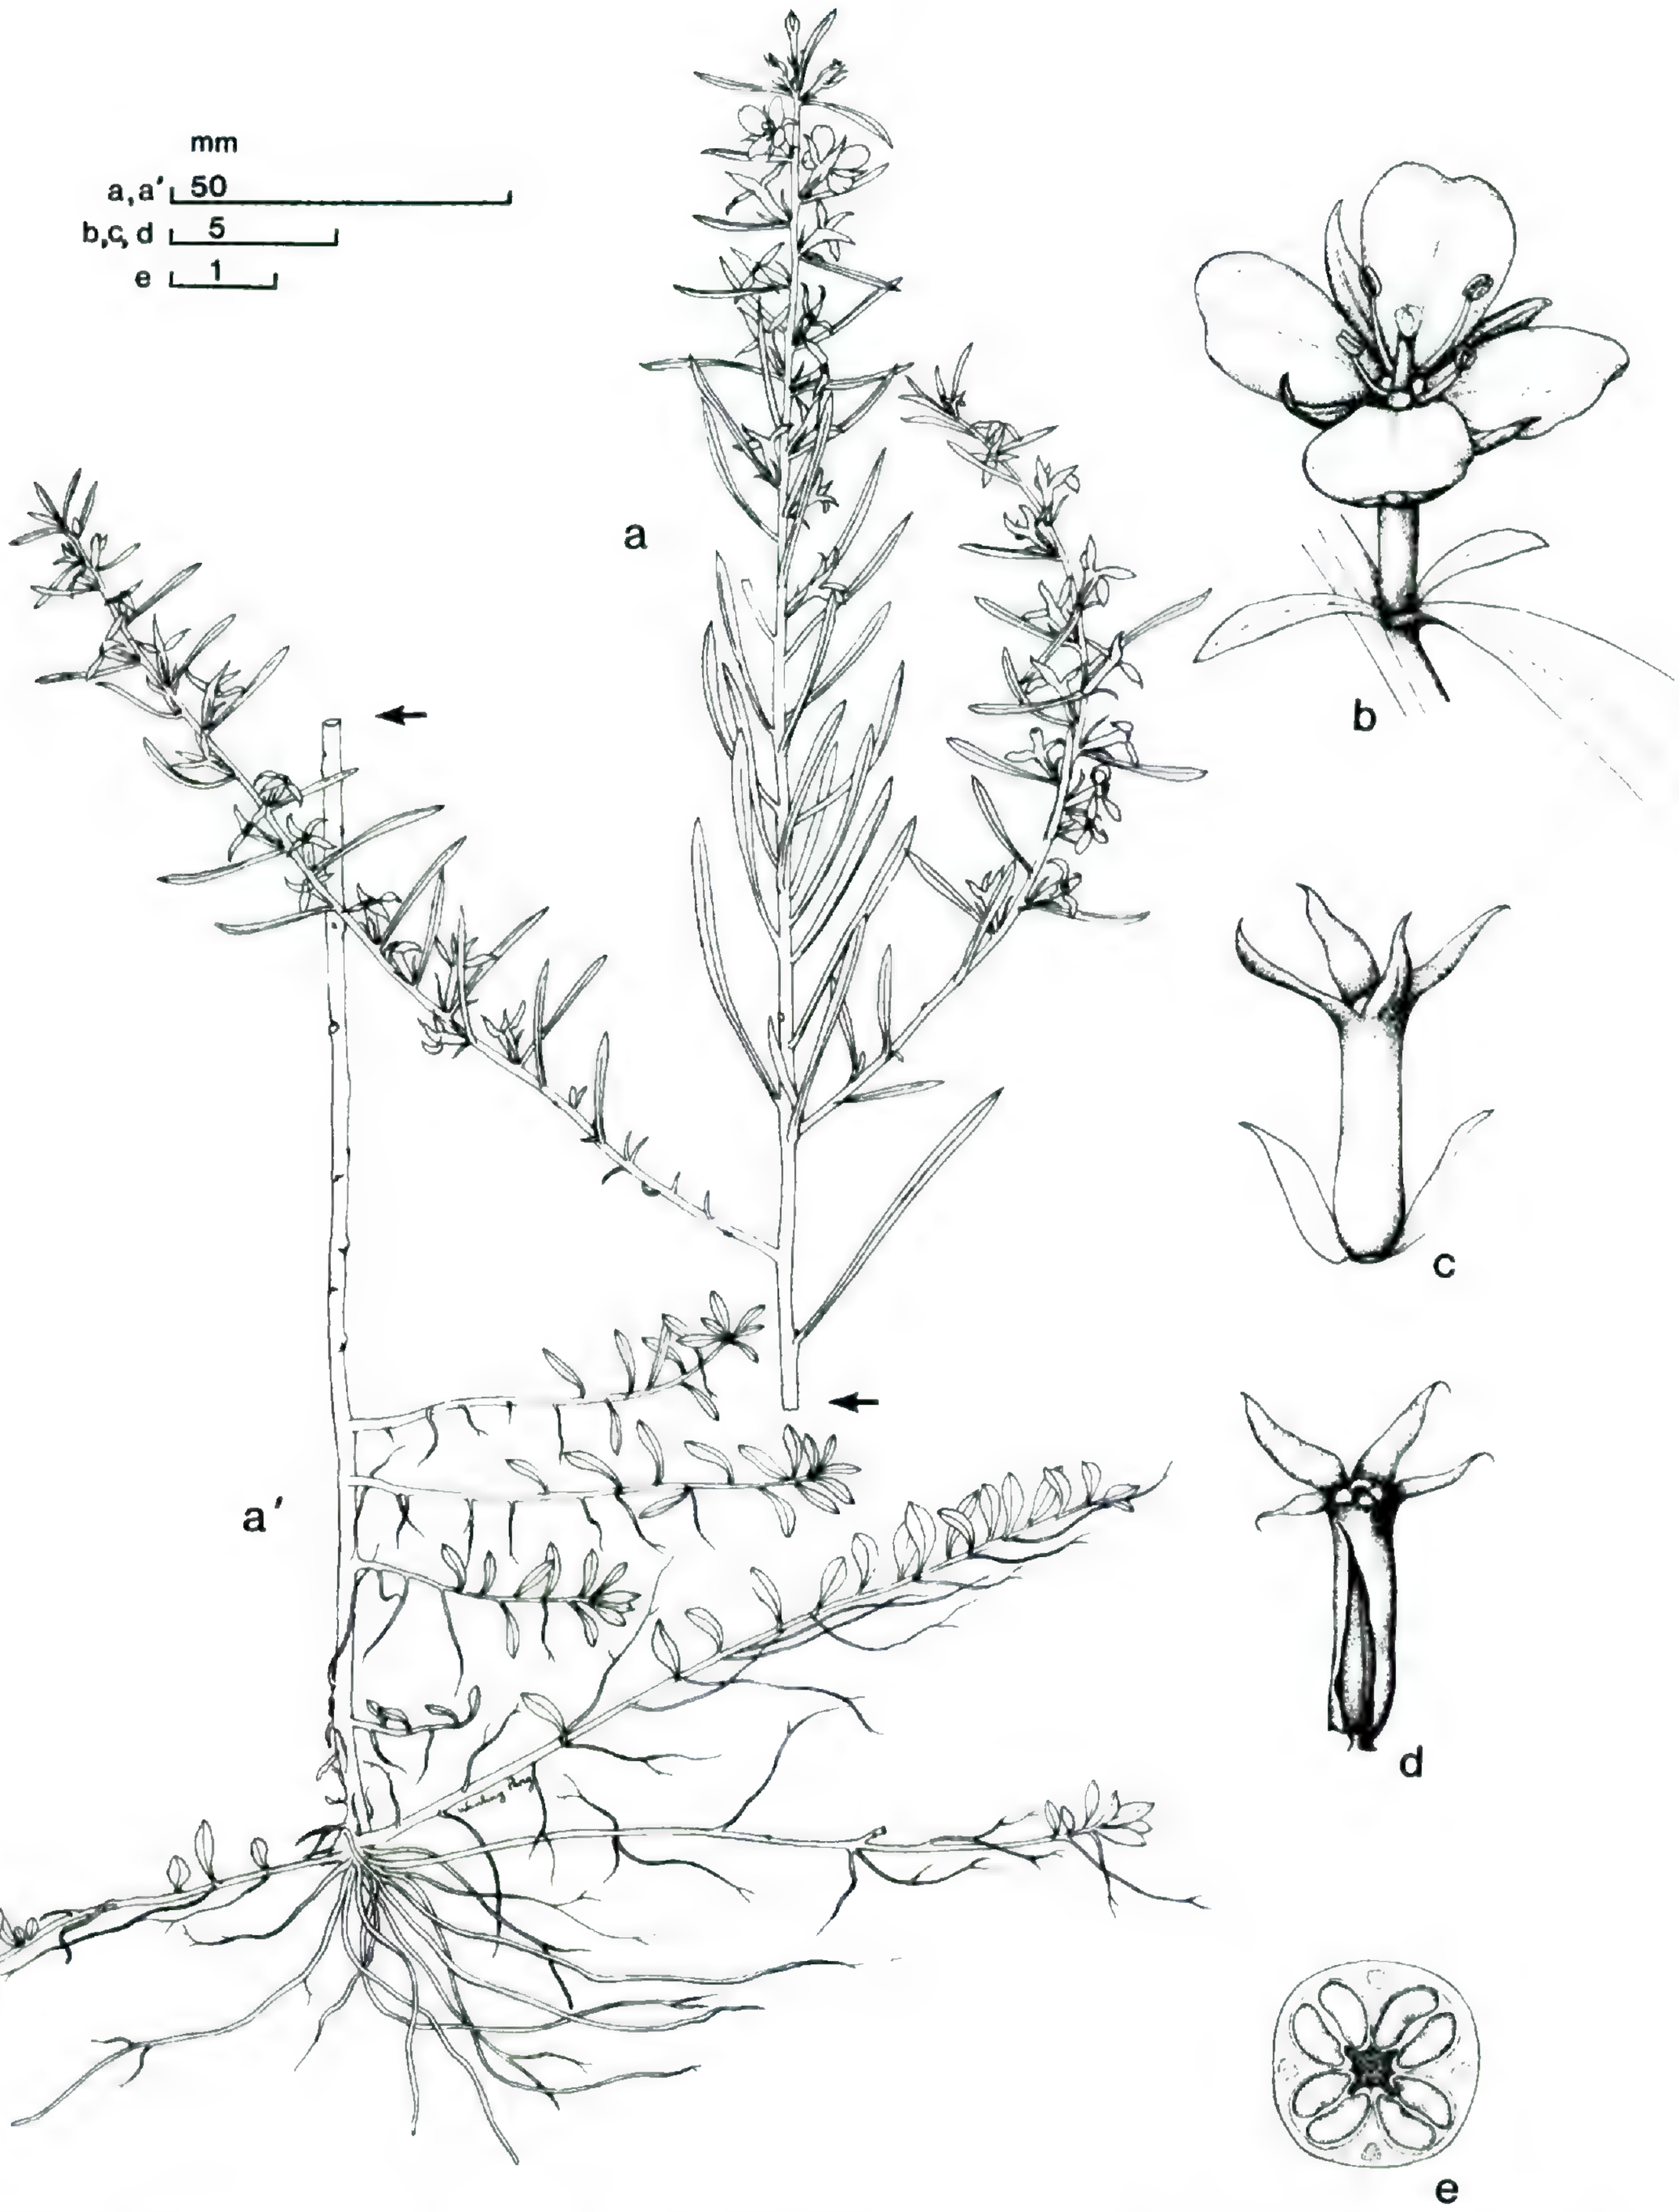

FIGURE 35. *Ludwigia linifolia*. Florida, Santa Rosa Co., *Godfrey 65936* (LL).—a. Habit, erect stem.—a′. Lower stem with basal stolons; stems continue at arrows.—b. Flower.—c. Mature capsule.—d. Dehiscent capsule.—e. Cross section of capsule.

shallowly 4-lobed. Capsules subcylindrical, slightly narrowed toward base, 5–10(–12) cm long, 1.3–2(–2.2) mm thick, densely minutely papillose, occasionally also remotely minutely scaberulous, the hairs 0.05–0.15 mm long, sessile. Bracteoles attached 0–1.5 mm above capsule base, very narrowly oblanceolate to linear, (1.5–)2.5–9(–13) mm long, 0.15–0.8 mm wide, the margin entire, ascending or spreading. Seeds reddish, oblong-elliptic with curved ends, 0.55–0.6 mm long, 0.2–0.3

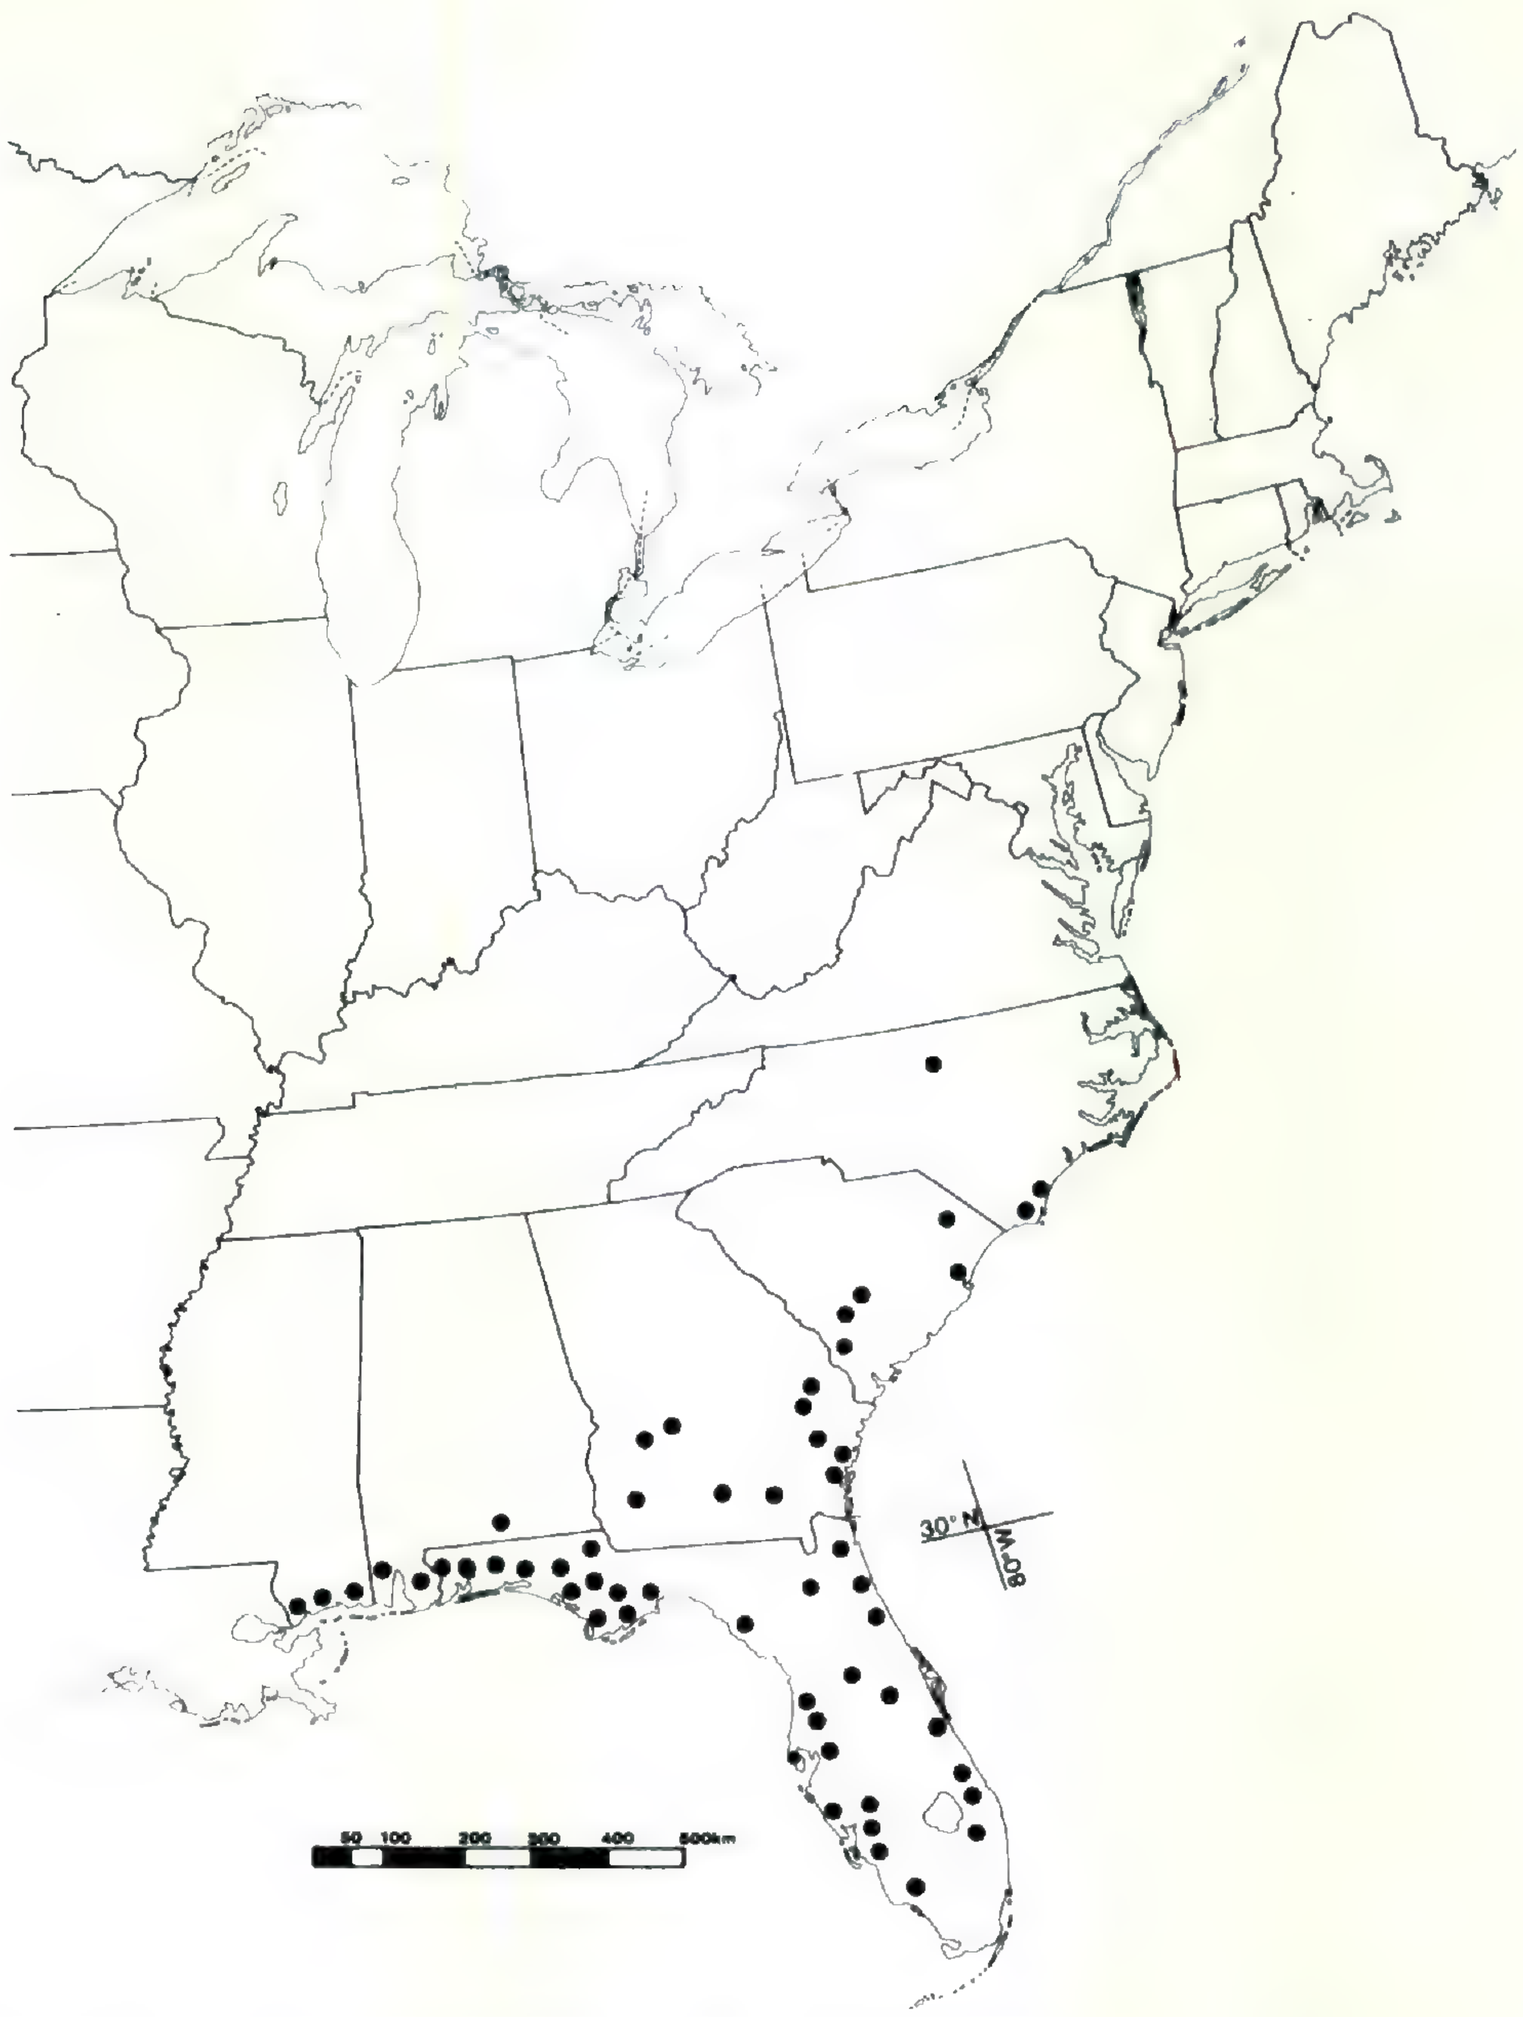

FIGURE 36. Distribution of *Ludwigia linifolia* in the United States.

mm thick, the surface cells nearly isodiametric. Self-compatible. Gametic chromosome number, $n = 8$.

Distribution. Plants of *L. linifolia* are often found in drainage ditches, along margins of creeks or swamps, on bottom meadow, on open edges of cypress swamps, in moist pineland, and along edges of brackish lakes. *Ludwigia linifolia* ranges along the Atlantic coast from extreme southeastern North Carolina and eastern South Carolina through southern Georgia and peninsular Florida. To the west, its range extends through the Florida panhandle, to extreme southern Alabama and Mississippi. A disjunct population has been collected in north-central North Carolina (Fig. 36). It is also known from a disjunct population at Huimanguillo, Tabasco, Mexico, on the Yucatán Peninsula. Flowering from late June through October; fruiting from July through November.

Representative specimens examined. U.S.A. ALABAMA: Baldwin Co., 3 mi. E of Southport, *Webster & Wilbur 3559* (FSU, GH, SMU, US). Covington Co., ca. 13.5 mi. Ludwigia linifolia is a relatively uniform species. Its variability chiefly affects the size of the capsules and the lengths of the bracteoles, which are attached to the sides of the capsule. Its closest affinity is definitely with *L. stricta*, a Cuban endemic, from which *L. linifolia* differs by having narrower leaves, larger floral parts (including sepals, anthers, filaments, and style), and longer fruits and bracteoles. Characters of the two species and the only other petaliferous member of the section, *L. linearis*, are listed for comparison in Table 3.

Ludwigia linifolia has somewhat showy petals and the most prominent nectary disc lobes occurring in sect. *Microcarpium*. The nectary disc is bright yellow and produces copious nectar at anthesis. Herbarium specimens often reveal empty anthers held away from the stigma (mechanical self-pollination has not occurred yet). This observation suggests that *L. linifolia* is probably modally outcrossing, which is corroborated by limited field observations.

Ludwigia linifolia occurs with *L. alata*, *L. curtissii*, *L. glandulosa*, *L. linearis*, *L. microcarpa*, and *L. pilosa* in the field. Natural hybrid populations have, however, been found only between *L. linifolia* ($n = 8$) and *L. curtissii* ($n = 32$). This is contrary to what one would expect for the outcrossing *L. linifolia*. However, experimental hybridizations (Peng, 1988) indicate that artificial hybrids between the diploid *L. linifolia* and plants of any other ploidy level in sect. *Microcarpium* are generally difficult to obtain. Repeated trials with different parental strains were successful in some cases, but the resulting hybrids were usually weak and needed special attention to reach flowering stage. Attempts to synthesize the natural hybrid *L. linifolia* × *L. curtissii* in the experimental greenhouse were unsuccessful.

2. Ludwigia stricta (Wright ex Griseb.) Wright in Wright & Sauvalle, Fl. Cubana 54. 1873. Based on *Isnardia stricta* Wright ex Griseb., Cat. Pl. Cub. 107. 1866. TYPE: eastern Cuba, 1860–1864, *C. Wright 2555* (holotype, GOET; isotypes, G, GH, MO, NY, P, US). Figure 37.

Plants glabrous throughout. Stems erect or ascending from stolons, simple or much branched, 10–60(–85) cm tall. Stolons 5–10 cm long, 1–2.5 mm thick, the leaves elliptic, 7.5–13 mm long, 3–5 mm wide, glabrous, the base attenuate into winged petioles up to 2 mm long. Cauline leaves deciduous from below in late growing season, oblanceolate to narrowly oblanceolate or narrowly elliptic, 11–22 mm long, 2.2–5.5 mm wide, glabrous, the apex acute, the margin with remote, minute hydathodal glands, the base narrowly cuneate into winged petiole 0–1.5 mm long. Stipules minute, ovate or lanceolate, succulent, dark brownish purple, 0.2–0.3 mm long, 0.1–0.2 mm wide. Flowers in upper leaf axils, their subtending leaves

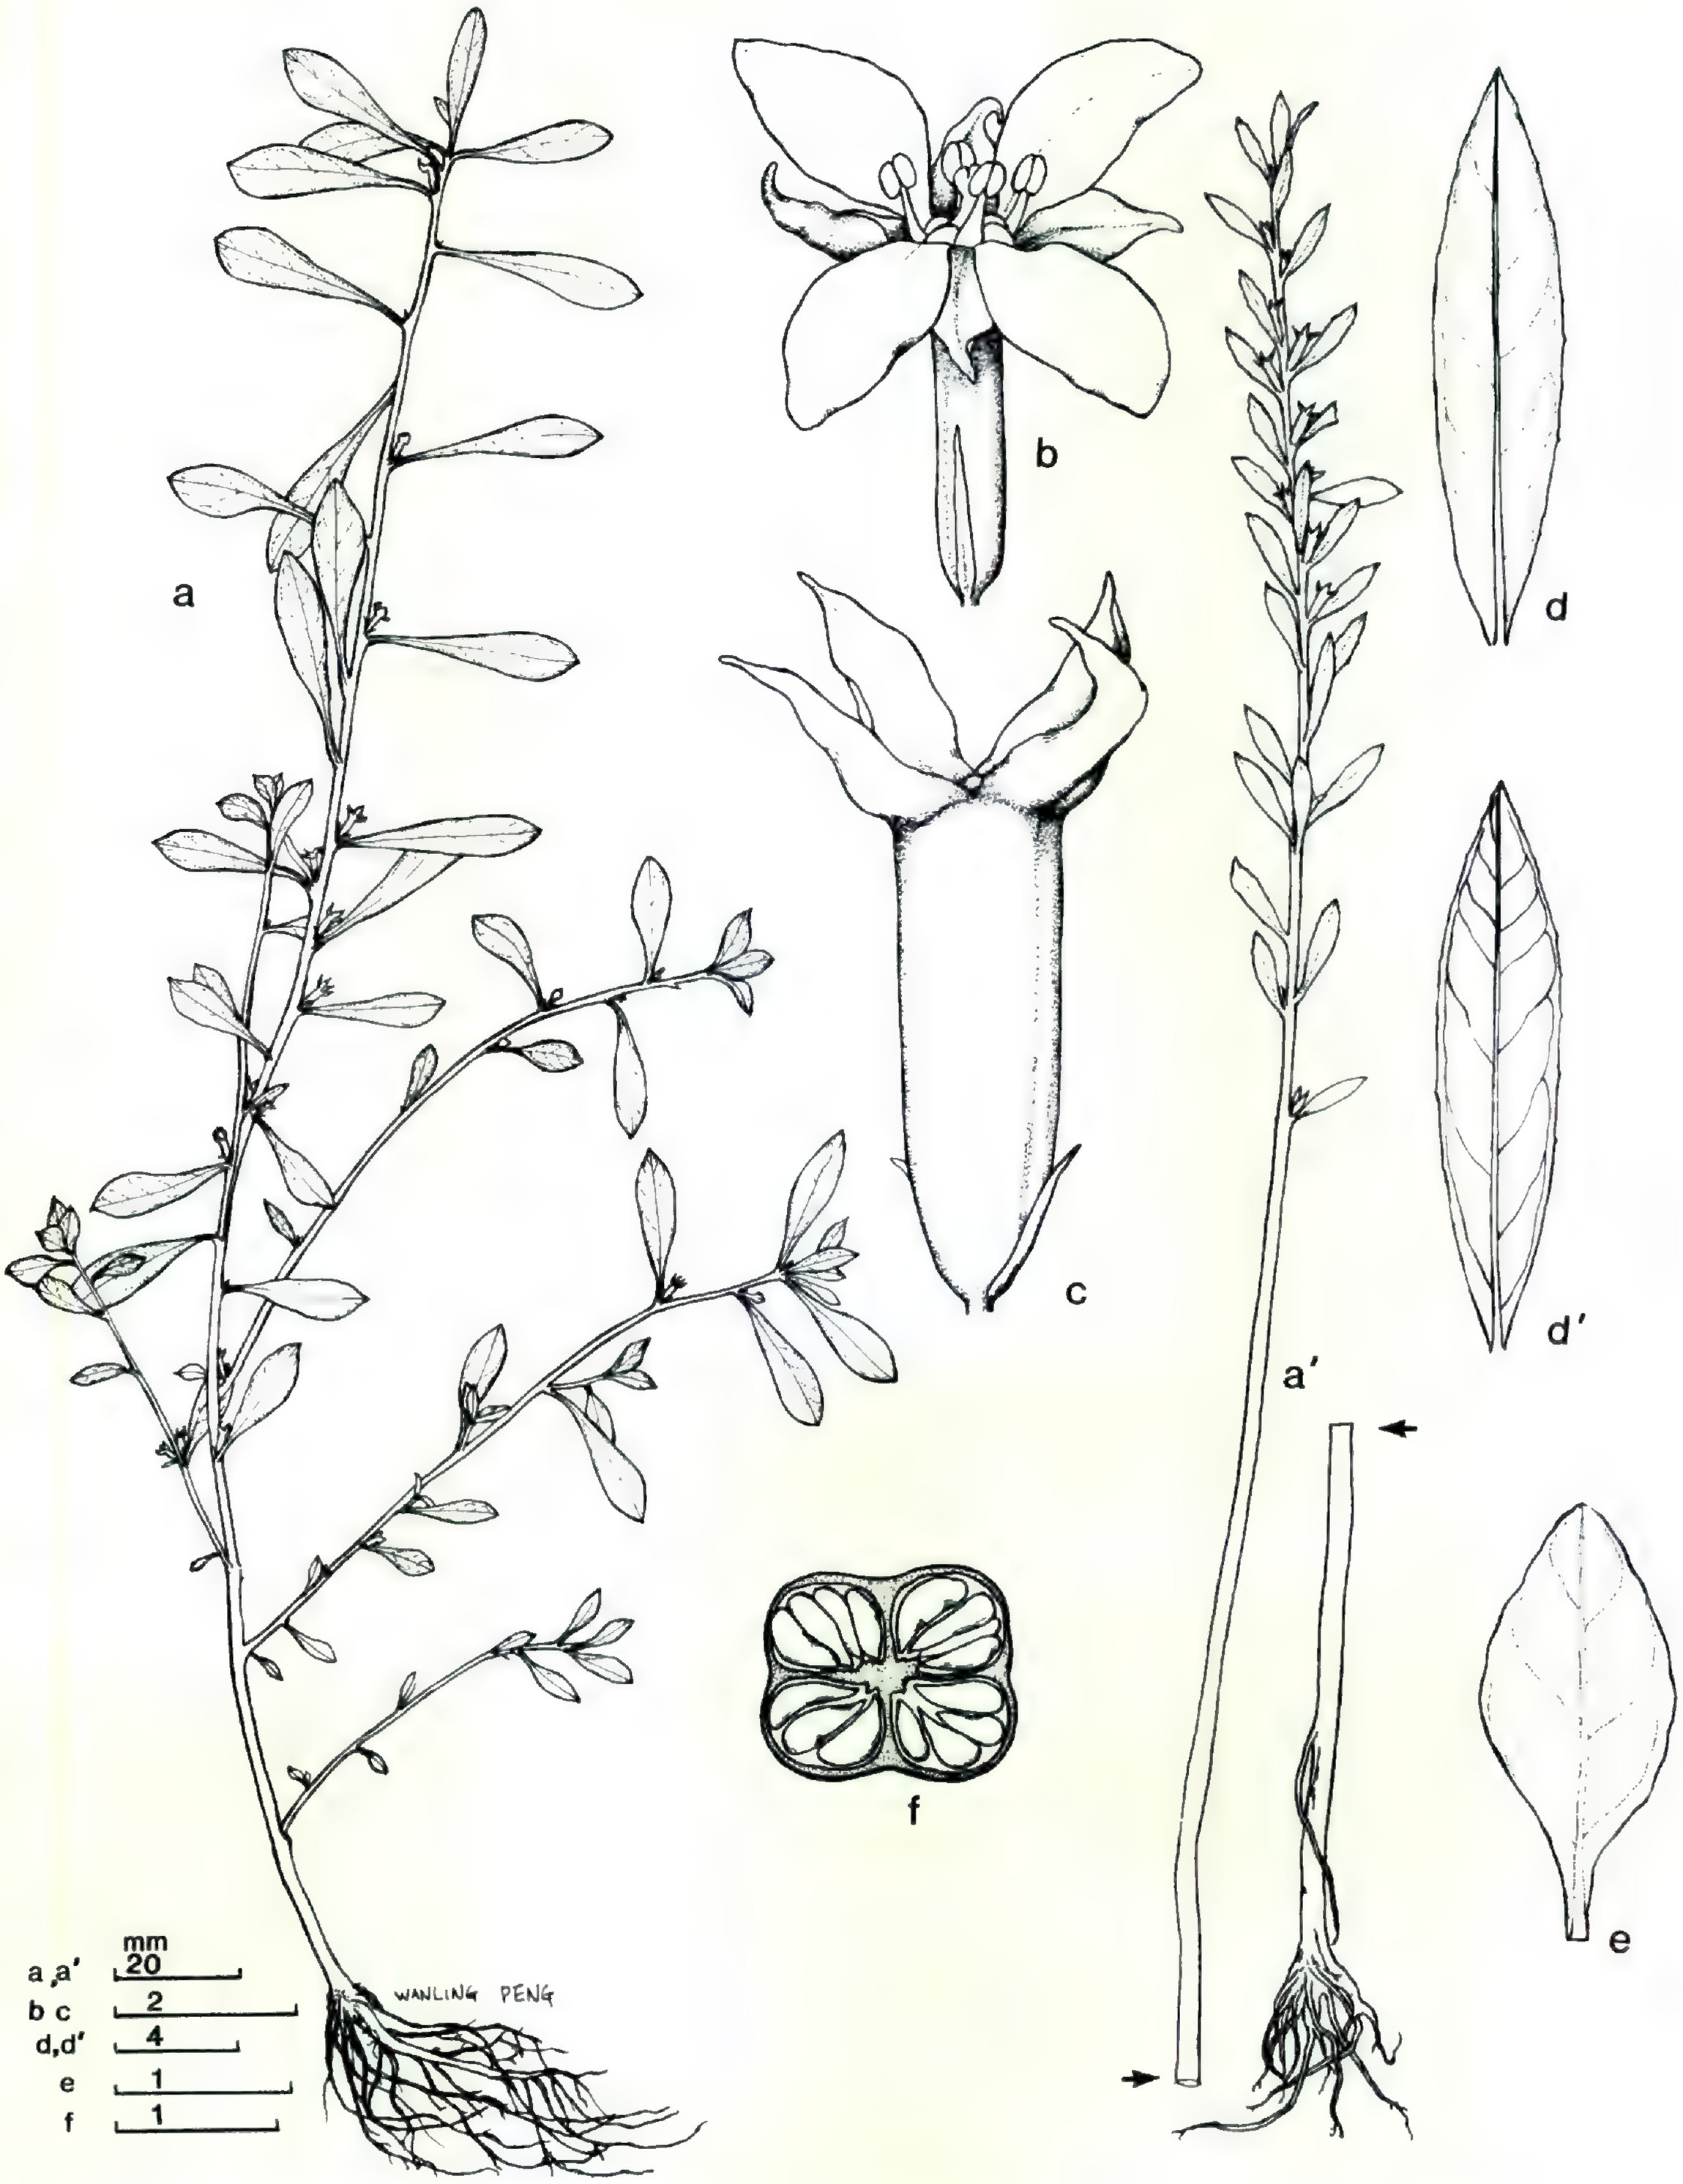

FIGURE 37. *Ludwigia stricta*. a′, c, d, d′, and f from Cuba (*Wright 2555*, US); a, b, and e from plants grown from seeds from Cuba (1982, *Leiva s.n.*, *M 3304*, MO).—a, a′. Habit, stem continues at arrows.—b. Flower.—c. Capsule.—d, d′. Adaxial and abaxial sides of leaf.—e. Petal.—f. Cross section of fruit.

not reduced. Sepals green, narrowly ovate-triangular, ascending, (1.8–)2–3 mm long, 0.9–1.5 mm wide, the apex narrowly acute or acuminate, the margin entire. Petals yellow, elliptic or narrowly obovate, 2.3–2.9 mm long, 1.2–1.3 mm wide, the apex obtuse, the base attenuate. Anthers 0.5–0.7 mm long; filaments 0.75–1.1 mm long. Pollen grains shed as tetrads. Nectary disc yellow, elevated 0.25–0.3 mm on top of the ovary, 1–1.25 mm across, 4-lobed, minutely papillose. Style 0.55–0.9 mm long, glabrous; stigma subglobose, 0.25–0.5 mm across. Capsules cylindrical, 5–6(–7) mm long, 1.6–1.8 mm thick, minutely papillose; pedicels 0–0.9 mm long. Bracteoles attached at capsule base, narrowly lanceolate, 0.7–2.5(–3) mm long, 0.2–0.4(–0.6) mm wide, the margin entire. Seeds reddish brown when mature, elliptic-oblong in outline, slightly curved on both ends, 0.5–0.6 mm long, 0.2–0.25 mm thick, the surface cells nearly isodiametric. Self-compatible. Gametic chromosome number, $n = 8$.

Distribution. *Ludwigia stricta* is a uniform species known only from Cuban lagoons and savannas (Fig. 38). Flowering and fruiting from August through November.

Representative specimens examined. CUBA. PIÑAR DEL RÍO: Herradura, *Britton et al. 6613* (NY); Piñar del Río, *Britton et al. 7233* (NY); 3 km S of Herradura, *Ekman 17742* (S). ISLA DE JUVENTUD (ISLA DE PINOS): between Los Indios and La Siguanea, *Ekman 12179* (S); Hotel Colony, *Rostánski 2028* (MO); 1982, *Leiva s.n.* (cultivated, MO).

Ludwigia stricta has a close affinity with *L. linifolia*, which is distributed in the southeastern United States and occurs on the Yucatán Peninsula in Tabasco, Mexico. Both are diploids; they are similar in stature, have four petals, shed their pollen as tight tetrads, have subcylindric capsules that dehisce irregularly from the sides, and have reddish brown seeds with subisodiametric surface cells. A comparison of these two species and the other petaliferous diploid species, *L. linearis*, is presented in Table 3.

Viable seeds of *L. stricta* have become available only recently. Plants have been grown and crossed with all three other diploid species of sect. *Microcarpium* in order to assess their genetic relationships.

3. Ludwigia linearis Walter, Fl. Carol. 89. 1788. *Isnardia linearis* (Walter) DC., Prodr. 3: 60. 1828. TYPE: U.S.A. "the Carolinas": *T. Walter 665* (holotype, BM, Walter Herbarium, p. 66; photograph, MO). Figure 39.

Ludwigia angustifolia Michaux, Fl. Bor.-Am. 1: 88. 1803. LECTOTYPE: U.S.A. South Carolina: near wet ditches, fl. Aug.-Sept., 1785–1796, *A. Michaux s.n.* (P; photographs, GH, MO; isolectotypes, MO, P—2 sheets; lectotype here designated, based on best collection of authentic material at P).

Ludwigia linearis Walter var. *puberula* Engelm. & A. Gray, Boston J. Nat. Hist. 5: 217. 1845. TYPE: U.S.A. Texas: Harris Co., Houston, July 1843, *F. J. Lindheimer 58* (holotype, GH; isotypes, BM, GOET, MO, P, PH, US).

Plants glabrous to densely minutely strigillose or sometimes puberulent, the hairs 0.05–0.15 mm long. Stems erect, often well branched, (22–)50–100(–145) cm tall, often with distinct aerenchyma in lower part. Stolons up to 30 cm long, 0.8–0.25 mm thick, seen in late fruiting season only, the leaves purplish, narrowly elliptic to very narrowly elliptic, 12–23 mm long, 2.8–8.5 mm wide, glabrous to sparingly minutely strigillose, the base attenuate into petioles up to 5 mm long. Cauline leaves green, linear to elliptic linear, 16–60(–85) mm long, 0.9–3.7(–5.6) mm wide, glabrous to densely minutely strigillose or puberulent, the apex very narrowly acute, the margin entire, the hydathodal glands obscure, the base very narrowly acute or cuneate, subsessile. Stipules narrowly ovate or lanceolate, 0.15–0.3 mm long, 0.05–0.15 mm wide. Flowers many, in leaf axils, their flower-subtending leaves not reduced. Sepals green, triangularly ovate to narrowly triangular, the apex acuminate or elongate acuminate to cuspidate, ascending, 2.3–5(–5.6) mm long, 1–3(–3.5) mm wide, glabrous, densely minutely scaly strigillose, strigillose, or puberulent without, glabrous within. Petals yellow, obovate to subrotund, 3–6 mm long, (2–)2.5–5 mm wide, the apex obtuse, the base attenuate. Anthers lanceolate oblong, 1–2 mm long, sporogenous tissue 4–8 packeted; filaments 1.1–2(–2.2) mm long. Packets in the sporogenous tissue opening and shedding tetrad pollen almost simultaneously. Nectary disc yellow, elevated (0.25–)0.35–0.55(–0.7) mm on top of the ovary, 1.3–2.5 mm across, 4-lobed, glabrous to minutely strigillose or strigillose, especially around lobe margins. Style yellowish green, (0.4–)0.7–1.5 mm long, glabrous throughout to densely strigillose, especially in the lower part. Stigma yellowish green, elongated, shallowly 4-lobed on apex, (0.6–)1–1.9 mm long. Capsules elongate obpyramidal, often with a shallow, central, longitudinal groove on each side, 5–10 (–12) mm long, 2–5.5 mm thick, glabrous, densely scaly strigillose, strigillose, or puberulent, subsessile or with distinct pedicels up to 3.5(–5) mm long. Bracteoles subequal, attached near capsule base to 4.5 mm above base or on the pedicel, linear, 0.4–

FIGURE 38. Distributions of *Ludwigia alata* (circles) and *L. stricta* (triangles).

4(–7.5) mm long, 0.1–0.3 mm wide, deciduous. Seeds light brown, oblong-elliptic with slightly curved ends, 0.45–0.65 mm long, 0.15–0.25 mm wide, the surface cells oblong, elongate either parallel or transversely to the seed length. Self-compatible. Gametic chromosome number, $n = 8$.

Distribution. *Ludwigia linearis* is common in drainage ditches, along river or stream banks, swales, edges of pocosins, sandy soil in wet meadows, brackish marshes, and occasionally on disturbed ground. It is distributed along the Atlantic coast from southern New Jersey through Delaware, the eastern halves of North and South Carolina, southern Georgia, to its southern limit in central Florida. Westwards, this species extends through the panhandle of Florida and across Alabama, southern Mississippi, and Louisiana, to the central Gulf coast of Texas. To the north, *L. linearis* ranges through eastern Texas and across southern Arkansas, and there is a northward range extension from northern Alabama into Tennessee (Fig. 40).

W of Stony Creek, *Howell 20491* (1, NCU). Warwick Co., near Newport News, 1907, *Long & Long s.n.* (1, US).

The variation pattern of *Ludwigia linearis* is highly complicated as a result of a great deal of intergradation among slightly differentiated geographical races. I have classified the varied populations into four categories: 1) the subglabrous morph, 2) the densely strigillose morph, 3) the completely glabrous morph, and 4) the intermediate morph, which is discussed below.

1. *Subglabrous morph.* Stems sparingly minutely strigillose. Cauline leaves glabrous except for the minutely strigillose margin. Sepals 2.3–4 (–4.5) mm long, 1.3–2.4(–3) mm wide, the apex acuminate, minutely scaly strigillose abaxially. Anthers 1.1–1.6 mm long, the filaments 1.3–1.8 (–2.1) mm long. Nectary disc minutely scaly strigillose around margins of the lobes. Style (0.4–)0.7–0.9(–1.2) mm long, glabrous. Stigma (0.6–)1–1.5 mm long. Capsules densely minutely scaly strigillose, 5–8.5(–10) mm long, 2–4(–5) mm thick, sessile or with a constricted, pedicel-like base. Bracteoles 0.4–1.6(–2.5) mm long. Seed surface cells columnar, elongate parallel to the seed length.

The type of *Ludwigia linearis* Walter belongs to this morph. Plants of this sort are distributed along the Atlantic coast from southern New Jersey through Delaware, eastern Maryland, eastern Virginia, eastern halves of North Carolina and South Carolina, and Georgia, to their southern limit in the central Florida peninsula. They extend westward through the panhandle of Florida and across Alabama and southern Mississippi, reaching eastern Louisiana (Washington and St. Tammany parishes only). Northward, they occur throughout the eastern half of Alabama and extend to central Tennessee.

2. *Densely strigillose morph.* Stems and leaves densely minutely strigillose to puberulent in some cases. Sepals 3–5 mm long, 1.5–2.5(–3.5) mm wide, the apex cuspidate or elongate-acuminate, minutely strigillose or puberulent abaxially. Anthers (1.1–)1.3–2 mm long, the filaments (1.2–)1.5–2(–2.2) mm long. Nectary disc minutely scaly strigillose throughout or only surrounding margins of the lobes. Style (0.6–)0.9–1.5 mm long, glabrous to densely strigillose, especially on the lower part. Stigma (1–)1.3–1.9 mm long. Capsules densely minutely strigillose or puberulent, 5–10 (–12) mm long, 3–5.5 mm thick, the base sessile

or with distinct pedicels up to 5 mm long. Bracteoles 0.5–4(–7.5) mm long. Seed surface cells columnar, elongate transversely to the seed length.

Plants of this morph were recognized at varietal rank, *Ludwigia linearis* var. *puberula*, by Engelmann & Gray (1845). They occur most frequently in central and southern Arkansas, western Louisiana, and the eastern half of Texas. Scattered populations, however, occur east of the Mississippi River in eastern Louisiana and southern Mississippi. A single population was found in Dallas County in southcentral Alabama.

In addition to being much more pubescent than plants of the subglabrous morph, plants of the densely strigillose morph are slightly larger in the size of most floral parts. Furthermore, their seed surface cell pattern is different from that of the subglabrous morph. The cells are elongate parallel to the seed length in the subglabrous morph but are elongate transversely to the seed length in the densely strigillose morph.

3. *Completely glabrous morph.* Characters of this morph are exactly the same as those of the densely strigillose morph, except that the former is glabrous throughout. Indeed, many plants of the completely glabrous morph were collected along with those of the densely strigillose morph. Examples are as follows:

U.S.A. ARKANSAS: Prairie Co., low moist areas in rice paddies, P. O. Hazen, *Demaree 37904* (completely glabrous morph: TEX, VDB-22422, VDB-47595; mixed collection of both the completely glabrous morph and the densely strigillose morph: VDB-33725). Lonoke Co., moist low ground, prairie in rice belt, P. O. Carlisle, *Demaree 22327* (mixed collection of completely glabrous morph and the densely strigillose morph: CAS). LOUISIANA: Bossier Parish, 10 mi. S of Plain Dealing, fire lane in young pine–hardwood stand, sandy loam, *Shinners 24488* (completely glabrous morph: NO; densely strigillose morph: SMU). TEXAS: Waller Co., ditches, Hempstead, *Hall 221* (completely glabrous morph: GH, MO; densely strigillose morph: NY; mixed collection: F, NY—2 sheets, US).

In these cases floral and vegetative characters and even the seed surface pattern are exactly the same in the completely glabrous and the densely strigillose individuals. Plants of these two morphs may well differ only by a single allele that controls the expression of pubescence in plants. It is also worth noting that plants of the completely glabrous morph are only found scattered in Arkansas, Louisiana, and Texas, the main distribution range of the densely strigillose populations. Plants of the completely glabrous morph were previously included by Munz (1944, 1965) as a part of the population of the subglabrous morph (as *Ludwigia linearis* var. *linearis*), which is certainly not appropriate, as discussed above.

Similarly, completely glabrous individuals that are apparently single-allele mutants in populations consisting mainly of densely pubescent plants but are otherwise similar morphologically occur in *Ludwigia hirtella* Raf. (sect. *Ludwigia*; Peng, unpublished).

4. *Intermediate morph.* Any plant that is more pubescent than those of the subglabrous morph and less pubescent than the densely strigillose morph is considered "intermediate" here. The pubescence ranges from scattered minutely strigillose on abaxial midvein and/or submarginal veins to sparingly strigillose on both surfaces of the leaves. The capsule wall is minutely strigillose and not scaly strigillose. Floral characters generally fall in the intermediate range of the subglabrous and the densely strigillose morphs. The seed surface cells, mostly elongate transversely to the seed length, are similar to those of the densely strigillose morph. In some cases, however, the seed surface does not have well-defined cells and is difficult to study. At other times, it is clearly intermediate between that of the subglabrous and the densely strigillose morphs.

Plants of the intermediate morph are widely scattered throughout the range of both the subglabrous morph and the densely strigillose/completely glabrous morphs. They are found in two counties in coastal North Carolina, very well represented in the Coastal Plain of South Carolina, scattered in a few counties in Georgia, Florida, and Alabama, and abundant in Mississippi, where the subglabrous and densely strigillose morphs meet. West of the Mississippi River, they are also found as scattered populations in Arkansas, Louisiana, and Texas, the main distribution range of the densely strigillose morph.

Plants designated as "intermediate morph" here represent an artificial assemblage of plants of *Ludwigia linearis* that may have originated from various combinations of somewhat differentiated populations. For example, the intermediate plants east of the Mississippi River often co-occur with subglabrous plants and may represent hybrids and their derivatives between plants of the subglabrous and of the densely strigillose morphs. On the other hand, intermediate plants that grow west of the Mississippi River may represent hybrids and their derivatives between the completely glabrous morph and the densely strigillose morph, as suggested by the following mixed collections:

U.S.A. ARKANSAS: Prairie Co., along 70, E of Carlisle, *Buker in 1956* (mixed collection of one glabrous plant

TABLE 4. Comparison of subglabrous and densely strigillose populations in *Ludwigia linearis*.

Characters	Subglabrous Populations	Densely Strigillose Populations
Leaves	Completely glabrous on both sides but with minutely strigillose margins	Densely minutely strigillose or puberulent on both surfaces
Bracteole length (mm)	0.4–1.6(–2.5)	0.5–4(–7.5)
Sepal		
Apex	Acuminate	Elongate-acuminate or cuspidate
Length (mm)	2.3–4	3–5(–5.6)
Vestiture	Densely minutely scaly-papillose, the hairs 0.02–0.05 mm long, appressed	Densely minutely strigillose, the hairs 0.06–1 mm long, appressed to ascending
Stigma length (mm)	(0.6–)1–1.5	(1–)1.3–1.9
Style	Glabrous	Glabrous to densely minutely strigillose
Seed surface cells	Elongate parallel to the seed length	Elongate transversely to the seed length
Pedicel length (mm)	0–0.4	0–3.5(–5)

and two intermediate plants). LOUISIANA: Winn Parish, infrequent in open area in dry pine forest ca. 3 mi. NW of Atlanta, in sec. 21 T10N R4W, *Allen 7172* (completely glabrous morph: USF; intermediate morph: NCU).

Plants of the subglabrous populations are somewhat distinguishable from the densely strigillose plants (Table 4) and are separable geographically (the boundary is roughly along the Mississippi River). Engelmann & Gray (1845) formally recognized the distinctiveness of the two morphs. However, with the abundant intergradation between the two races of *L. linearis*, as already noted by Engelmann & Gray (1845), ". . . these characters (of *L. linearis* var. *puberula*) gradually shading away into the ordinary *L. linearis*, . . . ," as well as the occurrence of the completely glabrous populations that have further complicated the character combinations of *L. linearis*, I think a discussion of the variation pattern within this species is more useful than recognizing infraspecific taxa.

Ludwigia linearis was reported as naturalized in marshy areas of Japan (Asai, 1970), and this report was taken up by Osada (1976) in his illustrations of the naturalized plants of Japan. However, an examination of Asai's voucher specimen at TI (Japan: Honshu, Mie Pref., Suzuka-shi, Asahigaoka-machi (Shirako-machi), October 9, 1966, *H. Ohta s.n.*) revealed that it actually represents *L. perennis* L. (sect. *Caryophylloidea*), which is widely distributed in the tropics and subtropics of the Old World and ranges north to Taiwan and southeastern China (Raven, 1963).

Ludwigia linearis can readily be recognized by its sublinear leaves, four yellow petals, and elongate-obpyramidal capsules with a shallow, central, longitudinal groove on each side. The only other species in sect. *Microcarpium* with which *L. linearis* might be confused is *L. linifolia*, which also occurs in the Coastal Plain and the Florida peninsula, but much less commonly. These two species are similar in having very narrow leaves, petaliferous flowers, and elongate capsules. My biosystematic study (Peng, 1988) has shown that they differ by at least a reciprocal translocation. A comparison of morphological characteristics in these two related species and *L. stricta*, which is endemic to Cuba, is petaliferous, and has elongate capsules, is summarized in Table 3.

Ludwigia linearis and the unrelated Latin American congener *L. latifolia* are unique in the genus in having conspicuous, transverse parenchymatous septa in the anthers, which divide the sporogenous tissue into packets (Eyde, 1977; Tobe & Raven, 1986). Before the dehiscence of the anther, however, all of these packets fuse and form one continuous area of sporogenous tissue as a result of disintegration of the septa, leaving the conspicuous vestiges of the distintegrated septa on the inner surface of the anther wall (Tobe & Raven, 1986).

Ludwigia linearis is facultatively outcrossing, having four stamens held away from the stigma at early anthesis and arched over, tightly appressed against the unique, elongate stigma a few hours after anthesis.

Ludwigia linearis is usually very floriferous and has the highest seed set per capsule in sect. *Microcarpium*, about 600 seeds per mature capsule.

Ludwigia linearis co-occurs with *L. glandulosa*, *L. lanceolata*, *L. linifolia*, *L. microcarpa*, *L. pilosa*, *L. sphaerocarpa*, and *L. suffruticosa* in the field. Confirmed natural hybrids include *L. linearis* × *L. glandulosa* (two collections) and *L. linearis* × *L. sphaerocarpa* (one collection). In both cases, hybrids are triploid, fertility as to seed and pollen is nearly zero. Ovaries turn yellowish

or pink after anthesis and then abort. One to four petals are often present in most flowers.

4. Ludwigia glandulosa Walter, Fl. Carol. 88. 1788. TYPE: U.S.A. "the Carolinas": s.d., *T. Walter 612* (holotype, BM, Walter Herbarium, p. 66; photograph, MO).

Plants subglabrous. Stems erect, usually well branched, 10–80(–100) cm tall, glabrous to sparingly minutely strigillose on the ridges formed by the decurrent leaf bases, the hairs ca. 0.05–0.1 mm long. Stolons up to 20 cm long, the leaves purplish, narrowly elliptic, 15–35(–55) mm long, 5–12.5(–20) mm wide, attenuate into petioles 3–10 mm long. Cauline leaves narrowly elliptic to sublinear, sometimes elliptic, those on the main stem 30–120 mm long, 3–25 mm wide, those on the branches usually reduced, 8–45 mm long, 2–10 mm wide; leaves glabrous to sparingly minutely strigillose on abaxial veins, the hairs ca. 0.025–0.05 mm long, apex acute to very narrowly acute, margin entire in outline, densely fringed with microscopic, papillose-strigillose hairs, hydathodal glands often visible, base attenuate, sessile or with petioles up to 15 mm long. Stipules reddish purple, ovate-triangular, succulent, ca. 0.15–0.35 mm long, 0.05–0.25 mm wide. Flowers often numerous, congested in leaf axils. Sepals ovate-deltoid, ascending, 1.1–2.3 mm long, 1–1.75 mm wide, glabrous, apex short acuminate or acute, margin entire, fringed with minute strigillose hairs. Petals 0. Anthers 0.3–0.5 mm long; filaments nearly translucent, 0.55–1 mm long. Pollen grains shed as tetrads. Nectary disc greenish, raised ca. 0.25–0.4 mm on top of ovary, 0.6–1.8 mm across, 4-lobed, glabrous. Style pale green, 0.3–0.75 mm long, glabrous. Stigma greenish, subglobose, 0.25–0.5 mm across. Capsules subcylindrical with 4 shallow grooves, each below the midvein of the sepal, 2–7(–9) mm long, 1.3–2(–3) mm thick, glabrous to minutely papillose-strigillose, the hairs 0.02–0.05 mm long, sessile or with pedicels up to 0.35 (–0.5) mm long, well spaced on main stems and primary branches, often congested on short secondary or tertiary branches. Bracteoles flanking capsule base or attached up to 2.1 mm above capsule base, rarely on the short pedicel, lance-linear or linear, 0.35–1 mm long, 0.1–0.35 mm wide. Seeds light brown, kidney-shaped, the ends slightly pointed, ca. 0.5–0.75 mm long, 0.25–0.4 mm thick, surface cells columnar, elongate either parallel or transversely to the seed length. Self-compatible. Gametic chromosome number, $n = 16$.

KEY TO THE SUBSPECIES OF *LUDWIGIA GLANDULOSA*

Capsules (4–)5–8(–9) mm long; seed surface cells elongate parallel to seed length ..... a. subsp. *glandulosa*

Capsules 2–4 mm long; seed surface cells elongate transversely to seed length ..... b. subsp. *brachycarpa*

The two entities here regarded as subspecies of *Ludwigia glandulosa* were first recognized as distinct by Torrey & Gray (1838–1840). *Ludwigia glandulosa* subsp. *brachycarpa* differs from subsp. *glandulosa* in its smaller stature, narrower leaves, and smaller flowers and capsules. Furthermore, the seed surface pattern of these two entities—a feature that is often diagnostic in *Ludwigia* sect. *Microcarpium*—is sharply distinct, as given in the key.

Ludwigia glandulosa subsp. *glandulosa* is very common and widespread throughout the Atlantic and Gulf coastal plains and the Mississippi Embayment, westward to eastern Texas and southeastern Oklahoma. Subspecies *brachycarpa* ranges just on the western edge of that of the subsp. *glandulosa* in northern Texas and Oklahoma. It grows in the same area as subsp. *glandulosa* throughout much of its range but extends farther south and west. The general distinctiveness of these two subspecies, without doubt, is maintained by their modal autogamy; vegetative reproduction by means of stolons may likewise play a role in preserving favored genotypes.

4a. Ludwigia glandulosa Walter subsp. **glandulosa.** Figure 41.

Jussiaea brachycarpa Lam., Encycl. 3: 331. 1789. TYPE: U.S.A. South Carolina: s.d., *J. Fraser s.n.* (holotype, P, photograph, MO).

Ludwigia heterophylla Poiret in Lam., Encycl. Suppl. 3: 512. 1814. TYPE: U.S.A. "the Carolinas": 1798–1800, *L. A. G. Bosc s.n.* (holotype, P).

Ludwigia cylindrica Elliott, Sketch Bot. S.C. & Ga. 1: 213. 1817. TYPE: U.S.A. South Carolina: Beaufort Co., Burton's Hill, near Beaufort, Aug.–Sept., s.d., *W. Baldwin s.n.* (holotype, CHARL; isotypes, GH, MO, NY; possible isotype, PH).

Stems often reddish, (20–)40–80(–100) cm tall. Cauline leaves elliptic to very narrowly elliptic, those on main stem 32–120 mm long, 4–21 mm wide, those on the branches much smaller, 10–45 mm long, 3–10 mm wide, petioles 1–15 mm long. Sepals ovate-deltoid, the apex acuminate, 1.25–2.3 mm long, 1.15–1.7 mm wide. Petals 0. Anthers 0.3–0.5 mm long; filaments 0.55–1 mm long. Pollen grains shed as tetrads. Nectary disc glabrous. Style 0.3–0.5 mm long; stigma 0.35–0.5 mm across. Capsules (4–)5–8(–9) mm long, 1.6–2(–3) mm thick, sessile or with pedicels up to

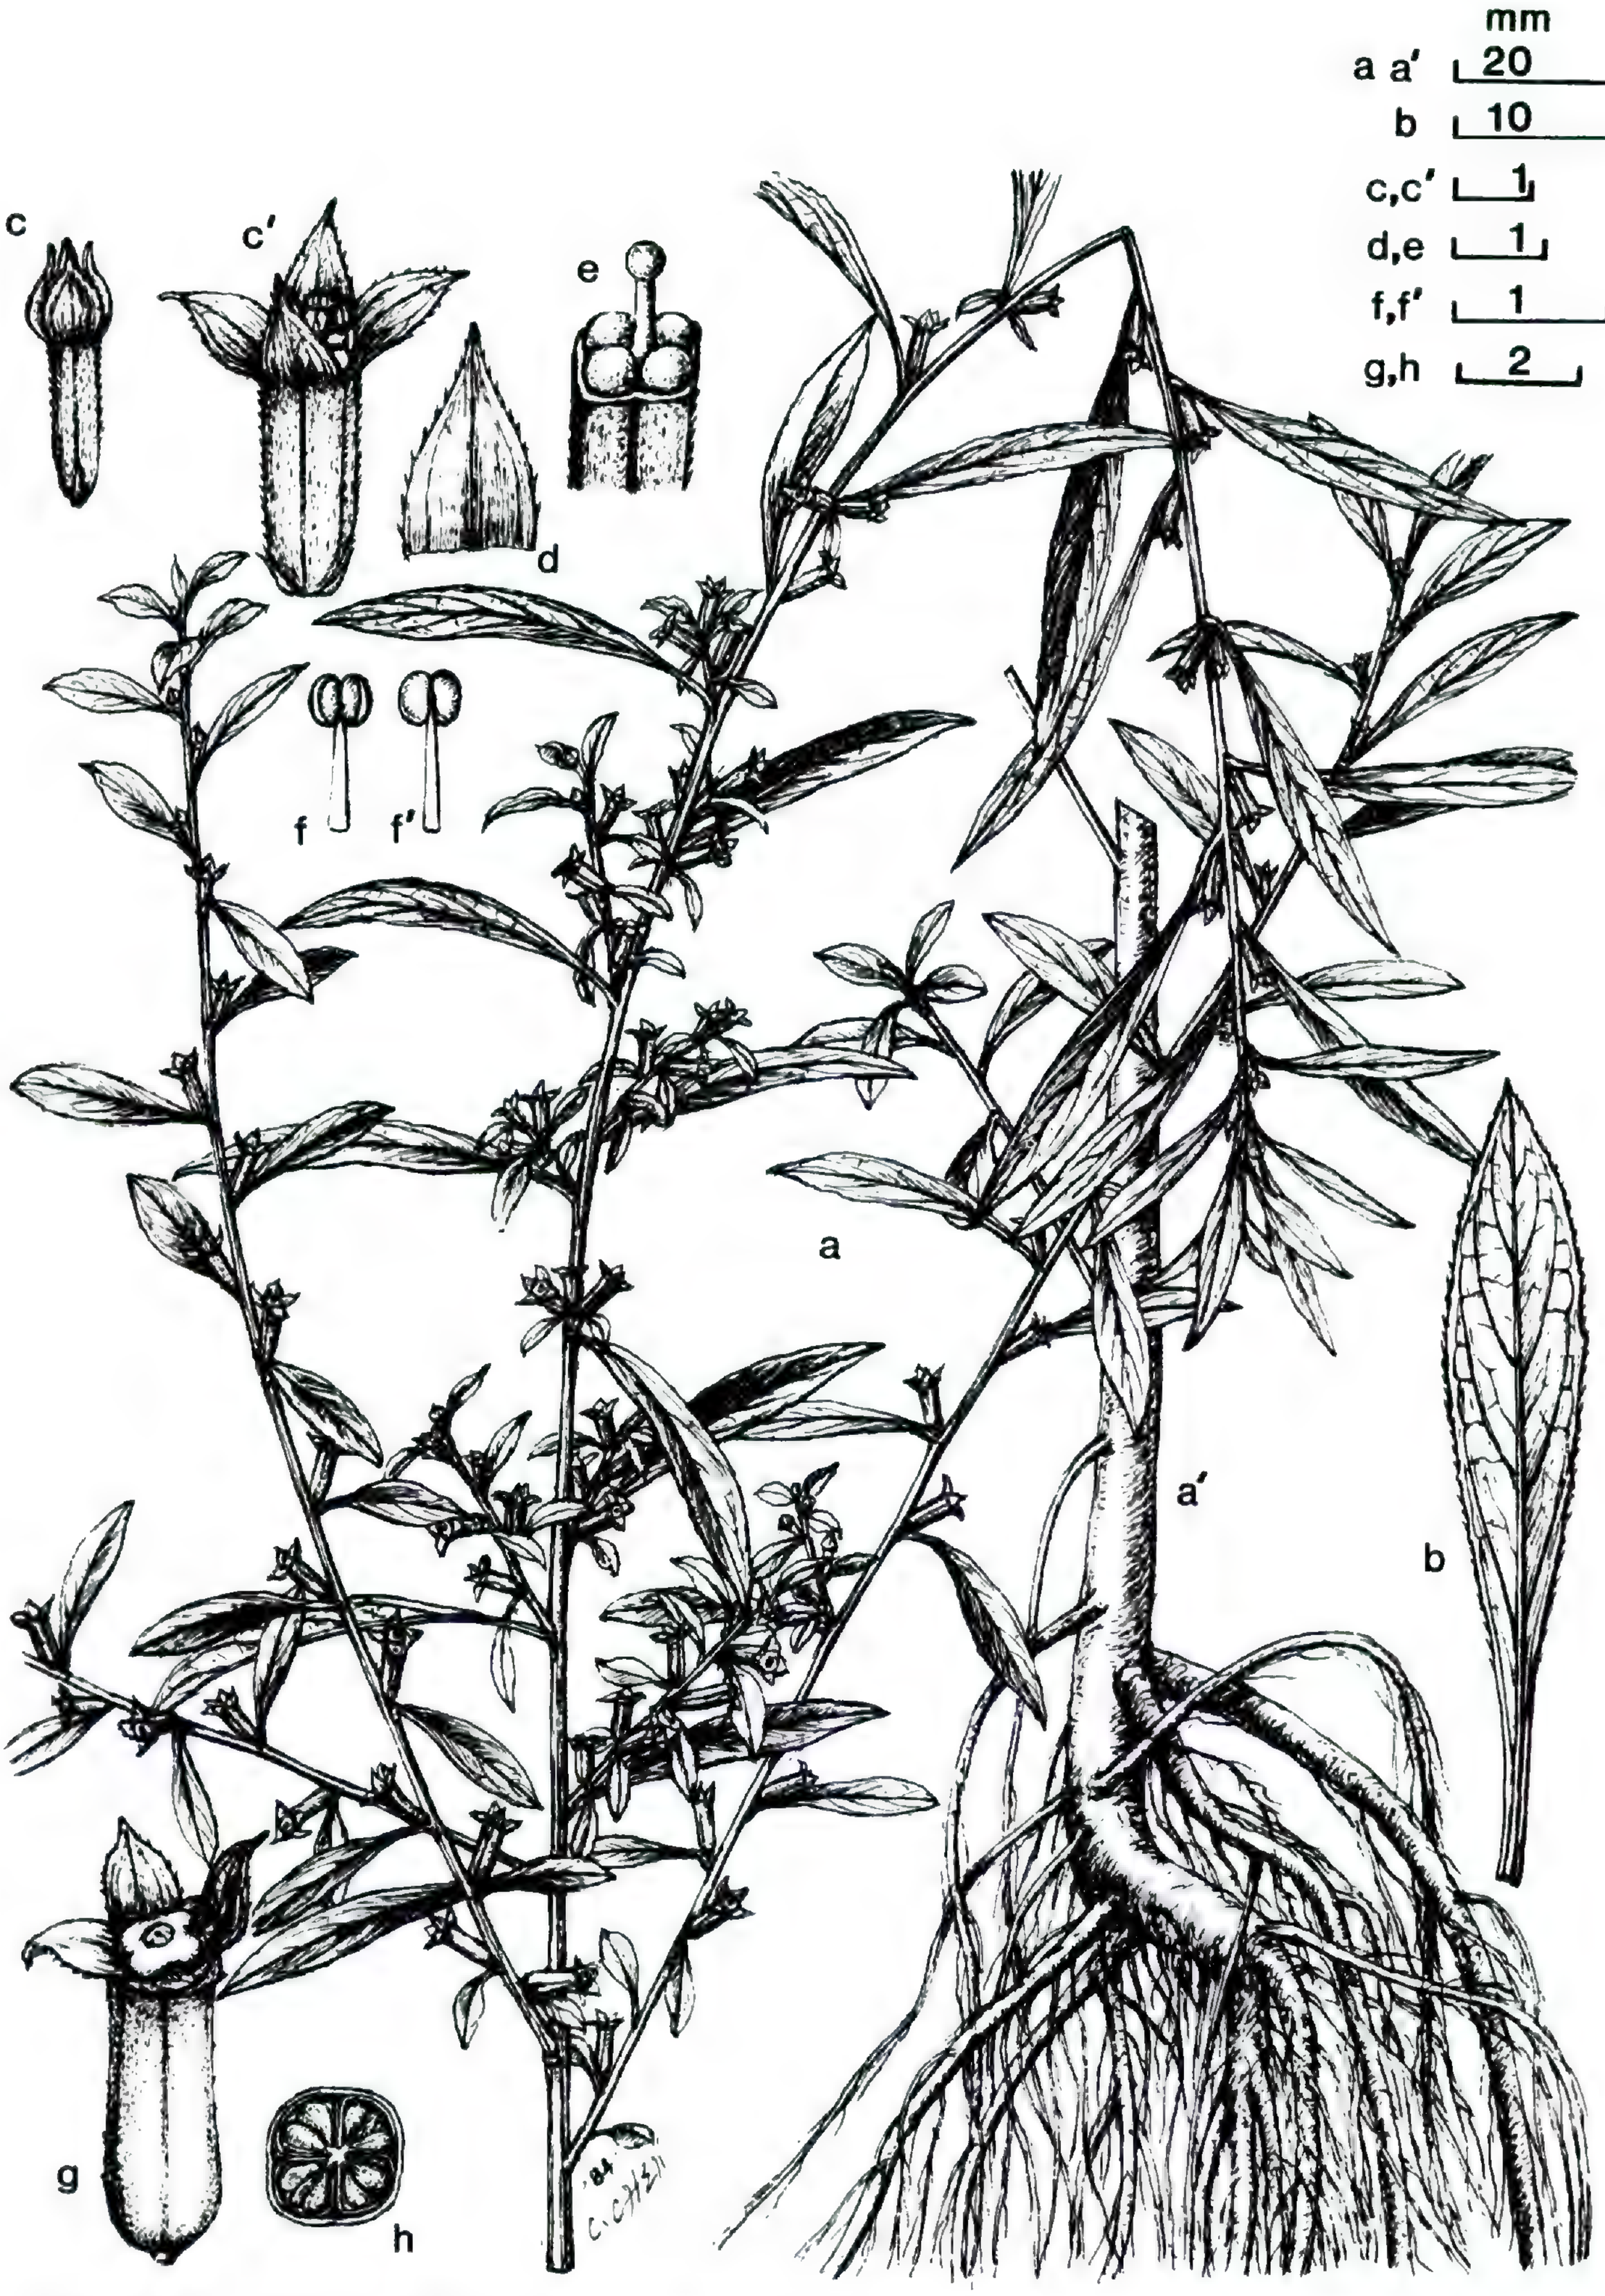

FIGURE 41. *Ludwigia glandulosa* subsp. *glandulosa* (Virginia: Southampton Co., *Fernald & Long 9109*, GH).—a. Habit, upper stem.—a′. Lower stem.—b. Leaf.—c. Flower bud.—c′. Flower.—d. Sepal.—e. Partly dissected flower.—f, f′. Adaxial and abaxial views of stamen.—g. Capsule.—h. Cross section of capsule.

0.35(–0.5) mm long. Bracteoles flanking capsule base or attached up to 2.1 mm above capsule base, rarely on the short pedicel, 0.5–1 mm long, 0.15–0.35 mm wide. Seeds 0.5–0.7 mm long, 0.25–0.35 mm thick, the surface cells oblong, elongate parallel to the seed length. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *L. glandulosa* subsp. *glandulosa* are commonly found in roadside ditches, marshes, pond borders, wet meadows, swales, alluvial floodplains, peaty bogs, moist pinelands, swampy woodlands, and occasionally on waste ground. *Ludwigia glandulosa* subsp. *glandulosa* occurs throughout the Coastal Plain from extreme southeastern Virginia southward through eastern North Carolina, South Carolina, south and central Georgia to the panhandle of Florida and westward across southern Alabama, Mississippi, and Louisiana, reaching its western limit in eastern Texas. To the north, this subspecies extends through extreme southeastern Oklahoma, south and central Arkansas, and up the lower Mississippi basin to southeastern Missouri, central and eastern Tennessee, extreme western Kentucky, southernmost Illinois, and southwestern Indiana. Disjunct populations of *L. glandulosa* subsp. *glandulosa* are found in northcentral Missouri (Fig. 43). Flowering from June to September; fruiting from June to October.

Ludwigia glandulosa is distinctive in being the only tetraploid species in sect. *Microcarpium* with cylindric capsules. The other three species with elongate capsules are the diploid, petaliferous, narrow-leaved *L. linearis*, *L. linifolia*, and *L. stricta*. Raven & Tai (1979) suggested that *L. linearis* is similar to *L. glandulosa* and might be directly related to it. The biosystematic study of Peng (1988), however, demonstrated that the genetic relationship between the diploid *L. linearis* and the tetraploid *L. glandulosa* is not any closer than that between *L. linearis* and other tetraploids. Furthermore, it has been shown that no extant diploids are involved directly in the formation of any tetraploid species in sect. *Microcarpium*.

Ludwigia glandulosa subsp. *glandulosa* is known to occur together with subsp. *brachycarpa*, *L. linearis*, *L. linifolia*, *L. microcarpa*, *L. pilosa*, *L. sphaerocarpa*, and *L. palustris* (sect. *Dantia*) in the field. It has been known to form natural hybrids with all but *L. microcarpa*, an extreme selfer, and the facultatively outcrossing *L. linifolia*. Attempts to synthesize *L. glandulosa* × *L. linifolia* in the experimental greenhouse also failed (Peng, 1988), presumably owing to incompatible genomes. Artificial hybrids between *L. glandulosa* subsp. *glandulosa* and *L. microcarpa*, however, were healthy and floriferous.

Duke (1955) was the first to record a natural hybrid population of *Ludwigia glandulosa* subsp. *glandulosa* × *L. pilosa*, although he did not fully describe the situation he observed. Tetraploid hybrids like this and others are usually fertile and are intermediate in such diagnostic characters as vestiture, sepal and bracteole length, capsule shape and size, seed surface pattern, and whether pollen is shed singly or as tetrads. Triploid natural hybrids involving *L. glandulosa* subsp. *glandulosa* and diploids like *L. linearis* and *L. palustris* may be floriferous but are highly sterile as to pollen and seeds. Their ovaries turn yellowish or pink and dehisce early. *Ludwigia glandulosa* subsp. *glandulosa* (stems erect, leaves alternate) × *L. palustris* (stems prostrate, leaves opposite) generally resembles *L. glandulosa* subsp. *glandulosa* but has slightly broader leaves and smaller flowers. The stems are erect and then prostrate and erect again in some cases; the leaves are alternate like *L.*

glandulosa subsp. *glandulosa*. By contrast, hybrids of *L. glandulosa* subsp. *glandulosa* and *L. linearis* are similar to *L. linearis*, having some yellow petals and narrow leaves. The number of petals on each flower varies from 0 to 4.

4b. Ludwigia glandulosa Walter subsp. **brachycarpa** (Torrey & A. Gray) Peng, Ann. Missouri Bot. Gard. 73: 490. 1986. Based on *L. cylindrica* Elliott β *brachycarpa* Torrey & A. Gray, Fl. N. Am. 1: 524. 1840, non *Jussiaea brachycarpa* Lam., Encycl. 3: 331. 1789. *L. glandulosa* Walter var. *torreyi* Munz, Bull. Torrey Bot. Club 71: 164. 1944, illeg. subst. LECTOTYPE: U.S.A. Texas: Austin Co., San Felipe, "third collection," 1833–1834, *T. Drummond 84* (GH; isolectotypes, GOET, K—2 sheets, W; Peng, Ann. Missouri Bot. Gard. 73: 490. 1986). Figure 42.

Stems sometimes reddish, 10–55(–90) cm tall. Cauline leaves linear-elliptic to linear, sometimes very narrowly elliptic, those on main stem 30–50(–70) mm long, 3–5(–10) mm wide, those on the branches 8–36 mm long, 2–3(–8) mm wide, sessile or with petioles up to 10 mm long. Sepals ovate-deltoid, the apex acute or short acuminate, 1.1–1.9 mm long, 1–1.75 mm wide. Petals 0. Anthers 0.3–0.5 mm long; filaments 0.55–1 mm long. Pollen grains shed as tetrads. Nectary disc obscurely minutely papillose. Style 0.35–0.75 mm long; stigma 0.2–0.35 mm across. Capsules 2–4 mm long, 1.3–2 mm thick, sessile or with pedicels up to 0.15 mm long. Bracteoles flanking capsule base, 0.35–0.75 mm long, 0.1–0.2 mm wide. Seeds 0.55–0.75 mm long, 0.3–0.4 mm thick, the surface cells oblong, elongate parallel to the seed length. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *Ludwigia glandulosa* subsp. *brachycarpa* are usually found along ditches, in low meadows, coastal prairies, seeps in sandy woods, moist sinkholes in granites, and old clay fields. This subspecies occurs along the Gulf coast, from extreme southwestern Louisiana to Nueces County, Texas, and northward through eastern Texas to southcentral Oklahoma (Fig. 43). Flowering and fruiting from April to November.

Representative specimens examined. U.S.A. LOUISIANA: Calcasieu Parish, 1 mi. S of Holmwood, *Ewan 21343* (NO). Cameron Parish, 2 mi. W of jct. of State hwys. 82 & 27, *Peng et al. 4367* (MO). Plants of *Ludwigia glandulosa* subsp. *brachycarpa* occur in the western range of the species and are frequently found in the same county as the typical subspecies, but mixed collections suggesting that they occur side by side are known only in the following: TEXAS: Fort Bend Co., 1 mi. NW of Arcola, water-filled roadside ditch of swampy brushlands, *Raven 19405* (DS, mixed collection of two plants of subsp. *glandulosa* and one plant of subsp. *brachycarpa*; FLAS, subsp. *brachycarpa* only).

Natural hybrid populations between these two subspecies are known in two cases from OKLAHOMA: Atoka Co., ca. 0.25 mi. S of small community of Boehler and SE of Atoka, *Taylor 20332* (VDB), and TEXAS: Galveston Co., ca. 2300 block of Broadway, San Leon, *Waller 3822* (GH). These hybrids are intermediate in stature, leaf shape and size, and (more diagnostically) in fruit size (4–5 mm long) and seed surface (which exhibits a mixture of columnar cells that are elongate, transversely elongate, and sometimes oblique to the seed length).

nardia polycarpa (Short & Peter) Kuntze, Rev. Gen. Pl. 1: 251. 1891. LECTOTYPE: U.S.A. Kentucky: marshes around Louisville, s.d., *H. A. Griswold s.n.* (PH; isolectotypes, DWC, GH, NY, 2 sheets; lectotype here designated). Figure 44.

Plants glabrous. Stems erect, well branched, (10–)25–60(–85) cm tall, the leaf base decurrent and forming ridges 0.15–0.25 mm broad, these sometimes minutely strigillose; aerenchyma well developed on lower stems when submersed. Stolons short, several from the erect stem base, 2.5–15 (–22) cm long, 1–2.3 mm diam., usually seen only in late flowering season, frequently branching from the nodes; internodes short, leaves often clustered on stolon apex and overlapping, narrowly elliptic or oblanceolate, 7.8–20(–32) mm long, 2.4–8 (–12) mm wide, glabrous, the margin entire or remotely denticulate, papillose-serrulate; petioles 0–5 mm long. Cauline leaves very narrowly oblong-elliptic, 35–110 mm long, 4–10(–17) mm wide, the apex narrowly acute or acuminate, the margin entire, densely minutely papillose-serrulate except for the lowest ⅕, this usually smooth, hydathodal glands obscure, the base very narrowly cuneate or long attenuate into winged petiole 1–10 mm long. Stipules dark purplish, narrowly to broadly ovate, succulent, 0.15–0.35 mm long, 0.1–0.25 mm wide. Flowers many, sessile or nearly so in leaf axils, sometimes borne almost to the base of stems; flower-subtending leaves not reduced. Sepals greenish, triangularly ovate, the apex elongate acuminate, spreading horizontally with reflexed tips, 2.5–4.5 mm long, 1.5–3.2 mm wide, glabrous, the margin entire, minutely papillose-serrulate. Petals 0. Anthers 0.5–0.85 mm long; filaments yellowish green, 0.7–1.5 mm long, the base dilated. Pollen grains

FIGURE 44. *Ludwigia polycarpa* (Massachusetts: Franklin Co., 1949, *Delevoryas s.n.*, DS).—a. Habit, upper portion of stem.—a′. Stem base with newly formed stolons.—b. Leaf.—c. Portion of narrowly ridged branch.—d. Portion of branch with mature capsules.—e. Flower bud.—f. Flower.—f′. Partly dissected flower to show stigma, style, and nectary disc.—g, g′. Adaxial and abaxial views of stamens.—h. Sepal.—i. Bracteole.—j. Capsule.—k. Cross section of capsule.

shed as tetrads. Nectary disc yellowish green, raised 0.5–0.75 mm on ovary top, 1.8–3 mm across, 4-lobed, glabrous. Style yellowish green, 0.5–0.8 mm long, glabrous; stigma greenish yellow, cuboid, 0.4–0.8 mm long, distinctly 4-lobed on the apex. Capsules oblong-obovoid with constricted base, obscurely 4-sided with rounded corners, 4–7 mm long, 2.5–5 mm thick, glabrous to obscurely minutely strigillose; pedicels 0.1–0.3 mm long. Bracteoles flanking the capsules, attached 0.5–2.5(–3) mm from capsule base, linear-lanceolate with a swollen base, 3.5–6.5(–8) mm long, 0.4–1(–1.3) mm wide, the margin minutely papillose-serrulate. Seeds light brown, narrowly oblong with curved ends, 0.5–0.6 mm long, 0.2–0.3 mm wide, the surface cells elongate parallel to the seed length. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *Ludwigia polycarpa* grow in ditches; on moist prairie; on alluvial ground of ponds, lakes, and rivers; in marshes; in swales; along edges of lagoons; and in low fallow fields. Contrary to all other species in sect. *Microcarpium*, *L. polycarpa* is centered primarily in the central Midwest, ranging from southcentral Missouri, eastern Kansas, eastern and northeastern Nebraska, northward and eastward across Iowa and southern Minnesota into central Wisconsin and the Upper Peninsula of Michigan. In the east, this species occurs in extreme southern Ontario and the eastern part of the Lower Peninsula of Michigan. *Ludwigia polycarpa* extends southward through western and southern Ohio, northcentral Kentucky, and western West Virginia. Scattered populations occur in central Virginia, southcentral Pennsylvania, Massachusetts, and Connecticut. A highly disjunct, presumably introduced population has been recorded from Kootenai County, Idaho (Fig. 45). Flowering from June to September; fruiting from July to October.

Ludwigia polycarpa is the only species in sect. *Microcarpium* that occurs consistently north of 37°N, in the central Midwest of the United States. The report of Kral (1976) on the range extension of *L. polycarpa* to Covington Co., Alabama (*Kral 40992*, FLAS, GH, MO, NCU, NY, US, USF, VDB), was based on a pure F_1 stand of natural hybrids between *L. pilosa* and *L. glandulosa*.

Ludwigia polycarpa is therefore effectively isolated geographically from all other species in the same section except *L. sphaerocarpa*, which has a wide distribution throughout the Atlantic and Gulf coastal plains, also with scattered populations in the northeastern states as well as around the southern border of Lake Michigan (Fig. 45). Indeed, natural hybridization takes place where geographical isolation is not maintained, as is evidenced by the presence of fertile hybrid populations of *L. polycarpa* × *L. sphaerocarpa* found in Starke Co., Indiana (Peng, 1988). Furthermore, sterile, intersectional hybrids between *L. polycarpa* and the prostrate, opposite-leaved *L. palustris* (sect. *Dantia*), which is very widespread throughout the eastern half of the United States, are found in Ballard Co., Kentucky, the southern border of the range of *L. polycarpa* (Peng, 1988).

Herbarium specimens of *Ludwigia polycarpa* are rarely misidentified due partly to its geographical isolation and partly to its distinctive morphology. Plants of *L. polycarpa* are generally uniform and are characterized by having densely minutely papillose-serrulate leaf margins, elongate-acuminate sepals with reflexed tips, long bracteoles (3.5–6.5(–8) mm) attached above the capsule base, and the oblong-obovoid capsules that frequently exhibit reticulate markings along the rounded corners.

Plants of *Ludwigia polycarpa* produce stolons

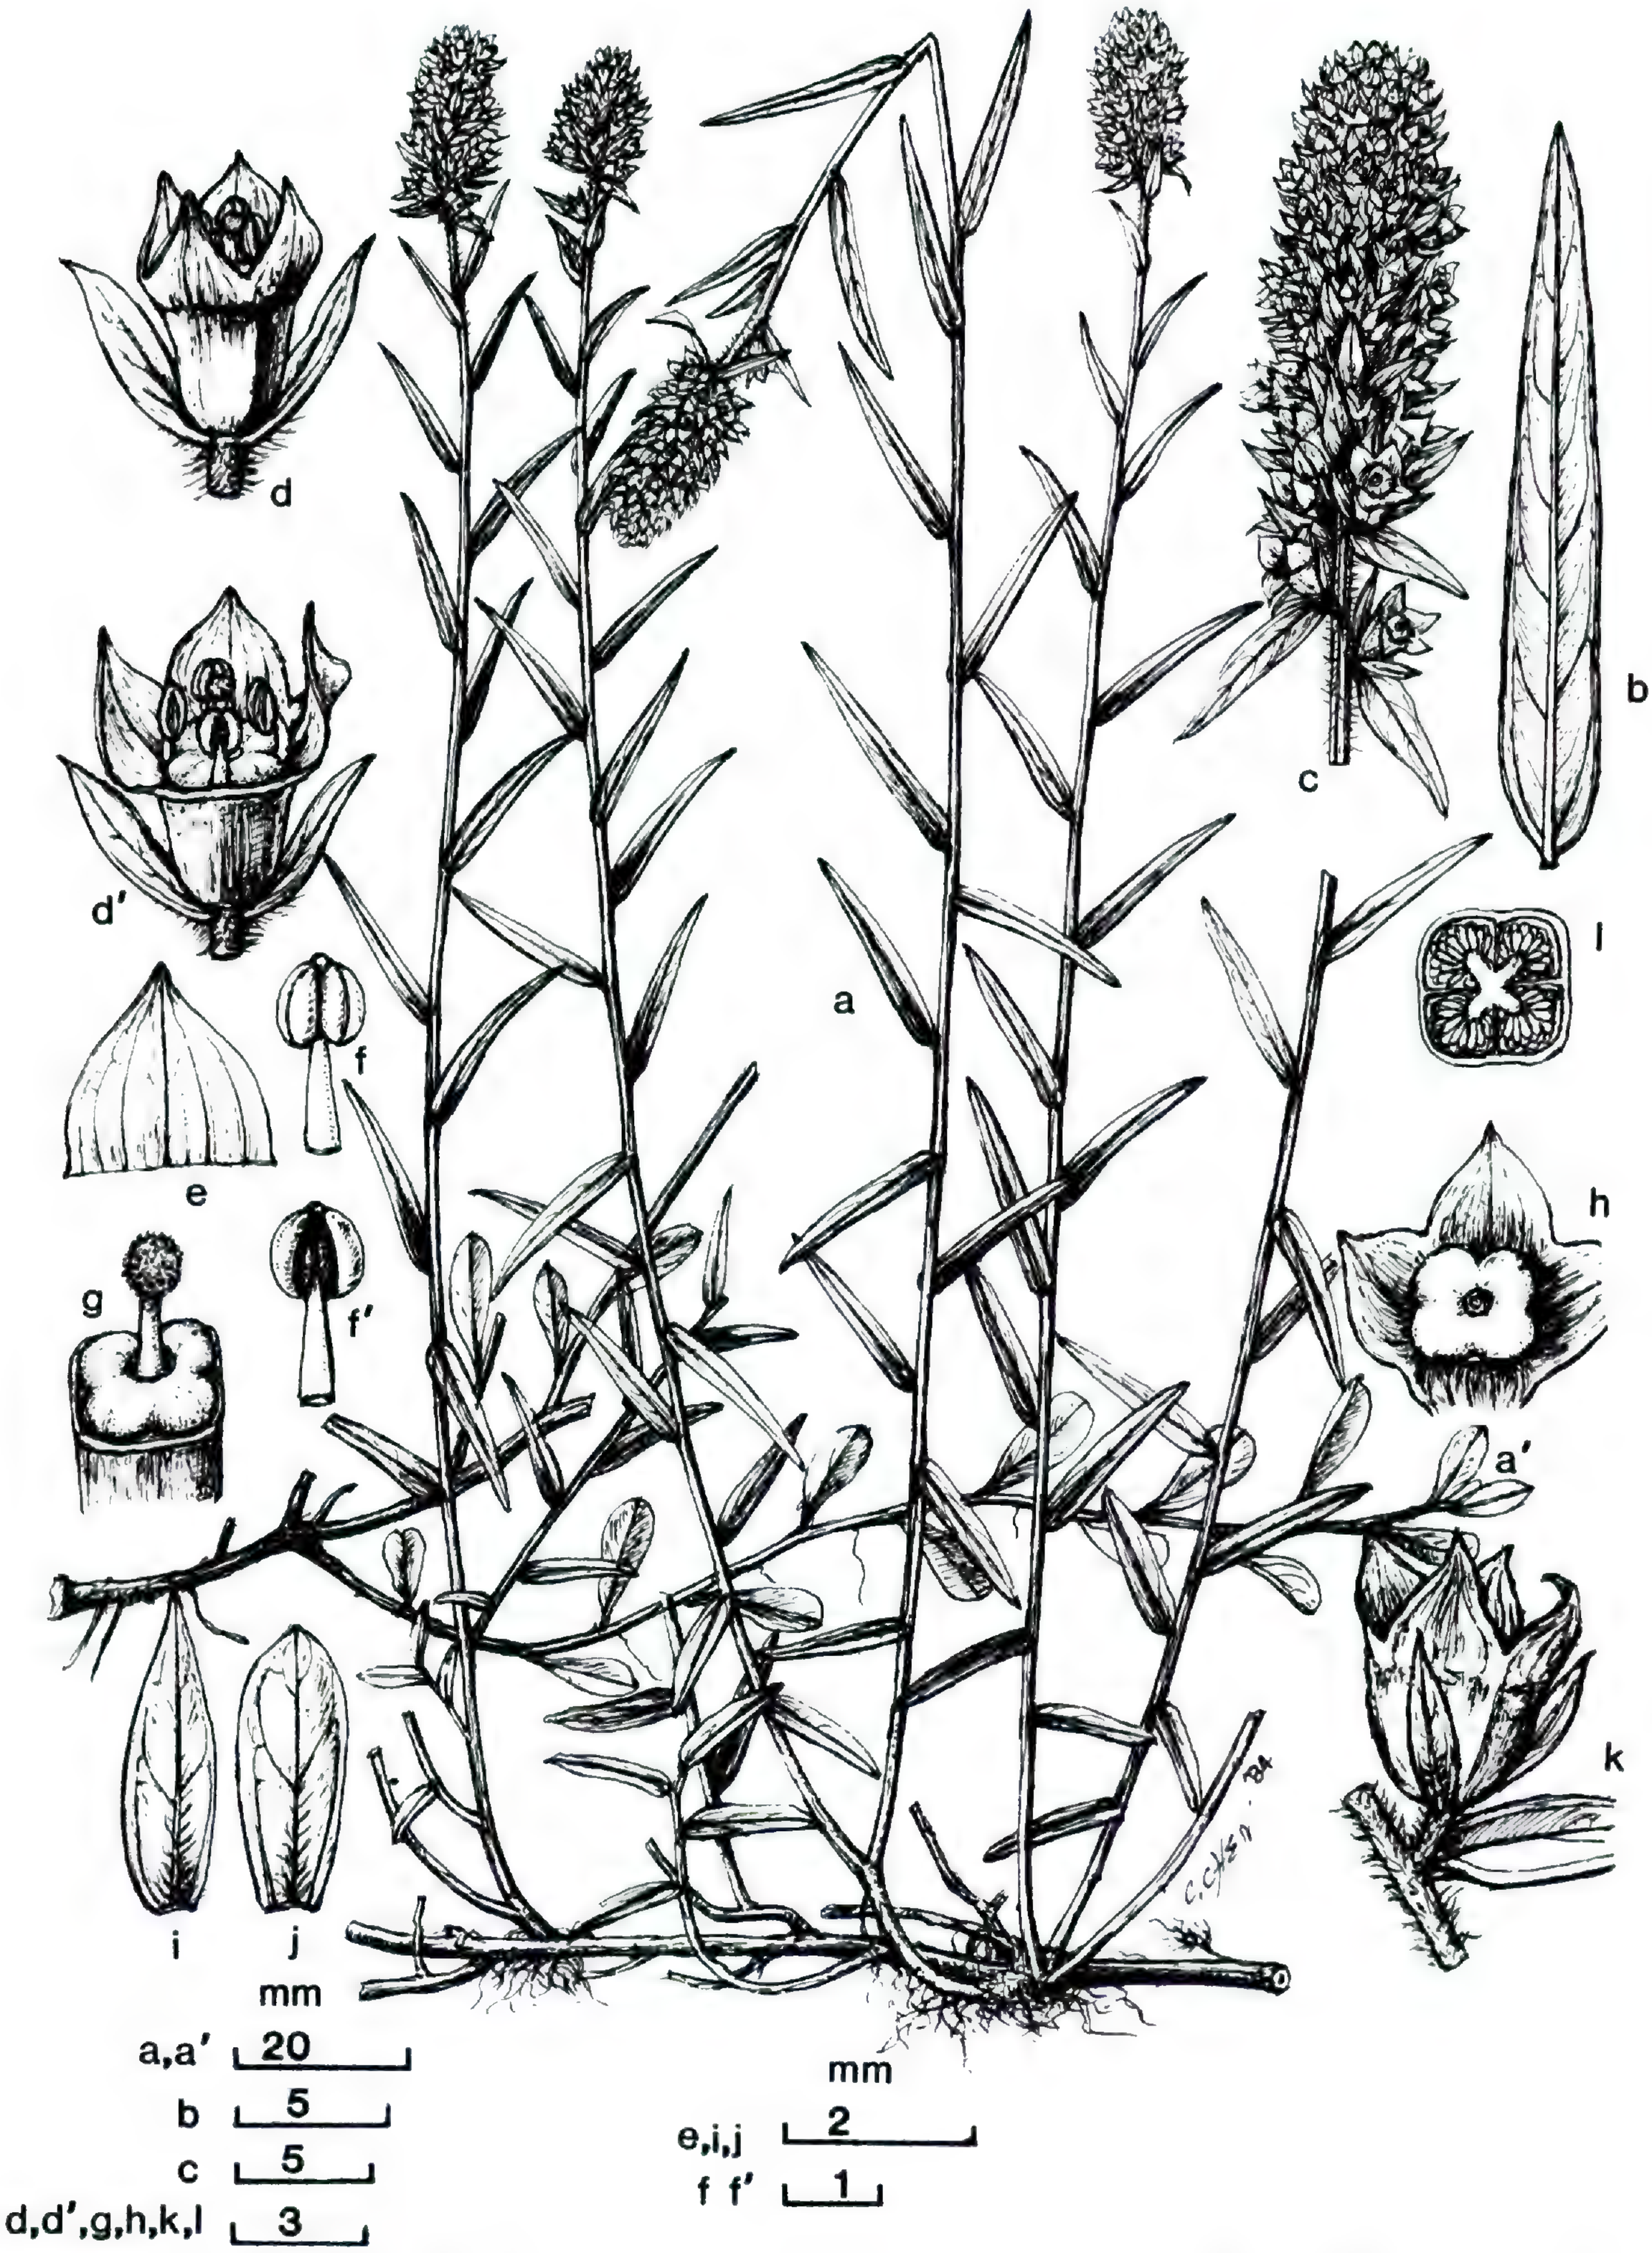

FIGURE 46. *Ludwigia suffruticosa*. All but a′ from Florida (Leon Co., *Godfrey 53576*, DUKE); a′ from Florida (Manatee Co., *Shuey 2024*, FLAS).—a. Habit, erect stems arising from horizontal rhizomes.—a′. Stolon.—b. Leaf.—c. Inflorescence.—d. Flower.—d′. Flower, a sepal removed to show stamens and pistil.—e. Sepal.—f, f′. Adaxial and abaxial views of stamens.—g. Nectary disc and pistil.—h. Nectary disc.—i. Bracteole.—j. Flower-subtending leaf.—k. Capsule.—l. Cross section of capsule.

from their lower nodes in late flowering season, like other species do. Their stolons, however, are much shorter, normally up to 15 cm, and their leaves, unlike those of any other species of sect. *Microcarpium*, are often densely congested and overlap at the apex of the sparsely leaved stolons. The modified stolon is comparable to the perennating turion of *Epilobium* (Keating et al., 1982), which apparently serves as an adaptation to the severe winter that plants of *L. polycarpa* have to endure in the northern states.

The short stolons are occasionally found growing from the nodes of aerial stems that have fallen to the ground. Such specimens include:

U.S.A. ILLINOIS: Riverside, *1886, Ohlendorf s.n.* (F): Western Springs, *Smith 676* (F). MISSOURI: Saline Co., Blackwater River, Sect. 32, 5 mi. NW of Ridge Prairie, *Steyermark 21527* (MO).

6. Ludwigia suffruticosa Walter, Fl. Carol. 90. 1788. *Isnardia suffruticosa* (Walter) Kuntze, Rev. Gen. Pl. 1: 251. 1891. *Ludwigia capitata* Michaux, Fl. Bor.-Am. 1: 90. 1803, nom. illegit., based on *L. suffruticosa* Walter. *Isnardia capitata* (Michaux) DC., Prodr. 3: 60. 1828. TYPE: U.S.A., "the Carolinas," s.d., *T. Walter* (type not seen, not located at BM). Figure 46.

Plants bearing rhizomes and stolons. Stems erect, unbranched or slightly branched, (16–)30–90 cm tall, glabrous except for the rachis and stem base, these often puberulous to densely hirtellous, the hairs 0.2–0.6(–0.8) mm long, aerenchyma in the lower part very rarely seen. Rhizomes 1–several, 6–55 cm long, 1.25–4.5 mm thick, often branched, glabrous to densely hirtellous, the leaves dark purplish, minute, scalelike, oblate or suborbicular, ca. 0.3–0.6 mm long, 0.6–0.9 mm wide, appressed. Stolons less commonly seen than rhizomes, 8–80 cm long, 1.1–2.2 mm thick, branched, glabrous to densely hirtellous, the leaves purplish, oblong or oblanceolate-elliptic to spatulate, 4–35 mm long, 1.6–15 mm wide, glabrous to pilose, the petioles 1–6 mm long. Cauline leaves green, lance-elliptic, lance-linear to linear, the lower ones shorter, oblong-oblanceolate to oblong or oblong-lanceolate, 25–95 mm long, (1–)3–9 mm wide, glabrous to ± pilose on those at stem base/peduncles, the apex manifestly elongate tapering into a sharp point or acute on lower leaves, the margin entire, hydathodal glands usually obscure, submarginal veins parallel to the midvein often prominent on the abaxial surface, the base rounded or obtuse, sessile. Stipules deltoid, 0.25–0.45 mm long, 0.15–0.4 mm wide. Flowers in racemose inflorescence 1–5(–12) cm long, 1–2 cm wide, terminal on the stems or branches; the subtending leaves much reduced and bractlike, lanceolate or lance-elliptic, 4–12(–18) mm long, 1.35–3.5(–4) mm wide, glabrous to hirtellous along margin and venation of the abaxial surface, especially on the lower half. Sepals whitish, broadly ovate or deltoid, ascending, 2.3–3.5(–4) mm long, 2.3–3.2(–3.8) mm wide, glabrous, apex acuminate, margin entire, base connate 0.6–1 mm above the ovary. Petals 0. Anthers 0.75–1(–1.3) mm long; filaments pale yellowish, 1.2–2 mm long, distinctly dilated toward the base. Pollen grains shed as tetrads. Nectary disc yellowish, raised 0.5–0.6 mm on top of the ovary, 1.8–3.1 mm across, the lobes obscure, glabrous. Style pale yellowish, 0.9–1.7 mm long, glabrous; stigma whitish, 0.4–0.75 mm long, 0.5–0.75 mm thick, distinctly 4-lobed on the apex. Capsules broadly obpyramidal with rounded corners, sometimes subspherical, 2.5–4.25 mm long, 2.5–4.5(–5) mm thick, glabrous or in a few cases minutely strigillose, the hairs ca. 0.05–0.1 mm long, pedicels 0.5–1.5(–2) mm long. Bracteoles flanking capsule base or on the short pedicel, 3.5–5(–6) mm long, (1.2–)1.4–2 mm wide, glabrous to pilose without, glabrous within. Seeds brown, elliptic oblong, curved on both ends, 0.5–0.6 mm long, 0.2–0.25 mm thick, surface cells nearly isodiametric. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *L. suffruticosa* grow in sandy ditches, along river marshes, in meadows, in limestone sinks, in cypress swamps, and in moist pinelands. This species occurs along the Atlantic coast from southeastern North Carolina through eastern South Carolina, southern Georgia, and throughout the northern three-quarters of the Florida peninsula. To the west this species occurs through most of the Florida panhandle, extreme southeastern Alabama, and southern Georgia (Fig. 47). Flowering from May to September; fruiting from June to October.

Ludwigia suffruticosa is a very distinct species that has many features unique within sect. *Microcarpium*. Its leaves are rounded to obtuse at the base and clearly sessile. It has a very compact, racemose inflorescence at the very top of each erect stem, as is suggested by the name "*Ludwigia capitata*," an illegitimate synonym of *L. suffruticosa* Walter, coined by Michaux (1803). The stems are usually single or occasionally with one or two or more branches arising directly beneath the main inflorescence. These branches always rise above the main inflorescence and are each terminated by a smaller compact raceme. Furthermore, each flower is usually subtended by a reduced, bractlike leaf in addition to the bracteoles that flank the ovary. It is also the only species in sect. *Microcarpium* that perennates mainly by underground rhizomes. Stolons that float or send roots into mud, prevalent in many other species, are not common in *L. suffruticosa*. It is especially peculiar in having variously pubescent inflorescences and lower stems, stolons, and underground rhizomes but is otherwise completely glabrous in the middle—see below.

The flowers of this species are characteristically very compactly arranged into a raceme up to 5 cm long. The following specimens examined, however, have less compact and longer inflorescences but are otherwise typical of *Ludwigia suffruticosa*:

U.S.A. FLORIDA: Charlotte Co., Caloosa Forest/Expt. Area, Pasture 8, *Parrott 219* (DUKE, inflorescences 7 cm long). Hillsborough Co., Tampa, Gates Dr., in sandy field W of Gates Apts., *Dille 424* (MO, inflorescences up to 12 cm long, co-occurring with normal, compact-inflorescenced individuals (same locality, *Dille 423*, MO). GEORGIA: Wayne Co., in very sandy soil SE of Lindy's bluff, just NE of Jesup, *Dunkan 3759* (GH, inflorescences 8 cm long; NCU, inflorescences 10.5 cm long).

The distribution pattern of pubescence in plants of *Ludwigia suffruticosa* is peculiar and variable. The plants range from being completely glabrous to densely, minutely hirtellous with multicellular hairs up to 0.6(–0.8) mm long on rhizomes, stolons, stolon leaves, stem base, and basal leaves of the lower plant body and peduncles, pedicels, flower-subtending leaves, and bracteoles of the upper part but are completely glabrous in the middle part of the plant body. The capsules are usually completely glabrous. In the following specimens, however, erect, microscopic protuberances ca. 0.02–0.1 mm long are found evenly but not densely distributed on the fruit wall:

U.S.A. FLORIDA: Gilchrist Co., in swamps 4 mi. E of Trenton, 1940, *West & Arnold s.n.* (FLAS). Hillsborough Co., Tampa, Gates Dr. in sandy field W of Gates Apts., *Dille & Dille 424* (MO); in wet ground along SR-581, ca. 5 mi. N of Tampa, *Funk 72*; *Gregory 46*; *Kuczynski 48*; *Robbins 130*; *Rose 11*; *Willett 10* (all USF). Leon Co., bordering Lake Jackson on NW side, just N of route

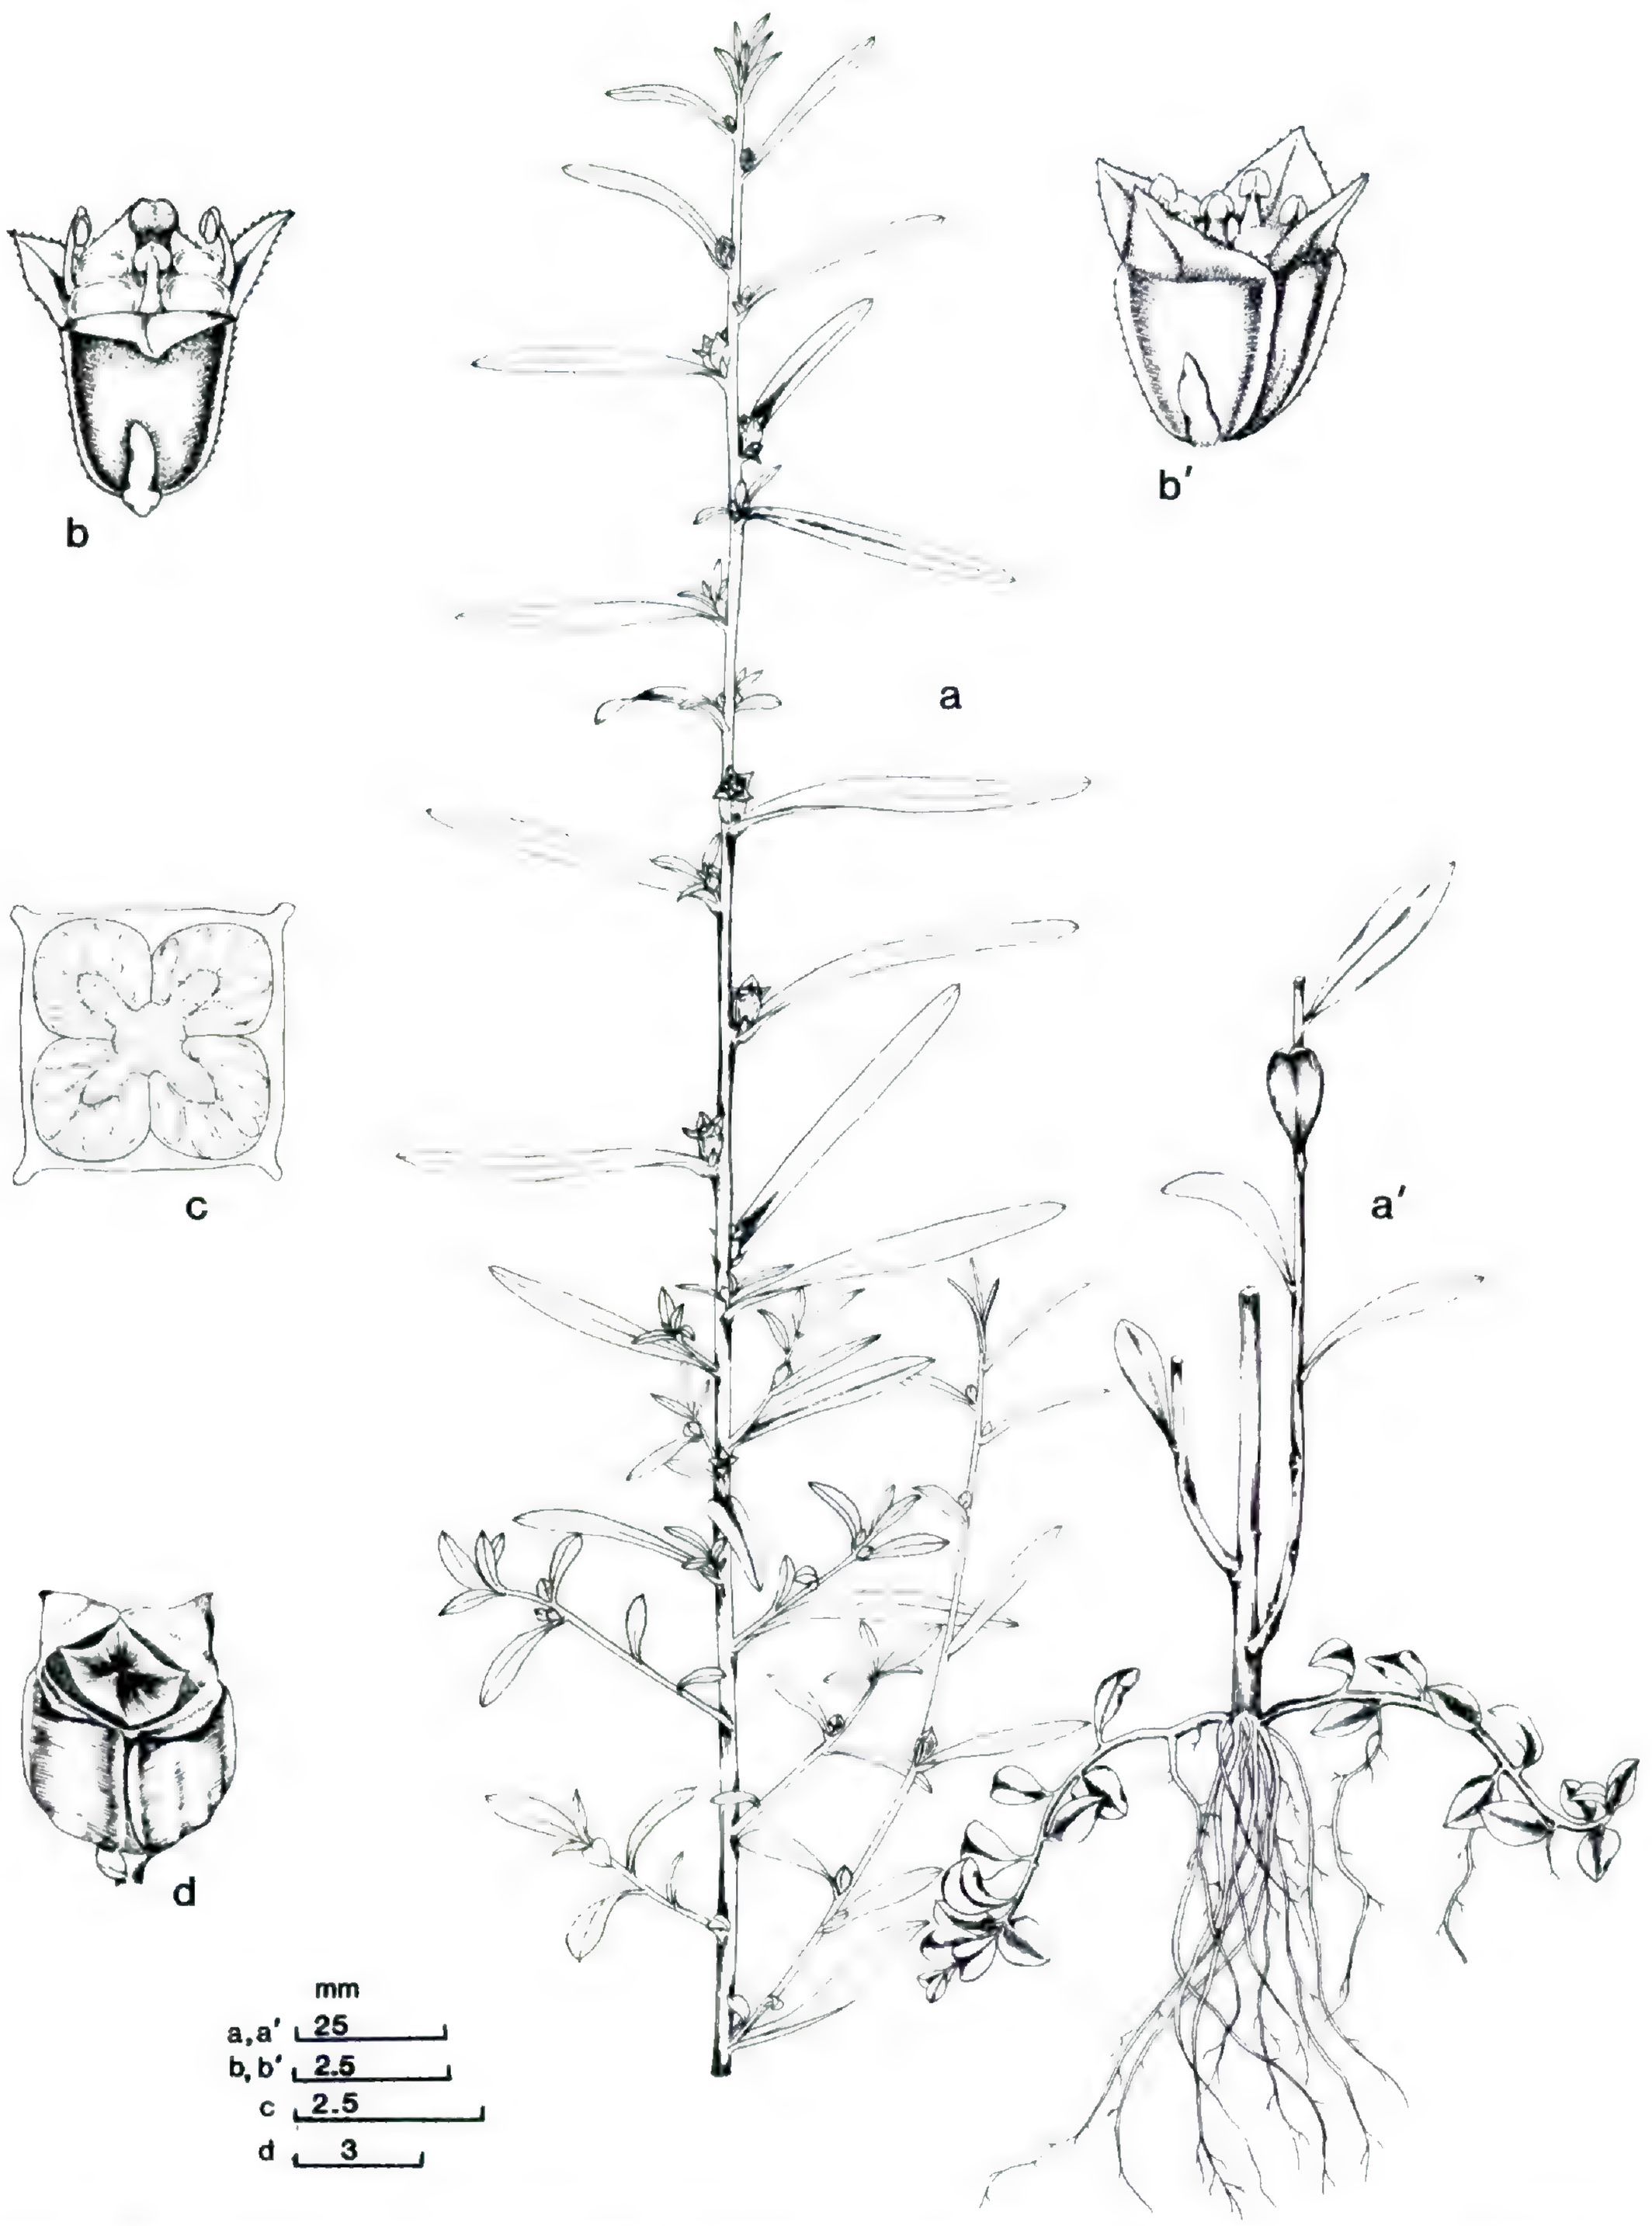

FIGURE 48. *Ludwigia lanceolata* (Florida: Highlands Co., *Peng et al. 4193*, MO).—a. Habit, erect stem.—a′. Stem base with stolons.—b, b′. Flower.—c. Cross section of capsule.—d. Dehiscent capsule.

27, NW of Tallahassee, *Anderson 4497* (GA, MO); on FL 363, 3 mi. N of Woodville, *Dille & Dille 421* (MO); Lake Jackson, adjacent to US 27, *Faircloth 246* (MO, NCU); shores of small pond, 6 mi. S of Tallahassee, *Godfrey 53576* (DUKE, FLAS, NCU, NY, SMU, USF, VDB); wet sands, exposed shores of sinkhole pond, by Spring Hill Rd., S of Tallahassee, *Godfrey 76066* (FSU); along US 319, ca. 5 mi. S of Tallahassee, *Henderson 63-1683* (TEX); margin of a small lake, along FL 271, ca. 5 mi. S of Tallahassee, *Henderson 67-1455* (VDB); near Lake Jackson, 8 mi. NW of Tallahassee, 1940, *Hocking s.n.* (FLAS). Orange Co., *Godfrey 57330* (FSU).

Polk Co., margin of a small lake, SE of Hesperides, ca. 8 mi. E of Lake Wales, off number 60, *Lakela 24806* (DS).

In a specimen collected from Florida (Leon Co., 4 mi. S of Tallahassee, on Rt. 369, 1950, *Sargent s.n.* (GA)) the capsule wall is minutely pilose with hairs ca. 0.4 mm long.

The sepals of *Ludwigia suffruticosa* are normally glabrous, but in the following specimen the sepals are minutely pilose:

U.S.A. FLORIDA: Duval Co., vicinity of Mayport & Jacksonville, 1870–1876, *Keeler s.n.* (NY).

Ludwigia suffruticosa, *L. alata*, *L. pilosa*, and *L. sphaerocarpa* are the species in sect. *Microcarpium* that do not undergo mechanical self-pollination. With its whitish creamy sepals, which are very showy in the dense flower aggregates, the cross-pollinating *L. suffruticosa* successfully attracts many insects, mostly bumblebees, honeybees, and wasps. It occurs with at least four species of *Ludwigia* (*L. alata*, *L. linearis*, *L. lanceolata*, and *L. pilosa*) in the field, hybridizing with all but *L. linearis*. These results are mirrored in the biosystematic study (Peng, 1988): artificial hybrids between *L. linearis* and *L. suffruticosa* are weak and inviable, whereas the other combinations that occur in nature have been synthesized successfully and were very vigorous in the experimental greenhouse.

Remarks on natural hybrids between *Ludwigia suffruticosa* and either *L. alata* or *L. lanceolata* are provided in the accounts of *L. alata* and *L. lanceolata*. Natural hybrid populations of *L. suffruticosa* × *L. pilosa* have previously been given a varietal status within *L. suffruticosa* (as *L. capitata* Michaux *β pubens*) by Torrey & Gray (1840), which was subsequently and incorrectly considered to be a synonym of *L. pilosa* by Munz (1944, 1965). The hybrids are densely hirtellous throughout, but the hairs are not as long as those of *L. pilosa*, and the sepals are neither cuspidate nor elongate-acuminate, but rather acuminate. Further, their stems are not well branched, their leaves are often long and narrow, their flowers are in more or less congested racemes on the upper part of the stem or branch, and the leaves that subtend their flowers are slightly reduced and bractlike. The combination of these characteristics clearly suggests that such plants represent hybrid populations of *L. suffruticosa* × *L. pilosa*. The possibility that *L. ravenii*, the only species other than *L. pilosa* that is consistently densely hirtellous, was involved in their parentage is reduced because it is rare and not known to occur with *L. suffruticosa*. Furthermore, the seed surface of the hybrid plants consists of subisodiametric cells, a characteristic of both *L. suffruticosa* and *L. pilosa*, but not of *L. ravenii*.

7. **Ludwigia lanceolata** Elliott, Sketch Bot. S.C. & Ga. 1: 213. 1817. *Isnardia lanceolata* (Elliott) DC., Prodr. 3: 61. 1828. TYPE: U.S.A. Georgia: in swamps, s.d., *J. E. Leconte s.n.* (holotype, CHARL; photographs, GH, MO; isotypes, P, PH). Figure 48.

Plants glabrous. Stems often brownish purple, erect, leafless below, branched above, 45–100 cm tall; aerenchyma well developed in lower stems when submersed in water; leaf bases slightly decurrent along the stems. Stolons up to 40 cm long, 2 mm thick, the leaves remote, 1–3 cm apart, purplish, rotund or elliptic to broadly elliptic, 5–27 mm long, 6–12 mm wide, apex rounded, obtuse or acute, base attenuate into winged petioles 2–10 mm long. Cauline leaves dark green, the lower ones sometimes purplish, leaves on the main stem elliptic, oblanceolate or narrowly oblanceolate, those on the branches usually much reduced, ranging from narrowly elliptic to very narrowly elliptic or linear; in general, leaves 20–75 mm long, 2–7.5 (–14) mm wide, apex acute to narrowly acute, margin entire with minute hydathodal glands, base narrowly cuneate or sometimes attenuate into a winged petiole up to 5 mm long. Stipules dark reddish purple, ovate to very widely ovate, succulent, 0.2–0.45 mm long, 0.15–0.25 mm wide. Flowers in upper leaf axils. Sepals greenish, shallowly triangular or deltate, ascending, 1.5–2.5 mm long, 1.8–3.3 mm wide, glabrous, apex acute to acuminate, minutely papillose along the margins. Petals 0. Anthers 0.4–0.6(–0.75) mm long; filaments nearly translucent, 1–1.4 mm long, dilated toward the base. Pollen grains shed as tetrads. Nectary disc yellowish green, raised 0.4–0.6 mm on ovary apex, 1.75–2.6 mm across, 4-lobed, glabrous. Style yellowish green, 0.5–0.7 mm long, glabrous; stigma yellowish, subglobose, 0.3–0.5 mm long, 0.7–1 mm thick. Capsules obpyramidal, winged on the corners, 3.5–5 mm long, 2.5–4.5 mm thick (as measured from wing to wing), glabrous, occasionally minutely strigillose, the wings 0.3–0.7 mm wide, usually minutely strigillose; pedicels up to 0.5 mm long. Bracteoles located at or slightly above capsule base and on 2 sides, variable in shape and size even in the same plant, ovate-elliptic to very narrowly elliptic, 1.5–4.3 mm long, 0.4–1.4 mm wide, margin minutely papillose, often with a distinct, rounded, swollen tissue 0.5–1 mm

FIGURE 49. Distribution of *Ludwigia lanceolata*.

across below the point of attachment. Seeds light brown, narrowly oblong with constricted ends, 0.65–0.75 mm long, 0.25–0.3 mm wide, the surface cells nearly isodiametric. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *Ludwigia lanceolata* grow in ditches, low meadows, cypress swamps, moist pinelands, edges of pocosins, and on sandy peaty soil. This is a fairly uncommon species, with scattered populations occurring along the Atlantic coast of southern North Carolina, South Carolina, eastern and southern Georgia, and the Florida peninsula. This species reaches its western limit in the central panhandle of Florida (Fig. 49). Flowering from June to October; fruiting from June to November.

Representative specimens examined. U.S.A. FLORIDA: Brevard Co., Okeechobee region, *Fredholm 5987* (GH, MO, NY, US). Columbia Co., Lake City, *Nash 2502* (E, F, GH, MO, MSU, NY, US). TABLE 5. Comparison of *Ludwigia alata* with *L. lanceolata*.

Characters	*L. alata*	*L. lanceolata*
Stems	Often winged, sometimes obscurely so	Nearly smooth
Sepal		
Color	Whitish adaxially	Greenish adaxially
Length	Subequal to capsule	Shorter than capsule
Anther length (mm)	0.55–0.9	0.4–0.6(–0.75)
Filament length (mm)	1.1–1.7	1–1.4
Pollen grains shed	Singly	In tetrads
Nectary disc width (mm)	2–3.3	1.75–2.6
Style length (mm)	0.8–1.3	0.5–0.7
Breeding system	Obligate outcrossing	Modally autogamous
Capsule wall between the winged corners	Bulging out longitudinally in the central part	Smooth
Seed length/width ratio	Ca. 2	Ca. 2.4–2.8
Surface cells	Columnar	Suborbicular
Chromosome number	$n = 24$	$n = 16$

Cox Road, *Bozeman 2176* (FLAS, GA, NCU). NORTH CAROLINA: New Hanover Co., near Wilmington, 1867, *Canby s.n.* (NY). SOUTH CAROLINA: Beaufort Co., Bluffton, *Mellichamp s.n.* (NY).

Ludwigia lanceolata is interfertile with all seven other tetraploid members of sect. *Microcarpium*. However, it is most similar to the hexaploid *L. alata* in general aspects and fruit morphology, and is suspected to have been one of the parents of that species (Peng, 1988). For a detailed discussion of these two species, see remarks under *L. alata* and Table 5.

Ludwigia lanceolata has been found growing with *L. pilosa*, *L. suffruticosa*, both tetraploids, and with the diploid *L. linearis*. *Ludwigia alata* and *L. lanceolata* have not been found growing together, although they have overlapping ranges in the eastern and central Florida panhandle. It is worth noting that, although both species occur in generalized, wet habitats, such as the borders of ditches, ponds, and swamps, *L. lanceolata*, unlike *L. alata*, is not found in the limestone prairies and brackish marshes that prevail in the Everglades region of southern Florida. No hybrids have been observed, but they would be very difficult to detect without measuring pollen stainability or determining chromosome numbers.

Ludwigia lanceolata intergrades with *L. pilosa*, and fertile hybrids between them are frequent in nature. Such hybrids were named *L. simulata* by Small (1903). The type at NY (West Florida, *Biltmore Herbarium*) shows a combination of densely strigillose hairs and four-angled or barely winged capsules; it apparently arose following hybridization between a parent with strongly winged capsules (*L. alata* or *L. lanceolata*) and one that was pubescent (*L. pilosa*, *L. ravenii*, or *L. sphaerocarpa*). The isodiametric seed surface cells, combined with the fact that these plants shed their pollen grains as tight tetrads clearly suggest *L. lanceolata* and *L. pilosa* as the parents. Two other collections identified as this hybrid are also from Florida:

U.S.A. FLORIDA: Franklin Co., Apalachicola, *Chapman s.n.* (F, US). Highlands Co., Bear Point, Lake Childs, *Brass 15532* (GH, US).

Ludwigia lanceolata also intergrades with *L. suffruticosa*. For example, putative parents and introgressed hybrid populations were found in the same sandy ditch by a prairie in Hillsborough Co., Florida (*Peng 4324*, *4328*, MO). The leaves of the hybrids were narrow like those of *L. suffruticosa*, but the stems were well branched above the middle. The flowers are produced in somewhat congested racemes at the top of each branch, and the capsules were obpyramidal and weakly four-angled. *Peng 4324* had 85% stainable pollen and formed 16 bivalents in meiosis.

8. **Ludwigia alata** Elliott, Sketch Bot. S. C. & Ga. 1: 212. 1817. *Isnardia alata* (Elliott) DC., Prodr. 3: 61. 1828. LECTOTYPE: U.S.A. South Carolina: Charleston Co., found in damp places on Sullivan's Island, in the wooded part of the island, July–Sep., s.d., *S. Elliott s.n.* (PH; no authentic material found in Elliott's herbarium at CHARL, so sheet from PH selected as lectotype). Figure 50.

Plants glabrous. Stems erect or somewhat sprawling, 40–120(–160) cm tall, branched above, aerenchyma distinct in lower parts when sub-

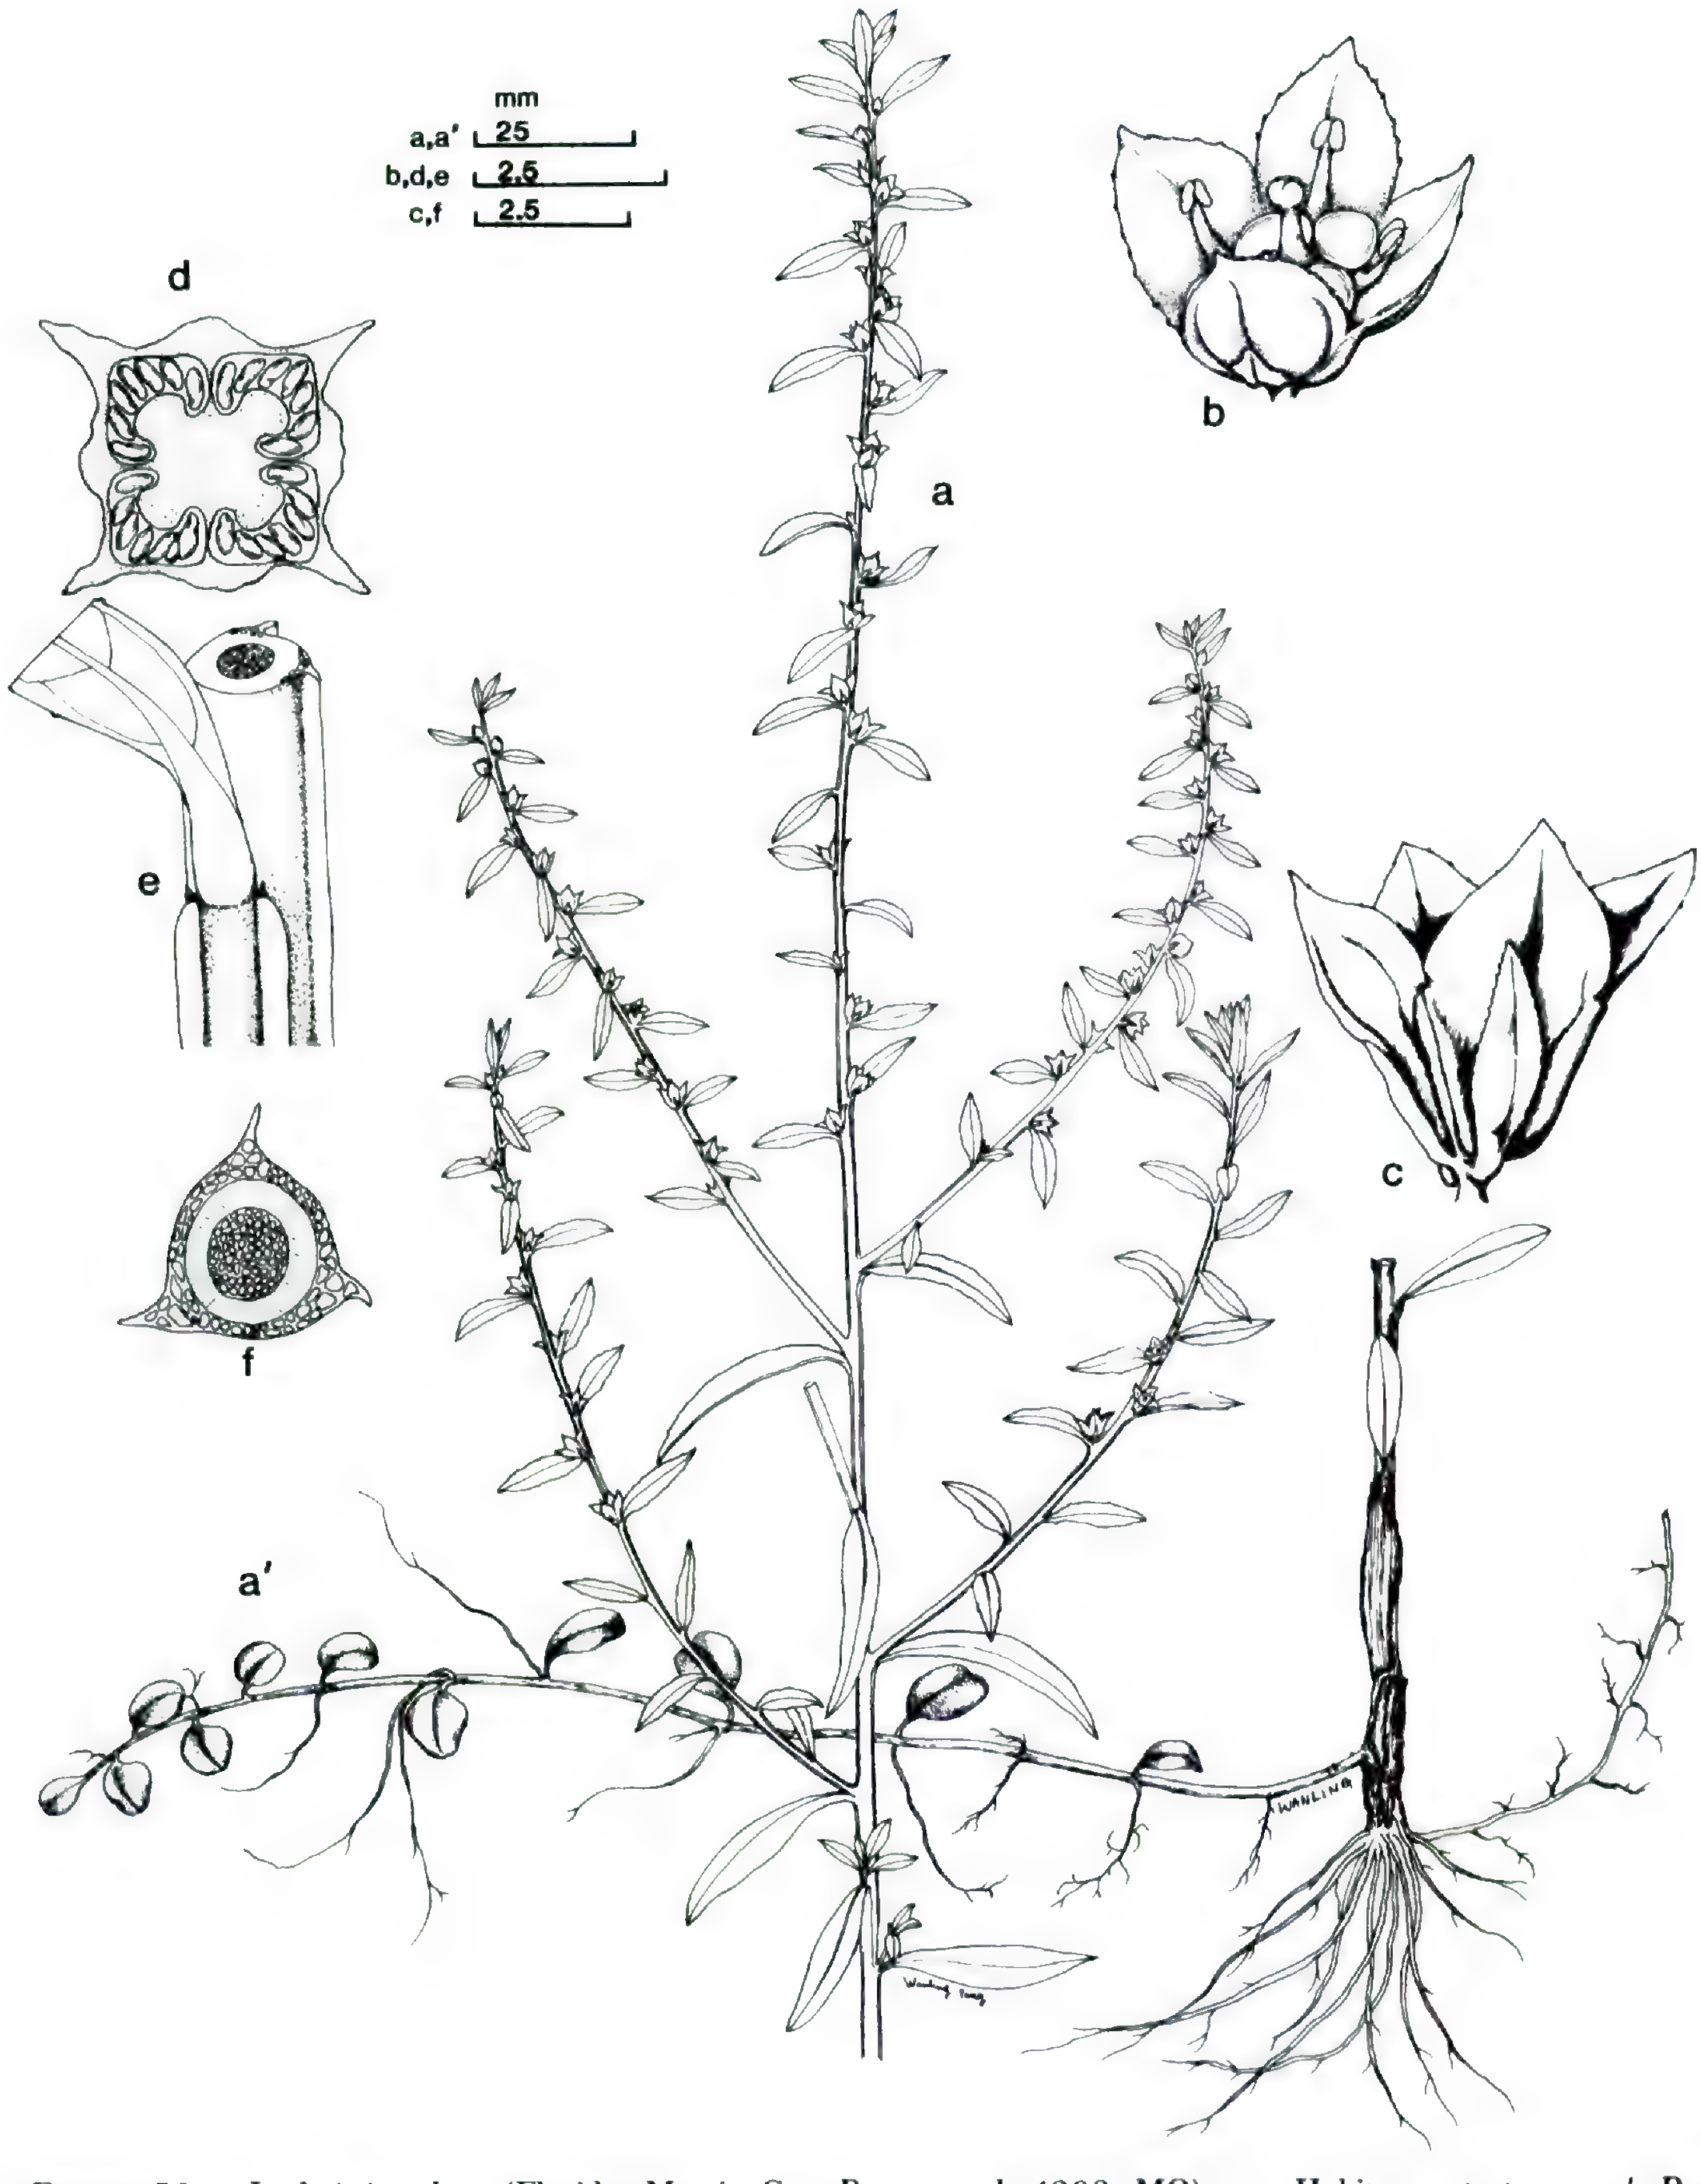

FIGURE 50. *Ludwigia alata* (Florida: Martin Co., *Peng et al. 4203*, MO).—a. Habit, erect stem.—a'. Basal stolon.—b. Flower.—c. Capsule.—d. Cross section of mature capsule.—e. Branch, showing decurrent leaf base.—f. Cross section of stem.

mersed, slightly to distinctly winged, the wings up to 1.8 mm broad. Stolons several from lower nodes, often seen in the flowering season, 8–65(–95) cm long, 0.7–2.5 mm diam., the leaves often purplish, especially on the abaxial surface, variable in shape, ranging from orbicular, rotund, oblanceolate to (broadly) elliptic, 4–26 mm long, 4–15 mm wide, base attenuate into petioles 1.5–10 mm long. Cauline leaves lance-elliptic, very narrowly elliptic to linear (those of lower stems sometimes oblanceolate or oblance-elliptic), 18–100 mm long, 2–12.5 (–20) mm wide, those on the branches that subtend

flowers often 2–4 times smaller than those on the main stem, the apex acute to narrowly acute, margin with remote but pronounced hydathodal glands, very occasionally minutely papillose-serrulate on the upper margin, base narrowly cuneate or narrowly acute, sessile or with petioles up to 3 mm long. Stipules dark brownish purple, triangular-ovate or lanceolate, succulent, 0.2–0.4 mm long, 0.1–0.3 mm wide. Flowers in upper leaf axils, sometimes rather congested and in an inflorescencelike arrangement. Sepals creamy white within, the apex pale green, broadly ovate-deltate and boat-shaped, flaring outward, apex acute or acuminate, 2–4 mm long, 1.6–4 mm wide, margin smooth or minutely papillose-serrulate. Petals 0. Anthers 0.55–0.9 mm long; filaments nearly translucent, 1.1–1.7 mm long, slightly dilated toward the base. Pollen grains shed singly. Nectary disc bright yellow, square with rounded corners, raised 0.5–0.8 mm on top of the ovary, 2–3.3 mm across, prominently 4-lobed, glabrous. Style pale green, 0.8–1.3 mm long, glabrous; stigma light yellowish, subglobose, 0.25–0.75 mm across, shallowly 4-lobed on top. Capsules glabrous, obpyramidal, winged on the corners, 3–5 mm long, 2.8–4.5 mm wide (including both wings), the wings ca. 0.5–0.9 mm broad, smooth or minutely papillose, central portion on each side of the wall often somewhat bulging longitudinally, sessile or with pedicels up to 0.8 mm long. Bracteoles flanking capsule base, lance-elliptic or narrowly so, 2.4–4.7 mm long, 0.6–1.5 mm wide, glabrous, margins minutely papillose or smooth. Seeds light brown, ellipsoid, slightly curved on both ends, 0.6–0.7 mm long, 0.3–0.35 mm wide, the surface cells elongate transversely to the seed length. Self-compatible. Gametic chromosome number, $n = 24$.

Distribution. The habitats of *L. alata* include ditches; shores of ponds and lagoons; peaty or sandy swales; open cypress swamps; sandy borrow pits in open pine woods; swampy, flat outcrops of oolitic rocks; wet savannas; tidal flats; brackish marshes; sandy beach strands; and hammocks. This species occurs along the eastern Coastal Plain from southeastern Virginia through eastern North Carolina, with sporadic populations in eastern South Carolina and Georgia; it reaches its southern limit at localities scattered throughout the Florida peninsula. To the west this species extends along the Gulf Coast through the Florida panhandle into southern Alabama, Mississippi, and extreme eastern Louisiana (Fig. 38). Proctor (1982) reported disjunct populations from Jamaica. Flowering from June to October; fruiting from July to November.

Representative specimens examined. U.S.A. ALABAMA: Baldwin Co., ca. 7 mi. W of Gulf Floors, *Kral 32612* (MO, SMU, VDB). FLORIDA: Bay Co., ca. 10 mi. W-NW of Mexico, *Kral 22985* (VDB). Ludwigia alata has been confused with *L. lanceolata* (Long & Lakela, 1976; Raven & Tai, 1979; Godfrey & Wooten, 1981; Wunderlin, 1982; Clewell, 1985), owing to their similarity in being glabrous, apetalous, and most notably, in having winged, obpyramidal fruits, a character not shared by other species of sect. *Microcarpium*. Raven & Tai (1979) reported the chromosome numbers of *L. alata*. They reported tetraploid counts of $n = 16$ and hexaploid counts of $n = 24$ as a result of not differentiating *L. lanceolata* from *L. alata*. It has now become clear that *L. alata* is a hexaploid and *L. lanceolata* is a tetraploid (Peng, 1988). In my biosystematic study (1988), I reported that reciprocal artificial hybrids between the two species exhibit a modal meiotic configuration of 16 bivalents and 8 univalents, which suggests that they have two genomes in common. Similar results were obtained when the hexaploid *L. alata* was crossed with any of the other tetraploid species of sect. *Microcarpium*. Cytogenetic and morphological data suggest that *L. alata* may have originated following hybridization between the tetraploid *L. lanceolata* and the diploid *L. microcarpa* or populations ancestral to them (Peng, 1988).

Despite their superficial resemblance, *Ludwigia alata* differs sharply from *L. lanceolata* in that the pollen grains are shed singly in *L. alata* and as tetrads in *L. lanceolata* (Praglowski et al., 1983), and the seed surface cells are columnar in *L. alata* vs. suborbicular in *L. lanceolata*. Other characters used by monographers to differentiate the two species include seed shape (ovoid in *L. alata* vs. cylindric in *L. lanceolata*) and sepal shape and size (slightly longer in length than width and nearly as long as the capsule in *L. alata* vs. about as long as wide, shorter than the capsule in *L. lanceolata*) (Small, 1933; Munz, 1944, 1965). These characters, however, are not always clear and reliable.

The leaf base is usually decurrent in *Ludwigia alata*, resulting in the winged stem. The wings are up to 1.8 mm wide in extreme cases. In *L. lanceolata*, by contrast, the stems are nearly smooth. However, the character of the winged stem in *L. alata* is too variable to be diagnostic.

Ludwigia alata has, like all other tetraploids of the section, lost its petals in the course of evolution. In a specimen collected from Duval Co., Florida (*Creager 639*, NCU), one vestigial petal is present on a single flower. Progeny of *Peng 4205* collected from Dade Co., Florida, exhibited minute, vestigial petals on some flowers, too, in greenhouse cultivation. Although normally lacking petals, *L. alata* has whitish sepals that flare outward. This character, along with the fact that the distance between the androecium and the gynoecium is such that mechanical self-pollination cannot usually occur, indicates that *L. alata* is an obligate cross-pollinator. By contrast, *L. lanceolata* has greenish, ascending sepals and is modally self-pollinating. *Ludwigia alata* and *L. lanceolata* are compared in Table 5.

Ludwigia alata occurs with *L. curtissii*, *L. linifolia*, *L. microcarpa*, *L. pilosa*, *L. simpsonii*, and *L. suffruticosa*. Natural hybrids between *L. alata* and *L. pilosa*, and between *L. alata* and *L. suffruticosa*, all of which require insect vectors to effect pollination, are abundant. (See Peng [1988] for voucher information of such natural hybrids.) The hybridity of field populations of *L. alata* × *L. pilosa* is initially suggested by the combination of the winged ovaries/capsules and minute, uniform pubescence found in these plants. Of the 15 taxa in sect. *Microcarpium*, only *L. alata* and *L. lanceolata* have winged capsules, and they are glabrous. *Ludwigia pilosa* and *L. ravenii* are consistently pubescent, and *L. sphaerocarpa* is variable in vestiture; none of them has winged capsules. The parentage of the hybrids between *L. alata* ($n = 24$) and *L. pilosa* ($n = 16$) is further verified by (1) their reduced level of stainable pollen (ca. 45–70%, which is indicative of a heteroploid cross), and (2) a mixture of columnar and isodiametric cells and some other irregular cells on their seed surface (among the pubescent putative parental species, only *L. pilosa* differs significantly in the seed surface pattern from *L. alata*).

Natural hybrids between *Ludwigia suffruticosa* ($n = 16$) and *L. alata* ($n = 24$) are difficult to recognize in the field. They are very similar to *L. alata* in general aspect, having winged capsules and slightly winged stems, as well as pollen grains shed singly. However, they differ from *L. alata* in that their stems are less branched; their flowers are borne only in the upper leaf axils of each

branch; their capsules are smaller, presumably as a result of reduced seed set; and their seed surface consists of a mixture of many columnar but relatively shorter cells, as well as somewhat isodiametric cells (typical of *L. suffruticosa*), and is irregular.

9. Ludwigia sphaerocarpa Elliott, Sketch Bot. S. C. & Ga. 1: 213. 1817. *Isnardia sphaerocarpa* (Elliott) DC., Prodr. 3: 61. 1828. *Ludwigia sphaerocarpa* Elliott var. *typica* Fern. & Griscom, Rhodora 37: 174. 1935. TYPE: U.S.A. South Carolina: Orangeburg Co., in swampy grounds near Orangeburg, flowers in August, s.d., *S. Elliott s.n.* (holotype, CHARL; photographs, GH, MO; possible isotype, PH). Figure 51.

Ludwigia sphaerocarpa Elliott var. *deamii* Fern. & Griscom, Rhodora 37: 174. 1935. TYPE: U.S.A. Indiana: Porter Co., low border of Lake Walker, NW of Baileytown, 23 Aug., 1925, *C. C. Deam 42350* (holotype, GH).

Ludwigia sphaerocarpa Elliott var. *jungens* Fern. & Griscom, Rhodora 37: 174. 1935. TYPE: U.S.A. Virginia: Princess Anne Co., Cape Henry, pool in sandy barrens, 23 Sep., 1933, *M. L. Fernald & L. Griscom 2862* (holotype, GH).

Ludwigia sphaerocarpa Eliott var. *macrocarpa* Fern. & Griscom, Rhodora 37: 174. 1935. TYPE: U.S.A. Massachusetts: Plymouth Co., Lakeville, stony shore of Quitacas Pond, 27 Aug., 1899, *W. P. Rich s.n.* (holotype, GH).

Stems erect, well-branched, (40–)60–110 cm tall, glabrous to densely strigillose; aerenchyma often very prominent in the lower part. Stolons many, up to 90 cm long, 2–3.5 mm thick, floating, sometimes branched, the leaves purplish, narrowly elliptic or oblanceolate, sometimes spatulate, 9–30 mm long, 4–8(–13) mm wide, glabrous to densely strigillose, apex acute or obtuse, margin with distinct hydathodal teeth or sometimes subentire, base attenuate into ± winged petiole 1.5–3 mm long. Cauline leaves narrowly elliptic or lanceolate to sublinear or linear, those on the main stem (26–)60–100 mm long, 4.5–11(–16) mm wide, those of the branch 20–50(–60) mm long, 2.5–5(–6) mm wide, glabrous to densely strigillose, apex acute to very narrowly acute, margin entire, hydathodal glands often visible in main cauline leaves, base attenuate or narrowly cuneate into petioles 1–4(–10) mm long. Stipules reddish purple, lanceolate or deltoid, 0.15–0.4 mm long, 0.1–0.2 mm wide. Flowers in upper leaf axils, lax to very crowded on branches. Sepals green without, yellow within, ovate-deltoid, ascending, 2–3.5(–4) mm long, 1.6–3(–3.3) mm wide, glabrous to densely strigillose on both surfaces, apex acuminate, margin entire. Petals 0. Anthers 0.5–0.8 mm long, filaments yellow, 1–1.7 mm long, slightly dilated toward base. Pollen grains shed as tetrads. Nectary disc bright yellow, raised 0.4–0.6 mm on ovary apex, 1.5–3 mm across, 4-lobed, glabrous to short hirtellous between the lobes. Style yellow, 0.55–1(–1.25) mm long, glabrous to strigillose, especially below. Stigma yellow, subglobose, 0.35–0.5 mm long, 0.4–0.7 mm thick. Capsules sometimes pinkish, subglobose, (1.8–)2–4(–4.5) mm long, 2–4 mm thick, glabrous to densely strigillose, pedicels 0.5–1.2(–2.3) mm long. Bracteoles subopposite on short pedicel, rarely flanking capsule base, linear to very narrowly lanceolate, rarely lanceolate, 0.5–1.5 mm long. Seeds brown to light brown, elliptic, 0.45–0.7 mm long, 0.25–0.35 mm wide, the surface of a mixture of columnar cells, these elongate and transversely elongate to the seed length, sometimes oblique, the orientation of cells often variable from seed to seed. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *L. sphaerocarpa* grow in drainage ditches, on stream or pond shores, and in river marshes, swales, swamp forests, edges of limestone sinks, peaty bogs in pastures, and interdunal marshes. This species has an extensive distribution along the Atlantic coast, ranging from Massachusetts to northcentral Florida. To the west it extends through the panhandle of Florida, southwestern Georgia, southeastern Alabama, central and southwestern Louisiana, and reaches eastern Texas. Disjunct populations occur in southcentral Tennessee, extreme southwestern Indiana, along Lake Michigan in northeastern Illinois and northwestern Indiana, and in westcentral New York (Fig. 52). Flowering from June to September; fruiting from August to November.

Ludwigia sphaerocarpa is highly polymorphic. Its variability is largely the result of its wide geographic (and latitudinal) range, the sporadic, semi-isolated distribution of the populations, the interaction of differential adaptation and genetic drift made possible by its pattern of distribution, and its possible hybrid nature (see below). Hybridization with *L. pilosa* in regions where their ranges overlap apparently provides an important source of variability in *L. sphaerocarpa*.

Populations of this species consist of individuals that vary in overall pubescence, leaf shape and size, fruit size, and density of fruits on branches. Fernald & Griscom (1935) recognized var. *jungens*, var. *macrocarpa*, and var. *deamii* based on various combinations of these characters. In their treatment, the varieties were separated as follows:

Rameal leaves strongly reduced, glabrous or pubescent, lanceolate.
- Mature hypanthium small, 2.5–3.2 mm long, 2.8–4 mm broad, averaging broader than long.
  - Hypanthium pubescent; leaves narrowly lineear-lanceolate and attenuate ..... var. "*typica*" [var. *sphaerocarpa*]
  - Hypanthium, branches, and leaves pubescent; leaves more broadly lanceolate, not attenuate ..... var. *jungens*
- Mature hypanthium larger, 3.5–4.6 mm long, 3.2–4 mm broad, averaging longer than broad ..... var. *macrocarpa*

Rameal leaves scarcely smaller than the primary ones, pubescent, narrowly oblong; stems pubescent; hypanthium pubescent, 3 mm long, about as wide ..... var. *deamii*

In his revisions of the New World species of *Ludwigia*, Munz (1944, 1965) reduced var. *deamii* to synonymy under var. *jungens* and presented the following key to the varieties:

Fruit crowded on branches, 3.5–4.5 mm long, not as wide. Massachusetts to New Jersey ..... var. *macrocarpa*

Fruit not crowded on branches, 2–3.2 mm long, usually wider.
- Main stems and leaves usually glabrous; principal leaves linear-lanceolate and over 7 cm long. Rhode Island to Florida ..... var. *sphaerocarpa*
- Main stems and leaves pubescent to strigose, lanceolate, usually less than 7 cm long. New Jersey to North Carolina, Michigan, and Indiana ..... var. *jungens*

A study of numerous herbarium specimens not available to Fernald & Griscom (1935) and Munz (1944, 1965) has revealed that correlations between these characters are not consistent; they often intergrade. Indeed Munz (1944) noted that "var. *typica* (the typical variety) and var. *jungens* intergrade freely." Under *Ludwigia sphaerocarpa* var. *macrocarpa*, he also wrote, "New Jersey material is sometimes difficult to distinguish from var. *typica* (the typical variety)." In my opinion, it is best to treat *L. sphaerocarpa* as representing an assemblage of variable populations without recognizing the infraspecific taxa. These populations share the following diagnostic characters: subglobose capsules, diminutive bracteoles (shorter than 1.5 mm long), and ovate-deltoid, yellowish, conspicuous sepals.

It is also of interest to note that, although the seed surface cell pattern is generally very regular within populations of members of *Ludwigia* sect. *Microcarpium* (Figs. 19–28, 30–34), this is not the case for *L. sphaerocarpa* (Fig. 29). The seed surface is arranged in columnar cells both transversely elongate and parallel to the seed length, the former alignment often predominating in the central part of the seeds. Seeds with variously oriented surface cells are also seen in some populations. Comparison of the seed surface pattern in populations of *L. sphaerocarpa* with that of various artificial hybrids strongly suggests that earlier hybridizations within the interfertile tetraploid group of sect. *Microcarpium* may have resulted in this widespread series of populations that are more or less stabilized in some of their characteristics, and such hybridizations may still be contributing to the variability of this series of populations.

The biosystematic study of *Ludwigia* sect. *Microcarpium* (Peng, 1988) demonstrated that hybrids between species that differ in their seed surface cell pattern always show a mixture of cell types or cells of intermediate shapes and sometimes of randomly oriented cells. Similarly, hybrids resulting from crossing a densely hirtellous species with a glabrous one always exhibit minutely villous or strigillose pubescence. Of the tetraploid *Ludwigia* taxa that are interfertile with *L. sphaerocarpa*, *L. ravenii* and *L. glandulosa* subsp. *brachycarpa* are the only ones with columnar seed surface cells elongate transversely to the seed length, whereas *L. polycarpa* and *L. glandulosa* subsp. *glandulosa* are the only taxa with columnar seed surface cells elongate parallel to the seed length. Both subspecies of *L. glandulosa*, having narrow, subcylindrical capsules, are unlikely to be parents of *L. sphaerocarpa*. In seed surface pattern and overall pubescence, *L. ravenii* (densely hirtellous) and *L. polycarpa* (glabrous) seem to be suitable parental candidates. However, that they both have oblong-obovoid capsules and are highly autogamous, in contrast to subglobose capsules and outcrossing habit of *L. sphaerocarpa*, renders it unlikely that they have been involved directly in the formation of *L. sphaerocarpa*. One or possibly both parents of *L. sphaerocarpa* are likely extinct.

The morphological variation in *Ludwigia sphaerocarpa* is further complicated by its frequent natural hybridization with *L. pilosa*, which has apparently resulted in many hybrid swarms or introgressed populations. These plants generally exhibit varying degrees of intermediacy in diagnostic characters such as seed surface pattern, overall pubescence, bracteole size, sepal shape and size, and leaf shape. The following specimens show intermediacy in at least two of the above characters or a combination of some of the diagnostic features of *L. pilosa* with some of those of *L. sphaerocarpa*:

U.S.A. ALABAMA: Escambia Co., 2.5 mi. N of Atmore Prison, off Hwy. 21, *Harvey 275* (UNA). FLORIDA: Citrus Co., 5 mi. S of Homosassa, *Kral 7772* (FLAS, GH, NCU, US, USF, VDB). Columbia Co., 2.5 mi. N of Ellisville, along U.S. Hwy. 41, *Raven 18634* (DS). Dade Co., near Lake Okeechobee, *Fredholm 6182* (GH, NY, US). Duval Co., near Jacksonville, *Curtiss 4324* (DS, ND, NY, US), *Curtiss 5214* (GH). Highlands Co., S end of Lake Istokpoga, *Raven 18683* (DS, NCU); E of Sebring, Carter Creek Swamp, 1948, *Garrett s.n.* (FLAS); 2 mi. S of Parker Islands, *Brass 15325* (US). Hillsborough Co., River State Park, along U.S. Hwy. 301, 1978, *Rochow & Lopez s.n.* (USF); 1 mi. N of bridge on Tarpon Springs–Lake Fern Road, *Poppleton 699* (DS). Lake Co., in the vicinity of Eustis, *Nash 1041* (F, GH, MO, MSC, NY, PH, S, US). Madison Co., 6.8 mi. W of Greenville, along U.S. Hwy. 90, *Raven 18629* (DS); 10 mi. S of Greenville, *Kral 3769a* (FSU, GA, GH, NY, SMU, TENN, UNA, USF). Manatee Co., NE of intersection of state roads 62 & 39, *Shuey 1712* (USF). Polk Co., ca. 3.3 mi. SW of Polk City, along FL Hwy. 33, *Smith & Myint 586* (FLAS, FSU, NCU). St. Johns Co., St. Augustine, 1875, *Reynolds s.n.* (F, FLAS, MO, NY—2 sheets, PH); 1876, *Garber s.n.* (FLAS). Wakulla Co., vicinity of Panacea, *Godfrey 60276* (FSU). GEORGIA: Colquitt Co., 8 mi. NE of Moultrie, *Kral 15008* (VDB). Emanuel Co., 0.8 mi. S of Interstate 16 on U.S. Hwy. 1, *Peng et al. 4025* (MO), *Peng et al. 4026a* (MO). Richmond Co., Augusta, Sanitary Dairy Pond, 1924, *Hildebrand s.n.* (DUKE). Wilcox Co., 10.9 mi. NNW of Abbeville, *Hardin & Dunkan 14246* (GA). NORTH CAROLINA: Robeson Co., ca. 1.5 mi. S of Luberton, *Kral 19030* (VDB, mixed with *L. pilosa*). SOUTH CAROLINA: Aiken Co., 1869, *s.c., s.n.* (US); Beaufort Co., St. Helena Island, 1884, *Cuthbert s.n.* (FLAS). Colleton Co., 4.2 mi. E of Smoaks, *Raven 18718* (DS, 2 sheets, NCU). TEXAS: Freestone Co., 5 mi. SE of Dew, on Hwy. 75, *Correll 35249* (LL); 15 mi. SE of Fairfield, *Kral 111* (FSU). Gonzales Co., Ottine, 1936, *Tharp s.n.* (MO, SMU, TEX). Harris Co., Gosby, 1923, *Fischer s.n.* (S, US); Humble, *Tharp 4518* (MO); Sheldon, *Reverchon 2301* (MO). Hardin Co., 1937, *Tharp s.n.* (TEX). Nacogdoches Co., Nacogdoches, *Waller 273* (SMU, TAES). Orange Co., 1.7 mi. N of Mauriceville, *Shinners 25116* (SMU). Wood Co., 2 mi. N of Mineola, *Correll 35021* (LL); Lake Ellis, *Lundell & Lundell 11748* (LL, SMU).

Some of the above putative hybrid populations are from central and southern Florida, where neither typical *Ludwigia pilosa* nor *L. sphaerocarpa* occur (Peng, 1988, fig. 22). This suggests that their physiological characteristics, and thus their ecological tolerances, may differ from those of the parents in such a way as to allow them to occur in novel habitats and areas where neither of their parents can survive.

The following collections are unusual in being densely hirtellous (having erect hairs ca. 0.4–0.8

mm long), but they are otherwise typical of *Ludwigia sphaerocarpa*. They may represent introgressants between *L. sphaerocarpa* and either *L. pilosa* or *L. ravenii*.

U.S.A. FLORIDA: Flagler Co., vicinity of Andalusia, *Godfrey & Reinert 61149a* (FSU). SOUTH CAROLINA: Beaufort Co., 0.8 mi S of Yemassee on Co. Rd. 3, *Bell 4703* (NCU); *Raven 18716* (DS, FLAS, TEX). Hampton Co., 0.8 mi. NNW of Shirley on Co. Rd. 20, *Bell & Ahles 18254* (NCU). Jasper Co., 5 mi. S of Ridgeland, on U.S. Hwy. 17, *Dille & Dille 346* (MO); 7 mi. N of Hardeeville, on U.S. Hwy. 17, *Dille & Dille 349* (MO). TEXAS: Angelina Co., N of Boykin Springs, Angelina National Forest, *Correll 34910* (LL). Hardin Co., between Silsbee and Kountze, S of Hwy. 418, SW of county dump grounds, *Amerson & Watson 228* (LL). Harris Co., Humble, *Tharp 4518* (US). Montgomery Co., 12 mi. W of Cleveland, *Kral 21041* (DS, VDB—2 sheets).

Plants of the following collections were found to have one to three vestigial, yellow petals in some of the flowers:

U.S.A. FLORIDA: Flagler Co., near Korona, 1944, *Butts s.n.* (GH). Wakulla Co., on U.S. 98, 5 mi. W of FL 59, *Dille & Dille 401* (MO). NEW YORK: Suffolk Co., Long Pond, Sag Harbor, *Muenscher & Curtis 6357* (NY).

Judged by their morphology as well as their full seed set, these plants are more likely to be mutants showing an ancestral trait rather than hybrids between *Ludwigia sphaerocarpa* and one of the petaliferous species of sect. *Microcarpium*.

Almost all populations of *Ludwigia sphaerocarpa* are at least sparingly strigillose, especially on the ovary/capsule walls. The following two glabrous collections from Louisiana are exceptional:

U.S.A. LOUISIANA: Cameron Parish, in "The Pool," Lacassine Wildlife Refuge, *Thieret 16410* (DUKE, GA, MO, SMU). Rapides Parish, Red River, 1840, *Hale s.n.* (US).

They seem to parallel the glabrous variants of *Ludwigia linearis* (see above) in which a few glabrous plants may grow intermixed locally with densely strigillose individuals.

Ludwigia sphaerocarpa is one of the few species in sect. *Microcarpium* in which the distance between the androecium and the gynoecium is such that self-pollination is impossible without the intervention of pollen vectors. Although the flowers of *L. sphaerocarpa* are apetalous, their sepals are adaxially yellowish. This, along with the bright yellow nectary disc, which produces copious nectar, attracts many insects to the flowers of this apparently largely outcrossing species.

In the field, *Ludwigia sphaerocarpa* grows with *L. glandulosa*, *L. linearis*, *L. microcarpa*, *L. pilosa*, and *L. polycarpa* and hybridizes with all but the small-flowered, modally selfing *L. microcarpa*. The natural hybrids generally exhibit intermediate morphology, most notably in fruit shape and size, bracteole length, overall pubescence, and seed surface cell pattern. The fruits are plump and contain abundant seeds in homoploid (tetraploid) hybrids. In the heteroploid (triploid) *L. sphaerocarpa* ($n = 16$) × *L. linearis* ($n = 8$), one to four petals were present in most flowers, and seed set was negligible.

In the experimental greenhouse, artificial hybrids have been synthesized between *Ludwigia sphaerocarpa* and the diploid *L. linearis*, *L. microcarpa*, the tetraploid *L. glandulosa*, *L. polycarpa*, *L. suffruticosa*, *L. lanceolata*, *L. pilosa*, the hexaploid *L. alata*, and the octoploid *L. curtissii* (Peng, 1988).

10. Ludwigia pilosa Walter, Fl. Carol. 89. 1788. *Isnardia pilosa* (Walter) Kuntze, Rev. Gen. Pl. 1: 251. 1891. TYPE: U.S.A., "the Carolinas," s.d., *T. Walter 658* (holotype, BM, Walter Herbarium p. 66; photograph, MO). Figure 53.

Ludwigia rudis Walter, Fl. Carol. 89. 1788. TYPE: U.S.A. "the Carolinas," s.d., *T. Walter s.n.* (type not found at BM, Walter Herbarium; possible isotype, P ("No. 3"); photograph, MO).

Ludwigia hirsuta Lam., Encycl. 3: 614. 1792. TYPE: U.S.A. South Carolina: 1785–1792, *J. Fraser s.n.* (holotype, P; photographs, GH, MO).

Ludwigia mollis Michaux, Fl. Bor.-Am. 1: 90. 1803. *Isnardia mollis* (Michaux) Poiret in Lam., Encycl. Suppl. 3: 188. 1813. TYPE: U.S.A. South Carolina: wet places, 1785–1796, *A. Michaux s.n.* (holotype, P; photographs, GH, MO; possible isotype, PH).

Plants hirtellous throughout. Stems much branched, 40–120 cm tall, often with prominent aerenchyma below when submerged in water, the hairs 0.25–0.95 mm long, translucent or spotted with light brown pigments. Stolons up to 2.5 m long, creeping in mud or floating in water, occasionally bearing flowers and fruits, the leaves obovate or elliptic to orbicular, 6.5–20 mm long, 5–11 mm wide, densely hirtellous to nearly glabrous, margin with distinct hydathodal teeth, petioles 2–7 mm long. Cauline leaves (upon drying) usually brownish green adaxially, brown abaxially, elliptic or lance-elliptic to very narrowly so, 15–80(–100) mm long, 3–12(–14) mm wide, those on the main stem usually 1.5–4 times longer than those on the branches, the veins reddish, the hairs 0.3–0.5 mm long, apex acute or narrowly acute, margin entire, hydathodal glands obscure, base acute to narrowly acute or attenuate, sessile or with petioles up to 2(–10) mm long. Stipules brownish purple, ovate to lanceolate, 0.2–0.25 mm long, up to 1 mm

FIGURE 53. *Ludwigia pilosa* (South Carolina: Berkeley Co., *Peng 4397*, MO).—a. Habit, erect stem.—a′. Basal stolons.—b. Cauline leaf.—b′. Stolon leaf.—c. Flowering branch.—d. Flower bud.—e. Flower.—f. Flower, partly dissected to show stigma, style, and disc.—g. Sepal.—h, h′. Adaxial and abaxial views of stamen.—i. Fruit.—j. Cross section of capsule.

wide, usually obscured by hairs on the stem. Flowers usually congested in upper leaf axils. Sepals very conspicuous, creamy white within, usually also tinged with pink along the main veins and edges, occasionally reddish when grown in exposed sites, ovate-triangular or triangular, with 3 parallel main veins that are usually raised and prominent on the adaxial surface, apex elongate acuminate to subcuspidate, ascending with reflexed tips, 3.5–5.5 (–6) mm long, 2–4 mm wide, densely hirtellous within. Petals 0. Anthers 0.6–0.9(–1.3) mm long; filaments yellowish, 1.5–2.5 mm long, distinctly dilated below. Pollen grains shed as tetrads. Nectary disc bright yellow, turning black upon drying, raised 0.3–0.75 mm on top of the ovary, 2–3.8 mm across, indistinctly 4-lobed, densely hirtellous around the style base and often sparsely hirtellous between the lobes. Style 1–2 mm long, sparsely to densely hirtellous, especially below; stigma 0.3–0.6 mm thick. Capsules subglobose or sometimes oblong-obovoid with rounded corners, 3–5 mm long and 3–4.5 mm thick, densely hirtellous, sessile or with pedicels up to 1 mm long. Bracteoles flanking the capsules, attached 1–2.25 mm above capsule base, linear-lanceolate or narrowly elliptic, hirtellous, 3–6.5(–7.2) mm long, 0.25–1.5(–1.7) mm wide. Seeds brown, elliptic oblong or oblong ovoid, slightly curved on both ends, 0.5–0.7 mm long, 0.25–0.35 mm thick, the surface cells nearly isodiametric. Self-compatible. Gametic chromosome number, $n = 16$.

Distribution. Plants of *Ludwigia pilosa* are frequently found in roadside ditches, in river marshes, in swales in sandy pine flats, at edges of pocosins, in peaty bogs, in low grassy savannahs, and in swamp forests. This species is distributed along the Atlantic coast of extreme southeastern Virginia, eastern and central North and South Carolina, southern Georgia, and northern Florida. It extends westward through the Florida panhandle, southern Alabama, Mississippi, and Louisiana, reaching eastern Texas. A disjunct population occurs in northern Alabama (Fig. 54). Flowering from late June through September; fruiting from late July through November.

Representative specimens examined. U.S.A. ALABAMA: Baldwin Co., Fort Morgan Peninsula, *Demaree 35917* (FSU, GH, SMU, USF, VDB). Barbour Co., ca. 5 mi. Ludwigia pilosa is a distinctive species in sect. *Microcarpium* characterized by being densely hirtellous throughout; reddish brown leaf midveins especially abaxially; sepals elongate-triangular, creamy, and often tinged with pink, reflexed at the tips; and capsules subglobose to somewhat oblong-obovoid, with a pair of long bracteoles attached slightly above the base. The only species that has consistently been confused with *L. pilosa* is the recently named *L. ravenii* (Peng, 1984). The similarity in these two species is in aspect and in the vestiture. They differ in many other characters, notably floral parts and breeding systems. *Ludwigia ravenii* is modally autogamous, with obscure greenish sepals, and all of its floral parts are significantly smaller than those of *L. pilosa*. Further, the seed surface cells are transversely elongate rather than subisodiametric.

The flowers of *Ludwigia pilosa*, in contrast, are unable to undergo mechanical self-pollination. Their showy sepals and copious nectar, which is produced by the nectary disc, unfailingly attract various insect visitors such as ants, wasps, bumblebees, honeybees, and moths to effect pollination. *Ludwigia pilosa* grows with diploid *L. linifolia*, *L. microcarpa*, tetraploid *L. glandulosa*, *L. lanceolata*, *L. ravenii*, *L. sphaerocarpa*, *L. suffruticosa*, and the hexaploid *L. alata*, which is closely allied to the tetraploid species group. It forms fertile hybrids with probably all tetraploid species and with *L. alata* when they grow together. Natural hybrids between *L. pilosa* and *L. ravenii* are presumably rare (*L. ravenii* is rare itself) and difficult to detect. An intersectional hybrid between *L. pilosa* and *L. arcuata* ($n = 16$; sect. *Dantia*) was found in Mobile Co., Alabama (Peng, 1988). All natural hybrids are intermediate morphologically, having vestiture similar to that of *L. pilosa* but shorter and other

features diagnostic of the other putative parents (e.g., the winged fruits of *L. lanceolata*, elongate capsules of *L. glandulosa*, and additional features). Two such hybrids have previously been named: *L. capitata β pubens* Torrey & A. Gray (= *L. pilosa* × *L. suffruticosa*) and *L. simulata* Small (= *L. pilosa* × *L. lanceolata*). Kral (1976) reported a range extension of *L. polycarpa* to Alabama, based, in fact, on a natural hybrid population of *L. pilosa* × *L. glandulosa*. The only species that hybridizes extensively with *L. pilosa* and produces many hybrid swarms or introgressed populations is *L. sphaerocarpa*. Plants of these populations exhibit a varying degree of intermediacy between the two species. They are discussed further under *L. sphaerocarpa*.

Hybrids between *Ludwigia pilosa* and the other tetraploid species or the hexaploid *L. alata* are readily synthesized in the experimental greenhouse and are quite fertile. It is generally difficult to obtain hybrids between *L. pilosa* and diploid species or the *L. curtissii* complex. Floriferous and vigorous hybrids of *L. pilosa* × *L. linifolia* and *L. pilosa* × *L. curtissii*, however, were obtained. Seed set was nonexistent or negligible in these hybrids.

11. Ludwigia ravenii Peng, Syst. Bot. 9: 129. 1984. TYPE: U.S.A. South Carolina: Berkeley Co., 0.1–0.2 mi. SW of jct. of Co. 16 and Co. 6, on Co. 16 W of Moncks Corner, scattered in roadside sedgy, sandy ditch, on loam densely covered by *Sphagnum subsecundatum* Nees, associated with *Cyperus, Xyris, Eriocaulon, Paspalum, Panicum, Hypericum, Polygonum, Rhexia, Liatris, Eupatorium, Ludwigia linearis* Walter, *L. hirtella* Raf., 9 Sep. 1982, *Ching-I Peng 4402* (holotype, MO-3041593; isotypes, B, BM, DAO, DUKE, F, FLAS, FSU, FTG, GA, GH, HAST, KYO, LE, MISS, MISSA, MO, NCSC, NCU, NY, P, PE, TAI, TAIF, TENN, TI, US, USF, VDB). Figure 55.

Plants densely hirtellous throughout. Stems erect, usually well branched and leafy, (15–)35–90 cm tall, densely hirtellous, the hairs 0.3–0.6(–0.75) mm long; aerenchyma (if any) slightly developed, in lower stems. Stolons slender, several from the base, to 18 cm long, 0.6–1.5 mm thick, glabrous or hirtellous, occasionally bearing flowers and fruits, the leaves purplish, elliptic to rotund, 10–18 mm long, 6–14 mm wide, apex rotund to acute, base attenuate into a petiole 1–3 mm long. Cauline leaves pale green on both surfaces, narrowly lance-elliptic, 13–65 mm long, 4–15 mm wide, densely hirtellous on both surfaces, the hairs 0.2–0.5 mm long, apex acute, margin entire with minute hydathodal glands, base attenuate into narrowly winged petiole 1–8 mm long. Stipules reddish purple, lanceolate to widely deltate, succulent, 0.25–0.45 mm long, 0.15–0.25 mm wide. Flowers many, in leaf axils, not congested. Sepals green on both surfaces, broadly ovate-deltate, 1.5–3 mm long, 1.4–2.1 mm wide, densely hirtellous without, glabrous within, apex acuminate, margin entire. Petals 0. Anthers 0.3–0.35 mm long, 0.4–0.5 mm wide; filaments 0.7–1.1 mm long. Pollen grains shed as tetrads. Nectary disc greenish, raised 0.3–0.4 mm on ovary apex, 1.4–2.5 mm across, 4-lobed, glabrous. Style 0.25–0.5 mm long, glabrous; stigma subglobose, 0.25–0.45 mm across. Mature capsules oblong-obovoid, obconical when young, (3–)4–5(–5.3) mm long, 2–3.5(–4) mm thick, densely hirtellous, pedicels 0.2–0.5 mm long. Bracteoles attached near capsule base, lanceolate or elliptic to very narrowly so, (1.5–)2–4.3 mm long, 0.25–0.9 mm wide, hirtellous. Seeds light brown, elliptic-oblong with slightly curved ends, 0.5–0.7 mm long, 0.25–0.35 mm thick, pluriseriate in each locule, free, the surface cells elongate transversely to the seed length. Self-compatible and modally autogamous. Gametic chromosome number, $n = 16$.

Distribution. *Ludwigia ravenii* occurs in wet, peaty habitats, such as ditches or margins of ponds, bogs, and swamps. It is found as scattered populations in coastal southeastern Virginia, eastern North Carolina, and southeastern South Carolina and with somewhat disjunct populations in northeastern Florida (Fig. 56). Flowering from July to September; fruiting from August to October.

Specimens examined are cited in full in Peng (1984).

This recently discovered species consists of scattered, morphologically very uniform populations. Owing to its densely hirtellous vestiture and relative rareness, it was previously not well understood and was confused with *Ludwigia pilosa*, the only other species of sect. *Microcarpium* that is consistently densely hirtellous; that species, however, is widespread and common. As was shown in the table comparing *L. ravenii* with related species (Peng, 1984), *L. ravenii* is very distinct from *L. pilosa*.

Ludwigia ravenii has small inconspicuous flowers with greenish sepals and short stamens and styles. Its anthers are firmly appressed to the stigma shortly after anthesis. These characteristics strongly suggest that it is modally autogamous. This was corroborated by my field study at the type

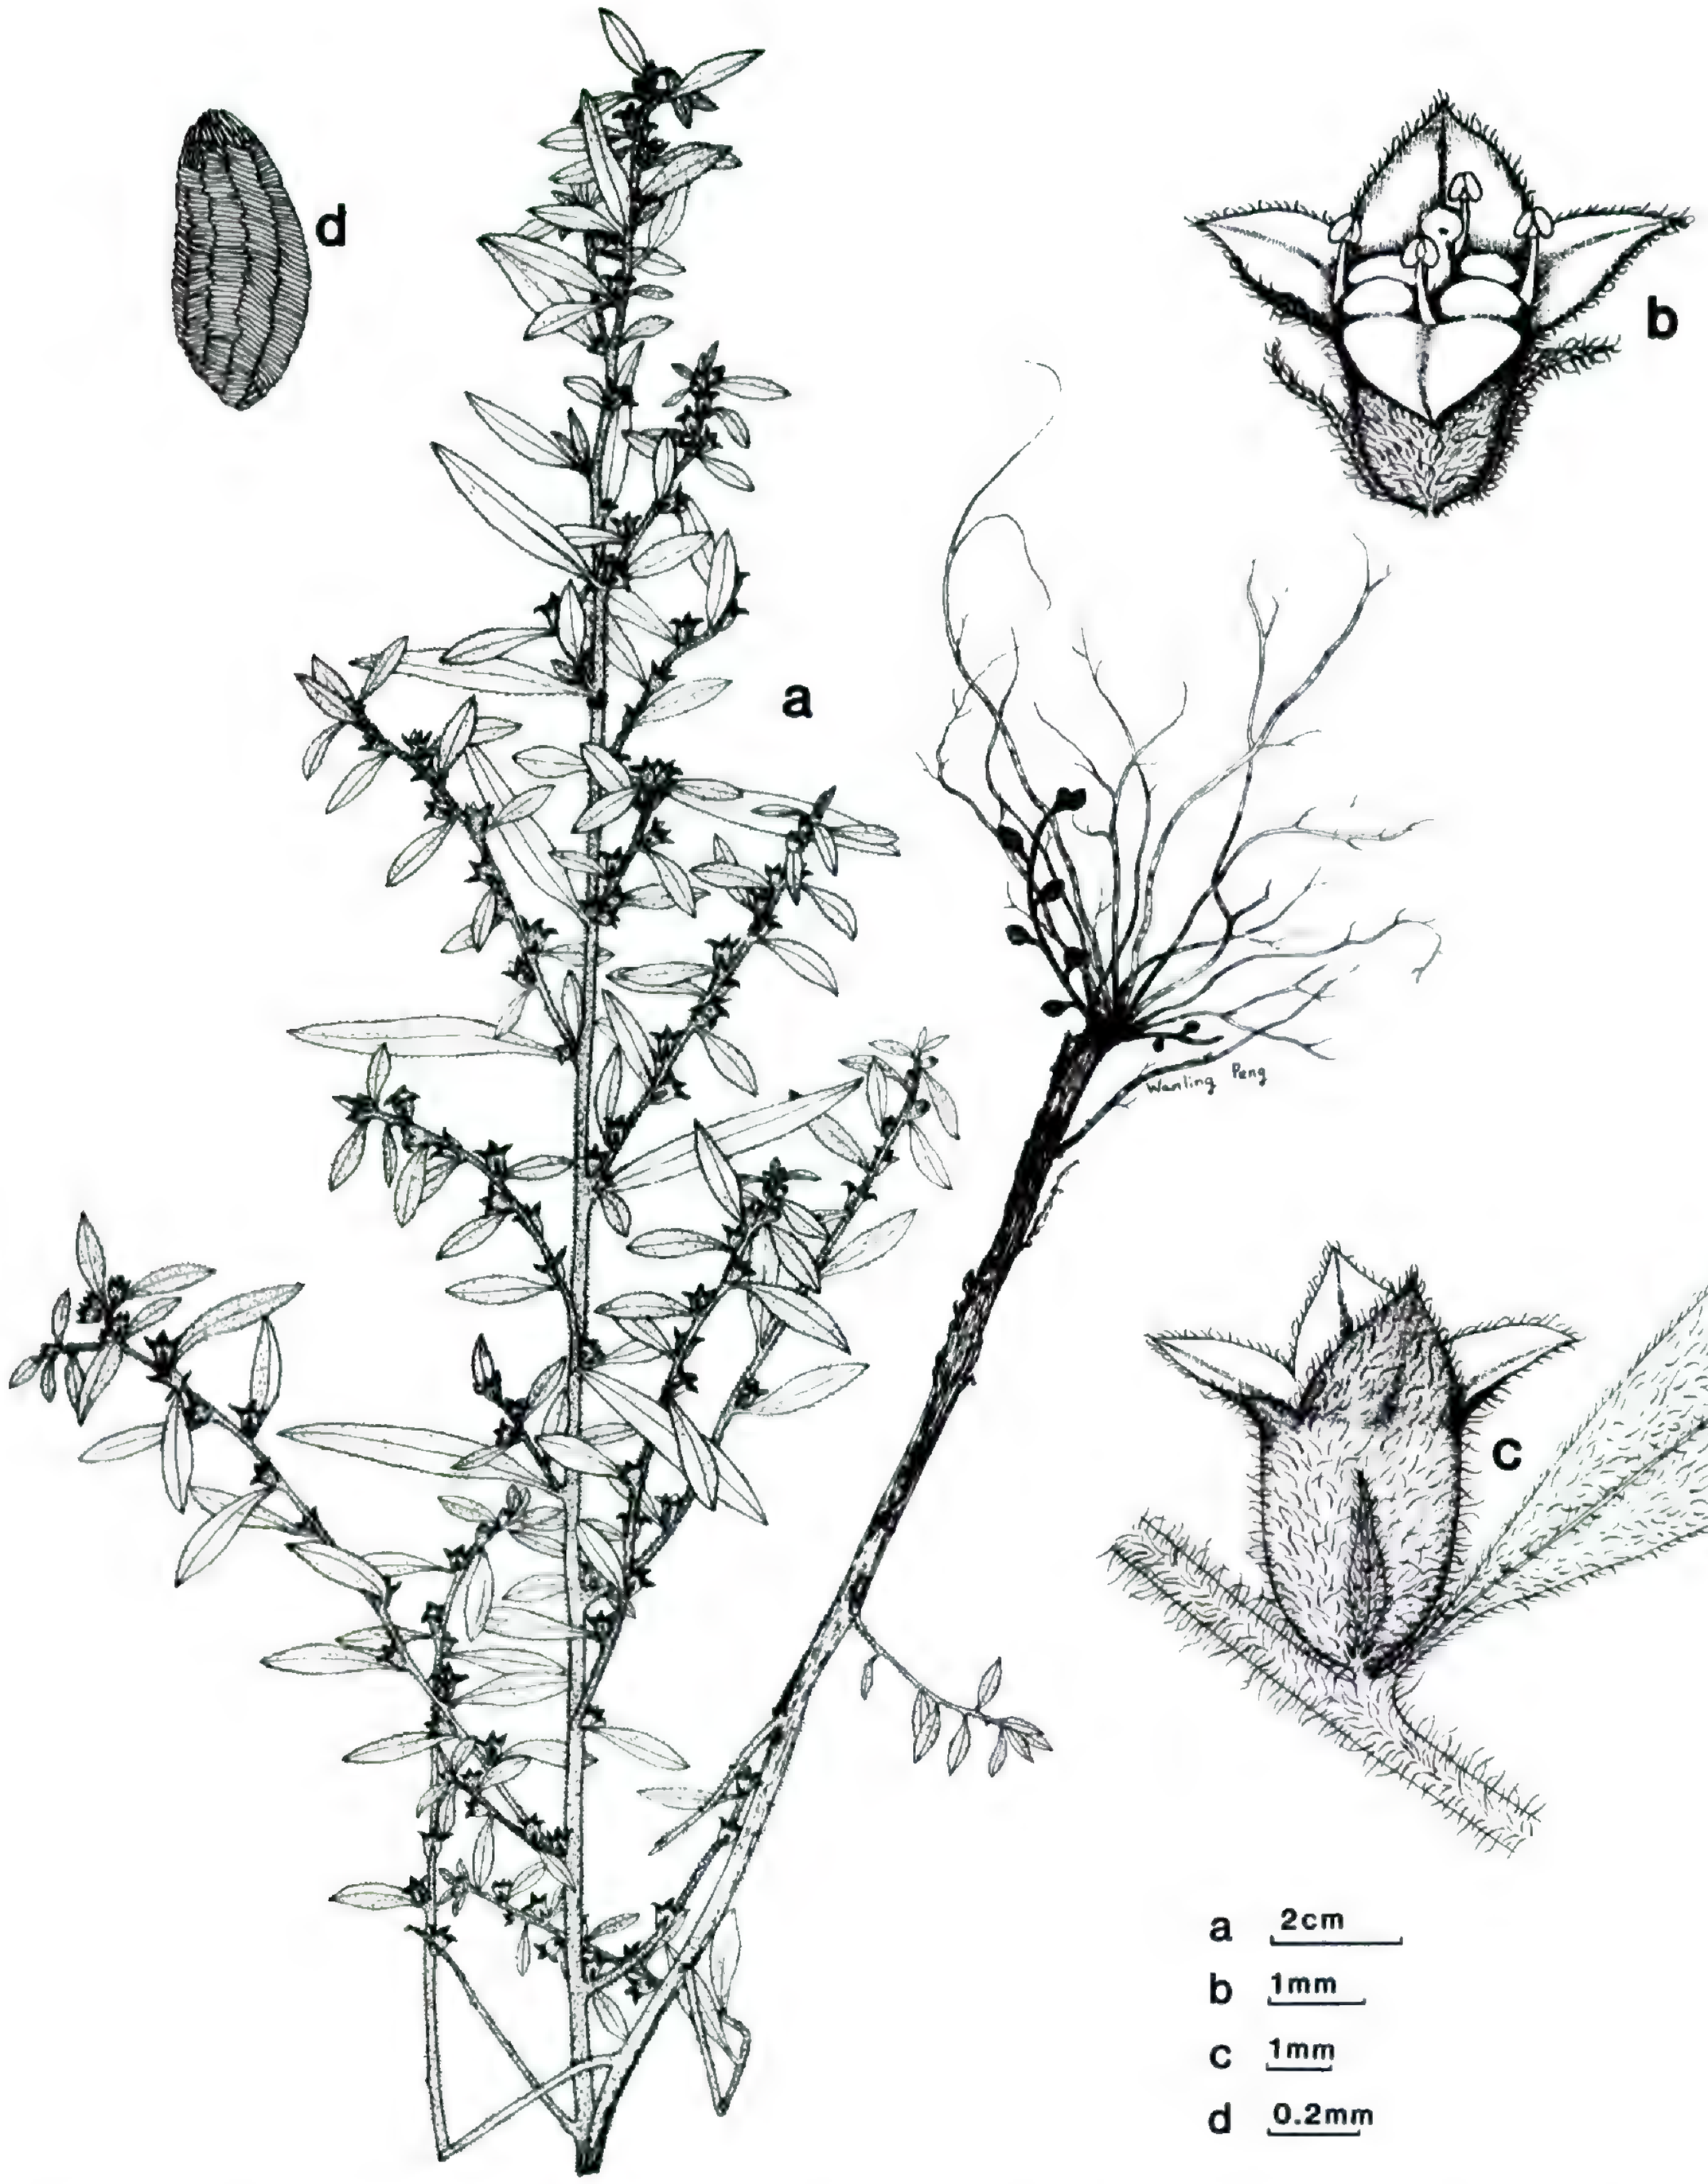

FIGURE 55. *Ludwigia ravenii* (North Carolina, Sampson Co., *Boufford & Wood 18898*, CM).—a. Habit.—b. Flower.—c. Fruit.—d. Seed. (Reprinted with permission from *Systematic Botany*.)

locality (Peng, 1984): for two hours by the ditch where *L. ravenii* grew, I did not observe any insect visitors, whereas 0.5 mi. away in the same ditch, I witnessed a swarm of honeybees visiting and hovering over flowers of a population of *L. pilosa*.

Ludwigia ravenii does not appear to grow aggressively. It starts to form stolons only late in its fruiting season (September to October). Unlike most other tetraploid members of sect. *Microcarpium*, these stolons are usually slender and short, resembling those of *L. microcarpa*. Consequently, the populations consist of scattered individuals instead of large colonies connected by stolons, as is typical in *L. pilosa* and other species.

Live plants of *Ludwigia ravenii* were not collected until after the completion of my biosystematic study of *Ludwigia* sect. *Microcarpium*, so its genetic relationships with the other tetraploid

FIGURE 56. Distribution of *Ludwigia ravenii*.

members of the section remain obscure. The extensive crossing data already available for other species clearly demonstrate, however, that pollen stainability and seed set are high in hybrids between any two tetraploid species, no matter how different morphologically they are (Peng, 1988). Circumstantial evidence thus suggests that *L. ravenii* is almost certainly interfertile with other species of the tetraploid group of sect. *Microcarpium*.

12. Ludwigia microcarpa Michaux, Fl. Bor.-Am. 1: 88. 1803. *Isnardia microcarpa* (Michaux) Poiret in Lam., Encycl. Suppl. 3: 188. 1813. LECTOTYPE: U.S.A. South Carolina: Berkeley Co., Goose Creek, wet places, 1785–1796, *A. Michaux s.n.* (lectotype, P; photograph, MO; here selected). Figure 57.

Plants glabrous, varied in habit, ranging from erect, unbranched, slender herbs to being profusely branched with somewhat woody bases. Stems erect or ascending, rarely prostrate and rooting at the nodes, 5–60 cm tall, 0.4–1.5(–4) mm thick, the leaf bases distinctly decurrent, with or without aerenchyma at stem base. Stolons pinkish, several from base, slender, 4–15(–25) cm long, 0.4–0.75 mm thick, the leaves broadly elliptic to suborbicular, 2.2–6.6 mm long, 2.2–5.2 mm wide, petioles 1.5–5 mm long. Cauline leaves obovate-spatulate or oblanceolate, sometimes narrowly oblance-elliptic, 4–17 mm long, 1.5–10 mm wide, glabrous, apex acute or mucronate, margin subentire, with prominent hydathodal glands forming minute teeth, minutely papillose-strigillose, the hairs ca. 0.05 mm long, occasionally smooth, base attenuate into winged petioles 0.5–5 mm long; main veins on each side of the midrib 3–4, obscure adaxially, conspicuous and slightly raised abaxially; branch leaves sometimes remarkably smaller than main cauline leaves. Stipules reddish purple, lanceolate-deltate, succulent, ca. 0.13–0.15 mm long, 0.1–0.13 mm wide. Flowers axillary, usually not crowd-

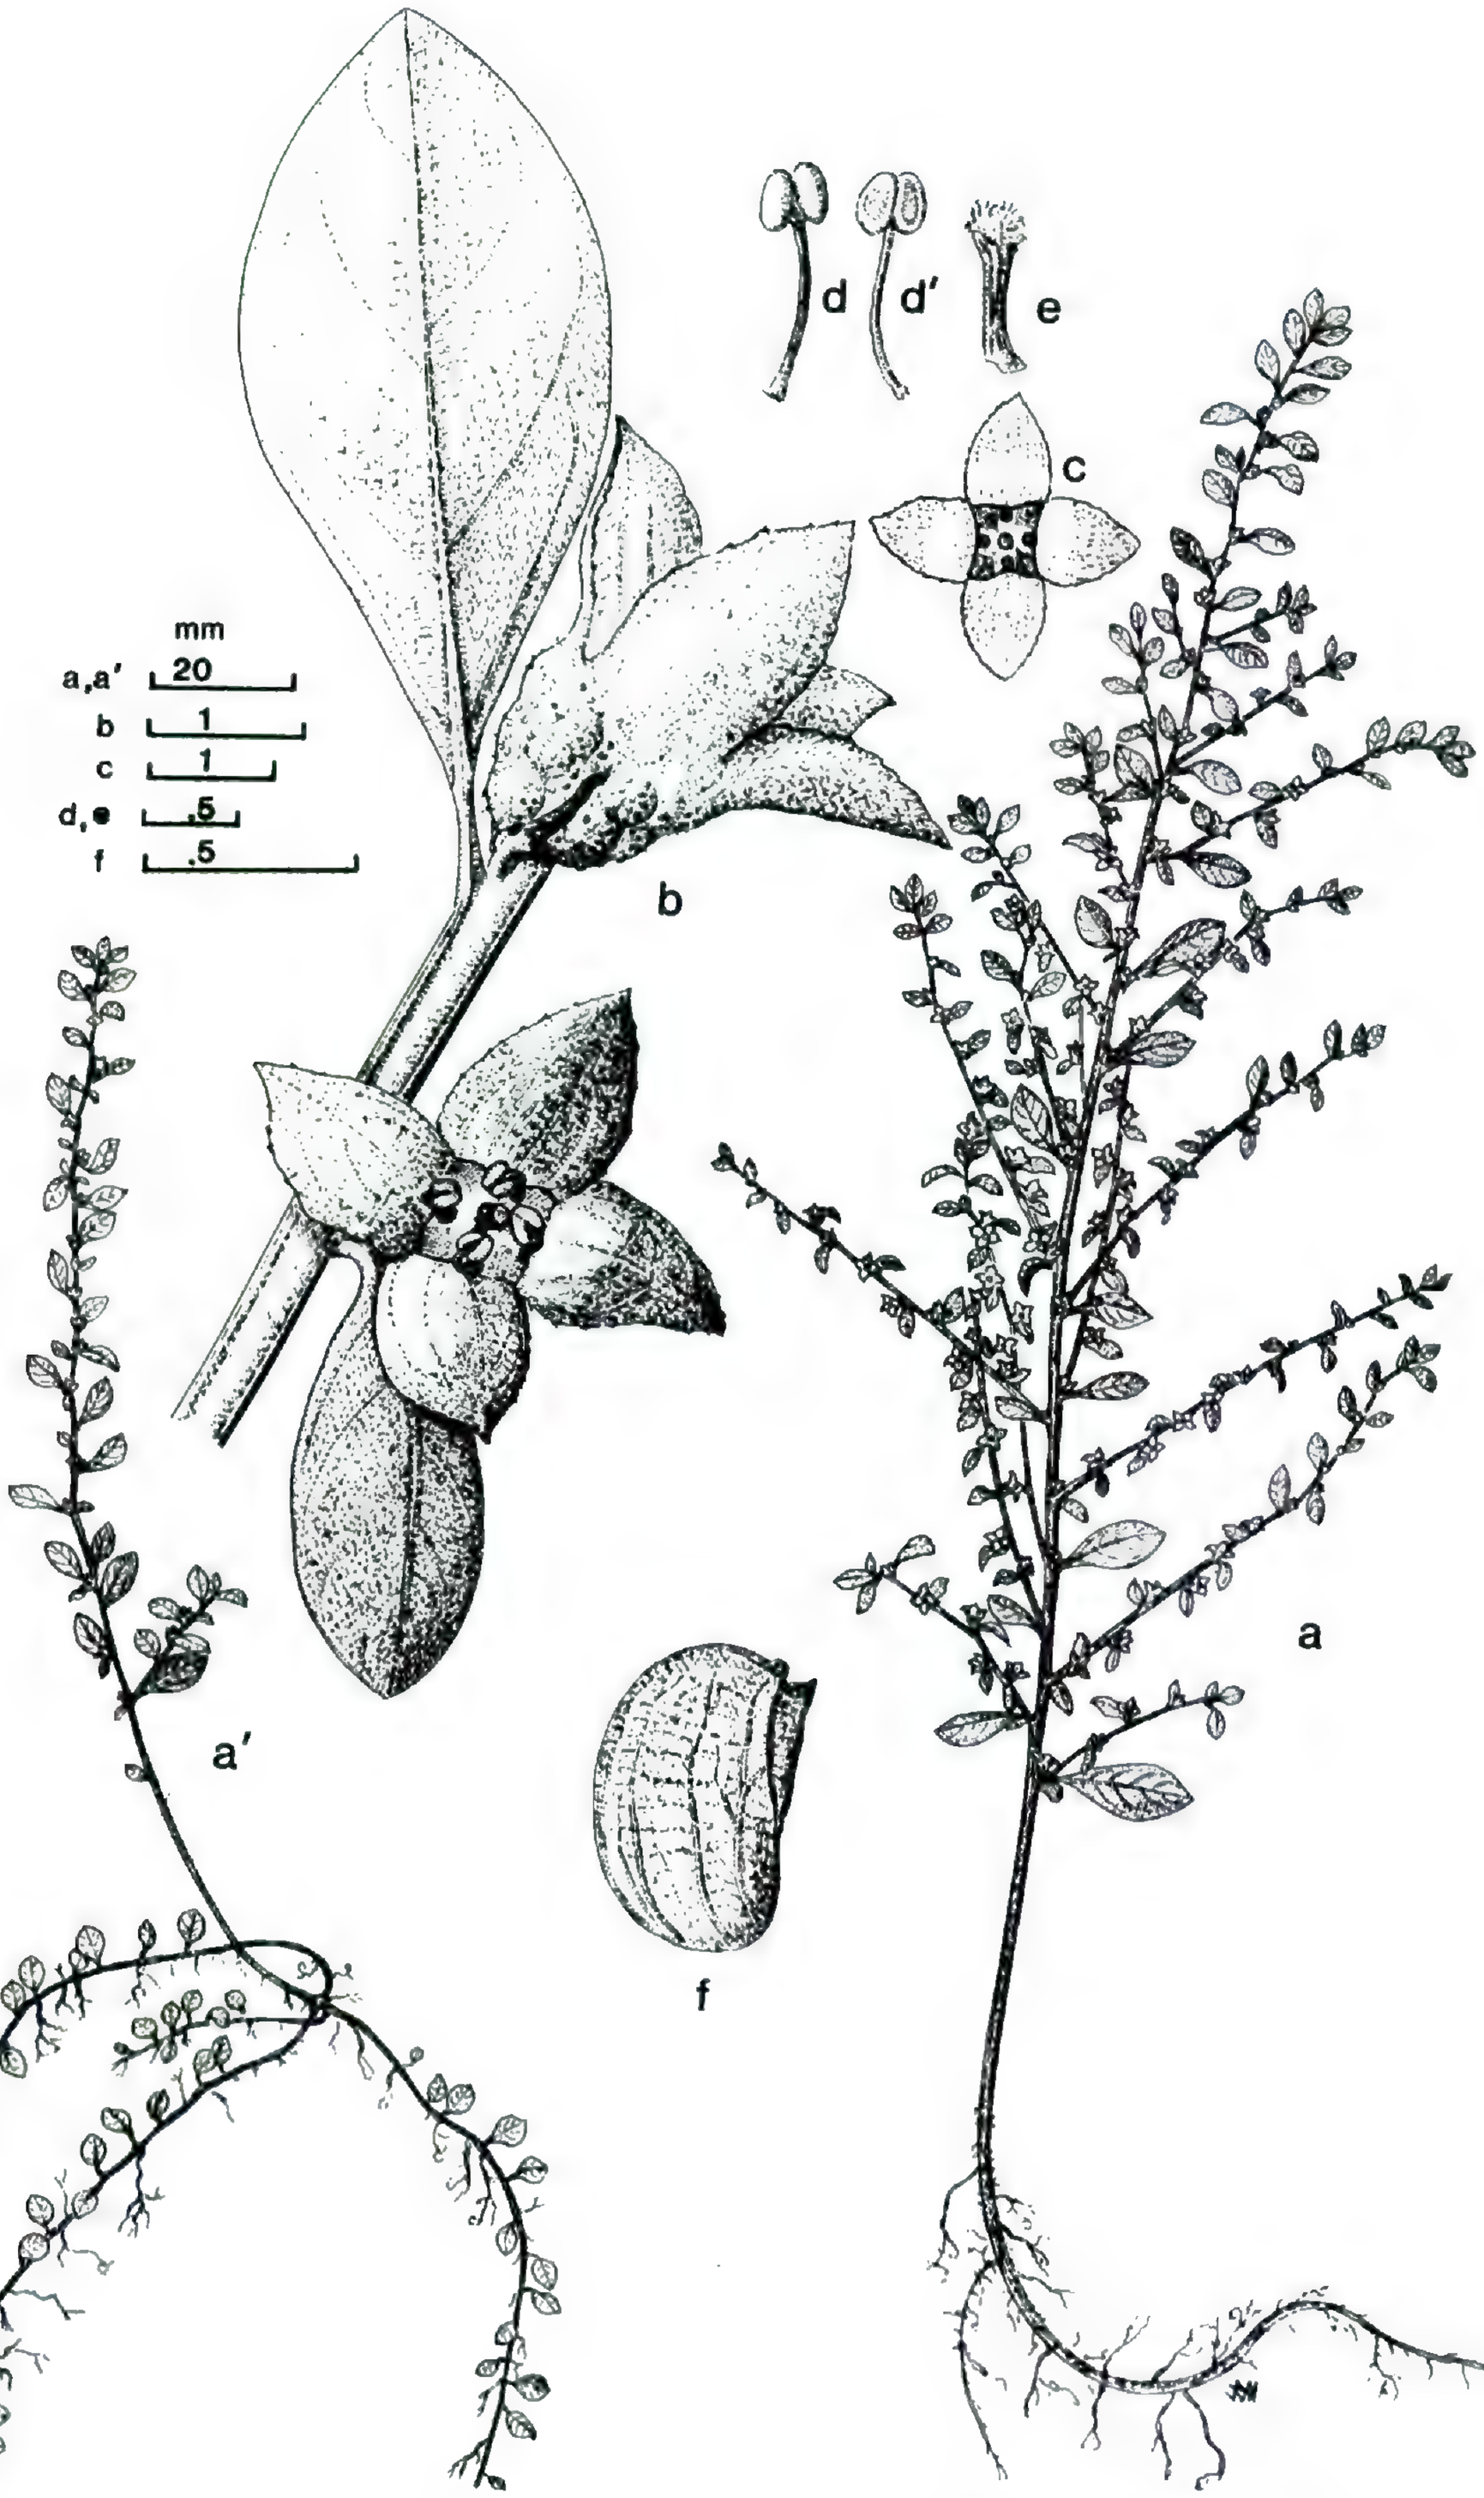

FIGURE 57. *Ludwigia microcarpa*. All but a' from Florida (Monroe Co., *Godfrey 63525*, MO); a' from North Carolina (Brunswick Co., *Leonard & Moore 7579*, MO).—a. Habit, showing erect stem.—a'. Erect plant with basal stolons.—b. Portion of branch with flower and fruit.—c. Top view of fruit.—d, d'. Adaxial and abaxial views of stamen.—e. Stigma and style with pollen on stigma.—f. Seed.

ed. Sepa is green with whitish, thickened base, ascending in flower and spreading in fruit, ovate-deltate, 0.9–2 mm long, 1–1.85 mm wide, glabrous, apex acuminate, margin remotely minutely papillose-strigillose, occasionally smooth. Petals 0. Anthers 0.1–0.2 mm long; filaments translucent, 0.4–0.55 mm long. Pollen grains shed singly. Nectary disc greenish, nearly flat on ovary apex, 0.5–1.2 mm across, 4-lobed, these represented by 4 greenish rhomboid spots, alternating with 4 smaller, rounded reddish scars of anther base on top of the mature capsule, glabrous. Style pale green, 0.25–0.4 mm long, glabrous; stigma green, subglobose, ca. 0.05–0.1 mm thick. Capsules obconical, 1–1.5 mm long, 1.4–1.9 mm thick, minutely puberulent, the hairs ca. 0.05 mm long, thin-walled, containing 6–20 seeds, these sometimes recognizable from outside as bumps, sessile or with pedicels up to 0.15 mm long. Bracteoles flanking capsule base, sublinear or narrowly oblong, 0.35–1.2(–1.5) mm long, 0.1–0.4 mm wide, usually with a swollen base, glabrous. Seeds dark reddish, ovate-oblong, 0.5–0.55 mm long, 0.3–0.4 mm thick, the surface cells transversely elongate, glabrous or sometimes densely covered by strigillose hairs (waxes?). Self-compatible and modally autogamous. Gametic chromosome number, $n = 8$.

Distribution. Plants of *Ludwigia microcarpa* grow in roadside ditches, marshes, ponds and streams at the borders, low meadows, low areas in open woods, edges of swamp forests, brackish marshes, hammocks, and solution pits of limestone on marl prairies. This species occurs along the Atlantic coast of North and South Carolina and Georgia, and throughout the Florida peninsula. It extends westward across the panhandle of Florida, southern Alabama, reaching southern Mississippi, with a single population in southwestern Louisiana. To the north, *L. microcarpa* occurs through western Georgia and central and western Alabama to southcentral Tennessee. Scattered populations are found in northcentral North Carolina and southcentral Missouri (Fig. 58). Furthermore, *L. microcarpa* occurs on several Caribbean islands, including the Bahamas, Cuba, and Jamaica. Flowering and fruiting throughout the year.

Ludwigia microcarpa is the only diploid species of sect. *Microcarpium* that is apetalous and has more or less spatulate leaves. It has the smallest stature, leaves, flowers, and fruits and has the fewest seeds (ca. 10–20) per capsule of any species in the section. Occasionally it may be confused with plants of the "*L. curtissii* complex" (including a hexaploid, *L. simpsonii*, and an octoploid, *L. curtissii*), which have similarly spatulate leaves and turbinate fruits. It is, however, distinguishable from the "*L. curtissii* complex" by its minute capsules (1–1.5 mm long), which are shorter than or subequal to the sepal, its nectary disc of four flat greenish spots, and its reddish seeds. For detailed comparison, see Table 6.

Ludwigia microcarpa is uniform in reproductive structures but variable in vegetative habit. The stems are, as a rule, erect and usually well branched but are sometimes single. The stems and branches are straight or slightly zigzag. In outline, the plants may appear either narrowly oblong or narrowly rhombic when the plants are single or form short, subequal, ascending branches throughout the nodes; or they are triangular or ovate when the branches are gradually shorter from lower nodes up. The stems are normally annual and herbaceous; the plants may perennate either by forming stolons or by sending new shoots up directly from the spent stem base of the previous year. Woodiness is seen in some Florida specimens, presumably as a result of a favorable climate. The following specimen from Leon County, Florida, has an exceptionally woody base about 8 mm thick: sandy alluvium bordering wet woodland, Ochlockonee River, W of Tallahassee, *Godfrey 73131* (MO).

Most plants of *Ludwigia microcarpa* start to flower when young; it is common to find plants 5–10 cm high with flowers/fruits. The apetalous flowers are very small, with a tiny, greenish nectary disc from which a small amount of nectar is produced. Mechanical self-pollination apparently predominates in this species. In the experimental greenhouse, however, it has been successfully crossed to the diploid *L. linifolia* and *L. linearis*, tetraploid *L. glandulosa*, *L. lanceolata*, *L. polycarpa*, *L. sphaerocarpa*, and hexaploid *L. alata* and *L. simpsonii*; these combinations have resulted in the production of vigorous, floriferous hybrids (Peng, 1988). None set any seed. The F_1 hybrids between *L. microcarpa* and other petaliferous dip-

Number/capsule	Ca. 10–20	Ca. 40–80	Ca. 50–150

loids were consistently petaliferous, suggesting that petal formation is controlled by a dominant gene. In other aspects, these F_1 hybrids were intermediate between their parents. Hybrids between *L. microcarpa* and species of higher ploidy level generally resembled the latter but tended to have smaller leaves and flowers.

Ludwigia microcarpa grows with *L. alata*, *L. curtissii*, *L. glandulosa*, *L. linearis*, *L. linifolia*, *L. pilosa*, *L. simpsonii*, and *L. sphaerocarpa*. Natural hybrids have been found between *L. microcarpa* ($n = 8$) and both *L. simpsonii* ($n = 24$) and *L. curtissii* ($n = 32$), both of which resemble *L. microcarpa* morphologically and share a common genome with that species (Peng, 1988). Since *L. simpsonii* and *L. curtissii* differ only in quantitative characteristics, which often overlap, it is impossible to distinguish between *L. microcarpa* × *L. curtissii* and *L. microcarpa* × *L. simpsonii* without knowing the chromosome number, or without seeing the populations in the field. These hybrids are usually readily recognizable by their erect stems; small and oblanceolate to spatulate leaves; apetalous flowers; elevated nectary discs; and minute, obpyramidal ovaries that abort after anthesis. The corners of the ovary/capsule often appear winged to some extent, apparently as a result of the aborted ovaries, which fail to develop into seeds in the locules of such hybrid individuals.

Hybrid populations between *Ludwigia microcarpa* and *L. simpsonii* are apparently common in Florida, where the two species grow in the same

habitats, often intermixed. These plants have a modal meiotic configuration of 8 bivalents and 16 univalents (Peng, 1988).

Confirmed hybrid populations of *Ludwigia microcarpa* × *L. curtissii* were found in Martin Co., Florida, 4.3 mi. E of Okeechobee and Martin county line, on FL 710, at Brady Ranch (*Peng 4202*, MO). Here they occurred along with putative parents by a wide depression between the highway and a railroad. Plants of *L. microcarpa* grew along the swamp border, whereas plants of *L. curtissii* stood in deeper water but were not as abundant as the former. Hybrid plants were scattered between them. The hybrids formed 8 bivalents and 24 univalents at meiosis (Peng, 1988).

Intersectional hybrid populations of *Ludwigia microcarpa* with *L. palustris* (sect. *Dantia*) were found in several counties of North Carolina, Georgia, and Florida (Peng, 1988). Their leaves were small, spatulate to broadly elliptic, alternate, subopposite or opposite; their flowers were small, apetalous, with minute ovaries, and aborting after anthesis; and the stems were prostrate and rooting at the nodes to ascending, suberect, or both. The combination of alternate leaves with a more or less prostrate habit in North American *Ludwigia* is usually indicative of hybridization between plants of sect. *Microcarpium* and sect. *Dantia*.

13. Ludwigia simpsonii Chapman, Fl. South. U.S., 2nd edition, suppl. 2: 685. 1892. TYPE: U.S.A. Florida: Manatee Co., Manatee, low ground, s.d., *C. T. Simpson s.n.* (holotype, US-1384069; isotypes, GH, MO in part, US—2 sheets). Figure 59.

Ludwigia cubensis Helwig, Repert. Sp. Nov. 25: 53. 1928. TYPE: Cuba. Piñar del Río: Remates, Ciénaga La Tumba, wet places, 16 June 1920, *E. L. Ekman 11304* (holotype, B, destroyed; isotypes, S—2 sheets).

Plants glabrous, erect, ascending, decumbent, or often prostrate and rooting at the nodes. Stems 10–60(–75) cm tall, well branched, leaf base slightly decurrent. Stolons rarely seen, new shoots arising from erect stem base or nodes of the trailing main stem, ascending at first, soon erect. Leaves alternate, those on lower nodes often opposite or subopposite, shape varied: spatulate, oblanceolate to very narrowly oblanceolate, or sublinear in extreme cases, 6–15(–20) mm long, (1–)3–7(–11) mm wide, apex acute or mucronate, margin subentire, with hydathodal glands, base attenuate into narrowly winged petioles 2–10 mm long. Stipules reddish purple, narrowly ovate-deltate, succulent, 0.15–0.25 mm long, 0.1–0.15 mm wide. Flowers in leaf axils, rarely congested. Sepals green with whitish, accrescent base, ovate-deltate, ascending, 1.2–1.8 mm long, 1–2 mm wide, apex narrowly acute or acuminate, margin entire. Petals 0. Anthers 0.25–0.35 mm long; filaments nearly translucent, 0.55–0.8 mm long. Pollen grains shed singly. Nectary disc green, raised 0.3–0.35 mm on ovary apex, 0.9–1.3 mm across, distinctly 4-lobed, glabrous. Style greenish, 0.25–0.4 mm long; stigma yellowish, subglobose, 0.15–0.25 mm thick. Capsules obconical, 1.5–2.5 mm long, 1.5–3 mm thick, comprising ca. 30–70(–100) seeds, glabrous or occasionally with minute, puberulent hairs ca. 0.05 mm long, sessile or with pedicels up to 0.4 mm long. Bracteoles attached on opposite sides near the base of capsules, lance-elliptic, 0.9–1.5(–2.5) mm long, 0.35–0.85 mm wide, swollen at base. Seeds light brown or brown, ellipsoid, 0.5–0.6 mm long, 0.3–0.35 mm thick, the surface cells transversely elongate, glabrous, occasionally covered by wax (?) taking the form of minute, appressed or ascending hairs. Self-compatible. Gametic chromosome number, $n = 24$.

Distribution. *Ludwigia simpsonii* occurs in sandy, peaty ditches, open pineland swamps, edges of cypress swamps, tidal flats or nearby marshes, and limestone sinks, sometimes growing as weeds, throughout most of eastern and southern Florida, with somewhat disjunct populations in the eastern part of the Florida panhandle and southernmost Mississippi (Fig. 60). This species also occurs in Cuba and Jamaica. Flowering and fruiting all year.

Representative specimens examined. U.S.A. FLORIDA: Bradford Co., New River, 1896, *Hitchcock s.n.* (F). Brevard Co., North Merritts Island, E side of Rt. 3, N of Wilsons Corner, *Shuey M1391* (USF). Ludwigia simpsonii is very variable in habit and leaf shape. It, *L. curtissii* (including *L. spathulifolia*), and *L. microcarpa* form a closely knit

←

leaves.—b. Leaf.—c. Flower bud.—d. Flower.—d′. Partly dissected flower.—e, e′. Adaxial and abaxial views of stamen.—f. Capsule.—g. Dehiscent capsule.

polyploid complex, with the diploid *L. microcarpa* evidently having played a role in the formation of the other species (Peng, 1988). Its distinctiveness from the diploid *L. microcarpa* is readily perceived in capsule size, shape of nectary disc, seed color, and seed number per capsule. The characters separating *L. simpsonii* and *L. curtissii*, however, are nearly always quantitative and often overlap. Raven & Tai (1979) indicated that the diagnostic characters separating *L. curtissii* and *L. simpsonii*, such as capsule shape and size and leaf shape, are not correlated with chromosome numbers, and that the two species tend to converge in the experimental greenhouse. For reasons of this sort, these two species have frequently been merged under *L. curtissii* in the recent literature (e.g., Long & Lakela, 1976; Raven & Tai, 1979; Godfrey & Wooten, 1981; Wunderlin, 1982). By contrast, basing conclusions on abundant fieldwork and greenhouse and chromosome studies, I (1988) observed that the difference in chromosome number is correlated with mature capsule size. All plants with $n = 24$ have capsules 1.5–2(–2.5) mm long, whereas those with $n = 32$ have mature capsules (2–)2.5–4(–4.7) mm long. The morphology of plants with $n = 24$ fits closely the description of *L. simpsonii*, and the morphology of $n = 32$ plants clearly corresponds to that of *L. curtissii* (including *L. spathulifolia*). Comparison of these two species and the diploid *L. microcarpa* is in Table 6.

Although *Ludwigia simpsonii* and *L. curtissii* frequently are found in the same locality, they appear to be ecologically distinct and seldom occur side by side. *Ludwigia simpsonii* tends to grow along roadsides with other weeds in moist sandy soil. *Ludwigia curtissii* usually grows farther from roadsides, sometimes mixed with tall grasses or sedges, in black muck and often in deep standing water.

Ludwigia simpsonii sometimes grows with *L. alata*, *L. curtissii*, and *L. microcarpa*. Proven natural hybrids are known only of *L. simpsonii* × *L. microcarpa*; they occur in several scattered counties in Florida (Peng, 1988). These hybrids showed a modal meiotic configuration of 8 bivalents and 16 univalents and 4–24% stainable pollen. Their ovaries aborted after anthesis. *Ludwigia simpsonii* may form natural hybrids with *L. curtissii*, but such hybrids would be virtually impossible to pick out without studying their chromosomes and would probably be identified as one of their putative parents. Artificial hybrids between these two closely related species have been synthesized; they produced moderate numbers of seeds and had ca. 80–90% stainable pollen. They consistently showed a meiotic configuration of 24 bivalents and 8 univalents, which indicated that chromosomes of the three genomes in *L. simpsonii* pair with homologues in *L. curtissii*, leaving the eight additional chromosomes in this species unpaired. Based on morphological features and crossing relationships, the octoploid *L. curtissii* was probably derived following hybridization between a petaliferous, narrow-leaved diploid similar to *L. linearis* or *L. linifolia* and the hexaploid *L. simpsonii* (Peng, 1988).

Intersectional hybrids of *Ludwigia simpsonii* and *L. repens* ($n = 24$; sect. *Dantia*) have been found growing intermixed with both putative parents. These plants exhibited few, if any (0–1), associations of chromosomes at meiosis (Peng, 1988), which corroborated an earlier report by Schmidt (1967). The lack of chromosome pairing in hybrids strongly suggests that the three genomes of *L. simpsonii* are distinct from one another and are not homologous with any of the genomes present in *L. repens*. Judged by the fact that *L. simpsonii* often has opposite or subopposite leaves near the base of the stem or at the seedling stage, with a somewhat ascending, decumbent, or occasionally prostrate habit, it seems likely that it originated from hybridization between the diploid *L. microcarpa*, to which it is similar morphologically and with which it shares one genome, and a possibly extinct member of sect. *Dantia* with prostrate stems and opposite leaves.

Plants from the following collections are exceptionally fully prostrate and root at the nodes:

U.S.A. FLORIDA: Collier Co., 13 mi. N of U.S. 41, on U.S. 29, in vast grassy field behind roadside ditches (Big Cypress Swamp), *Peng 4268* (MO), *4273* (in part, MO).

They grow side by side with erect plants but are otherwise normal, small-fruited *L. simpsonii*, exhibiting 24 pairs of chromosomes in meiosis and setting abundant fruits with viable seeds.

Artificial hybrids between *Ludwigia simpsonii* and the diploids *L. linearis*, *L. linifolia*, *L. microcarpa*, the tetraploids *L. glandulosa*, *L. lanceolata*, the hexaploid *L. alata*, and the closely related octoploid *L. curtissii* have been synthesized, although with difficulty in some cases. Except for *L. simpsonii* × *L. curtissii*, which is highly fertile, all other combinations had 3–20% stainable pollen and produced very few, if any, seeds.

14. Ludwigia curtissii Chapman, Fl. South. U.S., 2nd edition, suppl. 621. 1883. TYPE: U.S.A. Florida: Brevard Co., ponds near Cape Malabar, July 1879, *A. H. Curtiss 922* (ho-

lotype, US-2630449; isotypes, BM, F, GH, M, MO—2 sheets, NY—3 sheets, PH, US). Figure 61.

Ludwigia spathulifolia Small, Man. Southeast. Fl. 943, 1506. 1933. TYPE: U.S.A. Florida: Dade Co., Everglades, northwest of Perrine, 16 Jan. 1909, *J. K. Small & J. J. Carter 2990* (holotype, NY).

Plants glabrous. Stems erect or ascending at base, very rarely creeping, 15–75 cm tall, single to well branched, the branches sometimes very slender; leaf bases slightly decurrent. Stolons not seen, new shoots ascending from base of the persistent, defoliated main stem of the previous year, very rarely prostrate and rooting at the nodes. Leaves variable in shape, most frequently oblanceolate-spatulate, sometimes spatulate or oblanceolate to very narrowly so, sublinear in extreme cases, 10–25(–30) mm long, 1.3–8 mm wide, glabrous, apex acute or mucronate, margin subentire with hydathodal glands, base attenuate into winged petioles 3–12 mm long. Stipules reddish purple, narrowly ovate, succulent, 0.2–0.3 mm long, 0.15–0.25 mm wide. Flowers in leaf axils, usually not congested. Sepals green with whitish, accrescent base, widely deltate or triangular, ascending, 1.5–3 mm long, 1.2–2 mm wide, apex narrowly acute or acuminate, margin entire. Petal usually lacking, 1–3 vestigial petals occasionally seen in some flowers, these yellow, narrowly elliptic, 1–2.5 mm long, 0.5–1 mm wide, apex obtuse, base attenuate. Anthers 0.3–0.55 mm long; filaments yellowish, 0.75–1(–1.25) mm long. Pollen grains shed singly. Nectary disc green, raised 0.3–0.4 mm on the ovary apex, 0.9–1.6 mm across, prominently 4-lobed, glabrous. Style greenish, 0.35–0.65 mm long; stigma yellowish, subglobose, 0.25–0.4 mm thick. Capsules obconical, (2–)2.5–4(–4.7) mm long, 2–3(–3.5) mm thick, glabrous, occasionally remotely minutely puberulent, the hairs 0.05–0.07 mm, pedicels 0.1–0.5 mm long. Bracteoles attached on opposite sides near base of capsule, narrowly lanceolate, lance-elliptic or oblong-linear, 1.5–3.5 (–4) mm long, 0.4–0.8 mm wide, swollen at base. Seeds light brown, ellipsoid, 0.45–0.6 mm long, 0.3–0.4 mm thick, the surface cells transversely elongate, glabrous, occasionally covered by waxes (?) that appear also like appressed or ascending hairs. Self-compatible. Gametic chromosome number, $n = 32$.

Distribution. *Ludwigia curtissii* grows in pine savannas and flatwoods, marshes, ponds, stream banks, sandy, peaty swales, limestone prairies, and in solution pits in limestone; it is restricted to the Bahamas and the peninsula of Florida (Fig. 60). Flowering and fruiting all year.

Representative specimens examined. U.S.A. FLORIDA: Brevard Co., near Eau Gallie, Indian River, *Curtiss 928* (FLAS). Charlotte Co., 3.5 mi. NW of Port Charlotte, *Godfrey 65356* (DS, DUKE, FLAS, FSU, LL, MSC, NCU, US, USF, VDB). Collier Co., Alligator Alley, picnic area ca. 5 mi. Grand Bahama, Pelican Lake Area, *Correll & Popenoe 51315* (MO).

Ludwigia curtissii and *L. simpsonii* are both highly variable in habit and leaf shape and are often difficult to distinguish; the only consistent distinguishing character is the size of mature capsules. These two species are unique in sect. *Microcarpium* in having loculicidal capsules and in having, along with the diploid *L. microcarpa*, more or less spatulate cauline leaves. Their capsules dehisce by four longitudinally lenticular slits opposite the loculi. When dehiscence is complete, the capsule is split into four basally united parts topped with persistent but slightly shriveled sepals. This type of capsule dehiscence is highly specialized and has an anatomical basis (Peng & Tobe, 1987). *Ludwigia curtissii* and *L. simpsonii* are also distinct in that they are the only species in sect. *Microcarpium* that rarely produce true stolons. From the perennial base of the previous-year stem they form new shoots that ascend at first and soon become erect.

Some populations of *Ludwigia curtissii* from the Everglades of southern Florida and the Bahamas tend to have larger capsules (3.5–4.7 mm long) and were named *L. spathulifolia* by Small (1933). As their variation pattern closely parallels that of *L. curtissii* s. str., and they are octoploids with $n = 32$, they are here considered as variants of the slightly smaller-fruited *L. curtissii* that do not warrant taxonomic recognition, as was suggested by Long & Lakela (1976), Raven & Tai (1979), Godfrey & Wooten (1981), and Wunderlin (1982).

Ludwigia curtissii co-occurs with *L. alata*, *L. linifolia*, *L. microcarpa*, and *L. simpsonii* and hybridizes with the diploid *L. linifolia* and *L. microcarpa*, forming F_1s that form flowers but not seeds. *Ludwigia curtissii* × *L. microcarpa* exhibited 8 bivalents and 24 univalents at meiosis. The pollen stainability was 16% (Peng, 1988). As discussed above, natural hybrids between *L. curtissii* and *L. simpsonii* probably occur but would be difficult to recognize. Like *L. simpsonii*, *L. curtissii* forms intersectional hybrids with *L. repens* ($n = 24$, sect. *Dantia*) in the field. Such plants are vigorous and somewhat prostrate or suberect; they have alternate and opposite or subopposite leaves, but do not form viable seeds.

In the experimental greenhouse, artificial hybrids have been synthesized between *Ludwigia curtissii* and the diploid *L. linearis* and the tetraploids *L. glandulosa*, *L. lanceolata*, *L. pilosa*, *L. polycarpa*, *L. sphaerocarpa*, and *L. suffruticosa*. A few seeds were occasionally produced by some of the octoploid × tetraploid hybrids.

Compared with *Ludwigia simpsonii* ($n = 24$), *L. curtissii* ($n = 32$) is generally taller, more robust, more often erect, tends to have narrower and longer leaves, and nearly always has larger flowers and capsules. Further, the leaves of *L. curtissii* are nearly always alternate throughout, and the flowers occasionally have one to three vestigial petals. As these two species have three genomes in common (Peng, 1988), it is apparent that *L. curtissii* originated following hybridization between *L. simpsonii* and a diploid, petaliferous, erect species with narrow and alternate leaves, larger flowers, and longer capsules. The likely candidate for such a plant is only to be found in *L. linearis*, *L. linifolia*, the Cuban endemic *L. stricta*, or their progenitors. Indeed it is even possible that more than one of the above species hybridized with *L. simpsonii* in the past to form the present-day *L. curtissii*. If this is true, the morphological variability observed in *L. curtissii* is expected.

TWO NEW SPECIES OF THE *LUPINUS LANATUS* COMPLEX[1]

Ana Maria Planchuelo[2] *and David B. Dunn*[3]

Abstract

The *Lupinus lanatus* complex is a group of closely related species that grow in southeastern Brazil and northeastern Argentina. They are herbaceous, perennial or occasionally biennial plants with basal leaves in the juvenile plant simple or three-foliate, stipules 3–7 cm long or longer, and large flowers 15–20 mm long having the banner glabrous and well reflexed from the wings. Two species, *L. magnistipulatus* and *L. setifolius*, are described for the first time.

This group of species appears to be closely related and can be recognized by the large stipules 3–7 cm or more long and the presence of some simple or trifoliate leaves at the base of the juvenile plants. Completely developed leaves from adult plants have five or more leaflets. They are all herbaceous perennials or short-lived perennials, or occasionally function as biennials. The flowers are commonly 15–20 mm long and glabrous, with the banner well reflexed from the wings and the sides turned back. The calyx cup tapers into the pedicel without the gibbous enlargement that is commonly present in other lupines.

We are suggesting that this group of species forms a second lineage derived from *L. paraguariensis*, which is thought to be the origin of the group, since it possesses morphological characteristics reminiscent of the group, including that the juvenile leaves and the first leaf produced on the lateral branches are simple. Planchuelo & Dunn (1984) described *L. paraguariensis* as showing a transitional stage between simple- and compound-leaved species.

Lupinus lanatus has floccose lanate indument on both sides of the leaflets (see Fig. 1A). Vegetatively it has been described as forming perennial mats up to four feet in diameter in sand dunes, with new growth developing seasonally from the tips of the stems which survive under the sand. *Lupinus magnistipulatus*, described in this paper, is similar to *L. lanatus* in the perennial condition but has less lanate hair coating (see Fig. 1B), and as its name suggests, the former develops a much larger free tip on the stipules. *Lupinus setifolius*, also described in this paper, appears to be biennial. The large free tip of the stipules and the loss of the lanate indument (see Fig. 1C) suggest the latter as a derivative from *L. magnistipulatus*.

The species *L. multiflorus*, *L. albescens*, and *L. aureonitens*, treated by Planchuelo & Dunn (1984), are relatives of this complex. They have caespitose perennial habit and a narrow free tip of the stipules like *L. lanatus* but develop a much denser indument that grades from densely short-lanate to densely sericeous, completely hiding the leaf surface.

Key to the Species of *Lupinus lanatus* Complex and Relatives

1a. Basal leaves and first leaf of each lateral branch simple, the others palmately compound ..... *L. paraguariensis* (description in Planchuelo & Dunn, 1984).

1b. All leaves of mature plants palmately compound, exceptionally with few basal simple leaves on juvenile plants.

2a. Wing tips with an upturned toothlike tip.

3a. Leaves primarily cauline; stems erect, branching above ..... *L. albescens* (description in Planchuelo & Dunn, 1984).

3b. Leaves primarily basal; stems with branches primarily basal ..... *L. aureonitens* (description in Planchuelo & Dunn, 1984).

[1] The authors wish to express their appreciation to Dr. John Dwyer for reviewing the Latin descriptions, to Mr. John Myers for helping with the illustrations, and to the curators of DS, K, LIL, MO, NY, SI, UC, UMO, and US for the loan of the materials.

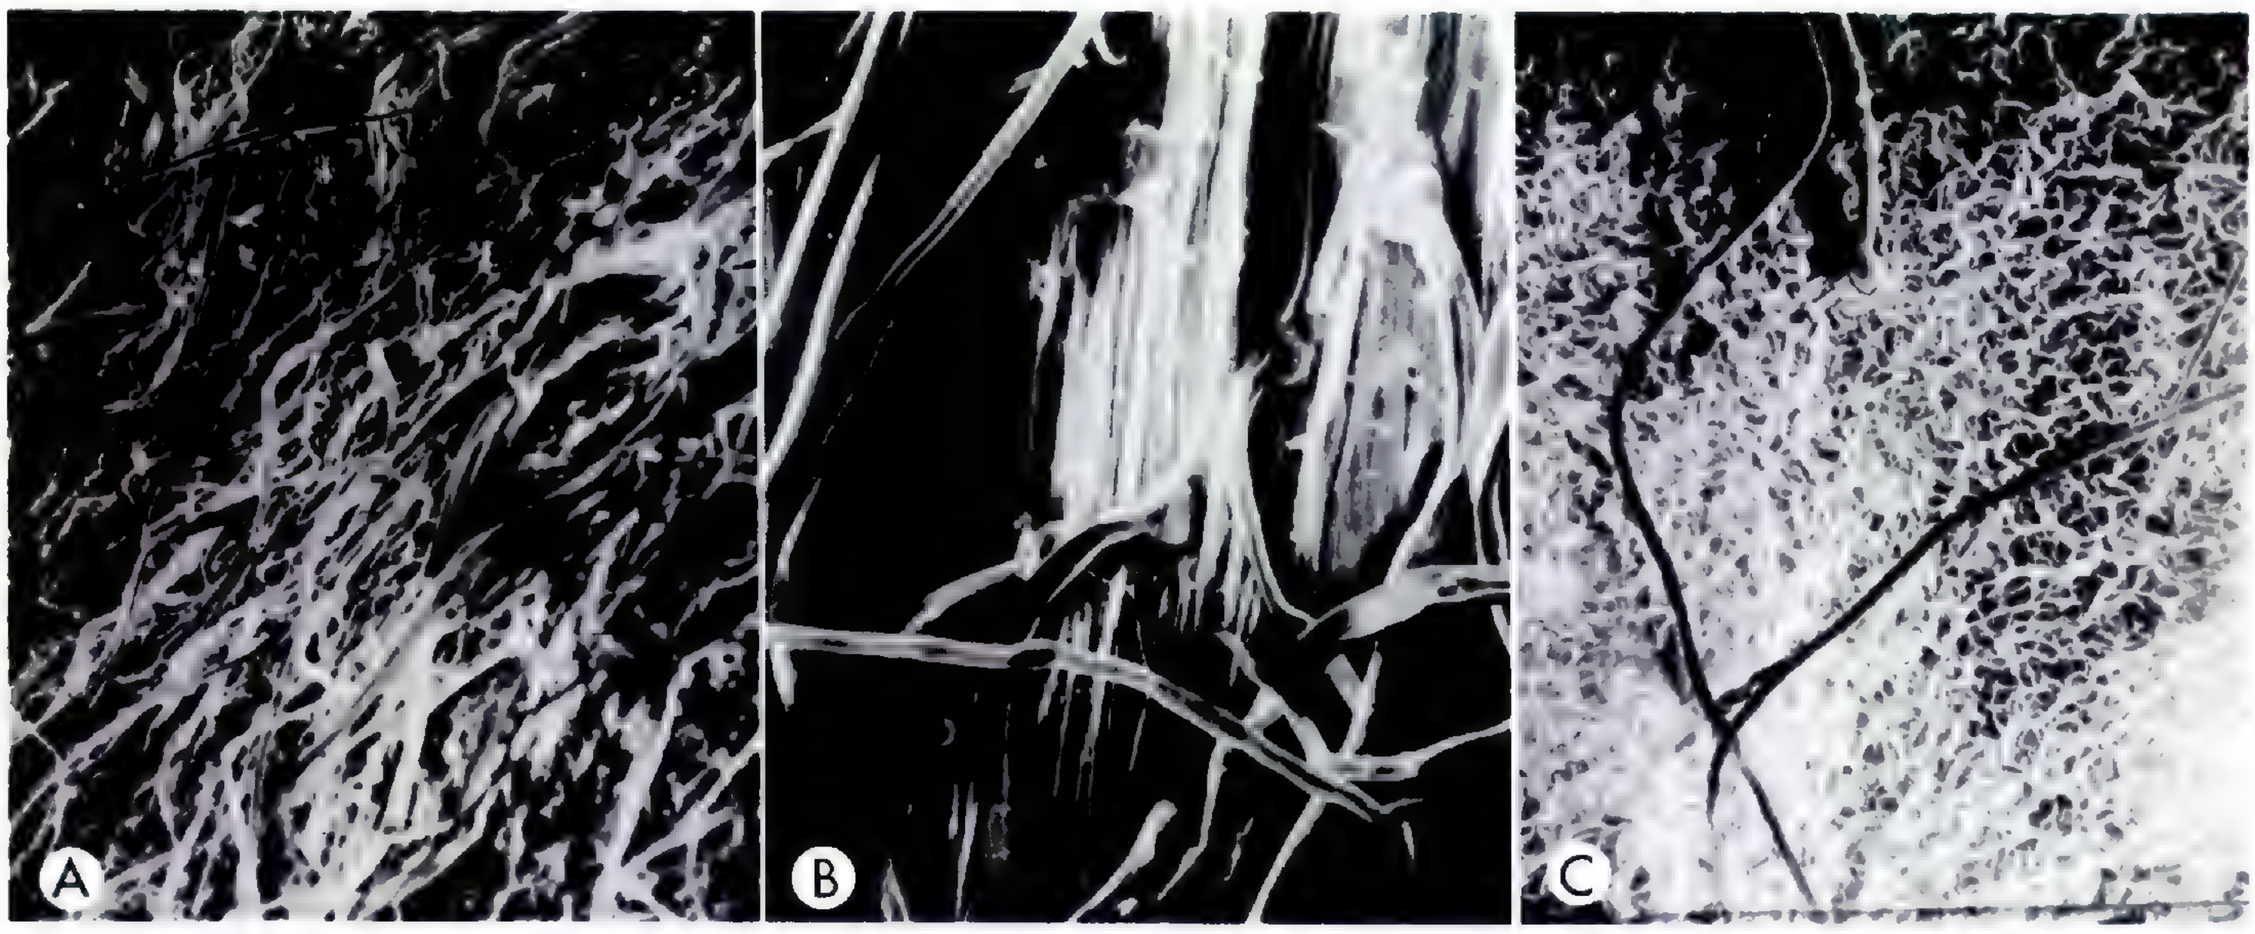

FIGURE 1. Indument of:—A. *L. lanatus*, leaflet (×100).—B. *L. magnistipulatus*, petiole (×200).—C. *L. setifolius*, leaflet (×100).

2b. Wing tips rounded, without a toothlike tip.
4a. Leaflets mostly broadly obovate or broadly oblanceolate with the tips rounded. Stipules foliaceous, with free portion ovate-lanceolate, 8–15 mm wide.
5a. Leaflets thinly floccose-lanate on both sides. Short-lived perennials ..... 2. *L. magnistipulatus*
5b. Leaflets glabrous on both sides except for setaceous hairs on the midrib, major veins, and occasionally scattered along some areas of the margins. Biennials ..... 3. *L. setifolius*
4b. Leaflets all narrowly elliptic to narrowly oblanceolate with tips acute or obtuse. Stipules not foliaceous, with free portion lance-attenuate, 2–5 mm exceptionally 6 mm wide.
6a. Leaflets abundantly floccose-lanate or thinly lanate, the larger 7–11 cm long. Stipules 3–8.5 cm long. Lower lip of the calyx often enlarging and foliaceous as fruit develops ... 1. *L. lanatus*
6b. Leaflets densely lanate to densely sericeous, the larger 4–5 cm long, rarely to 7 cm long. Stipules 1.5–2.6 cm long. Calyx not enlarging as fruit develops ..... *L. multiflorus* (description in Planchuelo & Dunn, 1984).

1. Lupinus lanatus Benth. in Mart., Fl. Brasil. 15(1): 16. 1859. TYPE: Brazil. Rio Grande do Sul: *Herb. Imp. Bras. 1511*, not seen. Figure 2.

Plants perennial, herbaceous, 25–60 cm tall, in clumps to 1.5 m wide, possibly rhizomatous or the stems arising from underground branches; *stems* fistulose, 8–12 mm diam., first internode of branches 4–9 cm long, others 1–2 cm long, covered with soft tangled lanate hairs 4–5 mm long; *stipules* 3–8.5 cm long, commonly green like the leaflets, the free portion lance-attenuate, 3–5(6) cm long, 2–5(6) mm wide, with pubescence as on stems; *petioles* 5–22 cm long, lanate as stems; *leaflets* 5–7, oblanceolate, the tips obtuse or rounded, densely or thinly lanate on both sides, thinner above, the largest 7–11 cm long, 10–20 mm wide. *Peduncles* 2.5–8 cm long, fistulose, angular and lanate as the stems; *racemes* 15–50 cm long, flowers scattered, the rachis fistulose and lanate as stems; *bracts* caducous, lance-attenuate, 12–22 mm long, lanate dorsally, glabrous ventrally; *bracteoles* 3–5 mm long, lanceolate to lance-attenuate, attached just below the lips of the lateral sinuses of the calyx; *pedicels* 1–2 mm long at anthesis, 4–6 mm long in fruit, lanate. *Calyces* lanate outside, glabrous within, the base tapering into the pedicel, lower lip 13–17 mm long, 3.2–4.5 mm wide, often enlarging and foliaceous as fruit develops, trifid, central tooth 2.5–4 mm long, lateral teeth 2–3 mm long, arching outward, upper lip 8–13 mm long, bifid, the slit 5.6–9 mm deep, the lobes 2.3–2.5 mm wide, the lips connate 3 mm; *banner* glabrous, oval-ovate, 15–17.5 mm long, including the 2–2.5-mm-long claw, 12–13.5 mm wide, appressed 4–6 mm, reflexed 12–13 mm, reflexed/appressed ratio 2.4, the angle 130°, the tip bluntly rounded; *wings* arcuate, 15.5–18.5 mm long, 6.5–7.5 mm wide, the claw 3.5 mm long, lobe above the claw 1.6–2.2 mm wide; *keel* arcuate glabrous, 4.5 mm wide in the middle, the tip arcing back in a continuous curve, no definite angle, 80–85°; *ovules* 8. *Legumes* ascending to erect, 5–9 cm long, 1–1.5 cm wide, shaggy lanate.

The floral parts, especially the calyx and the banner, are remarkably similar to those of *L. paraguariensis*. The Argentinian specimens and *Rambo 28195* from Rio Grande do Sul, Brazil, had

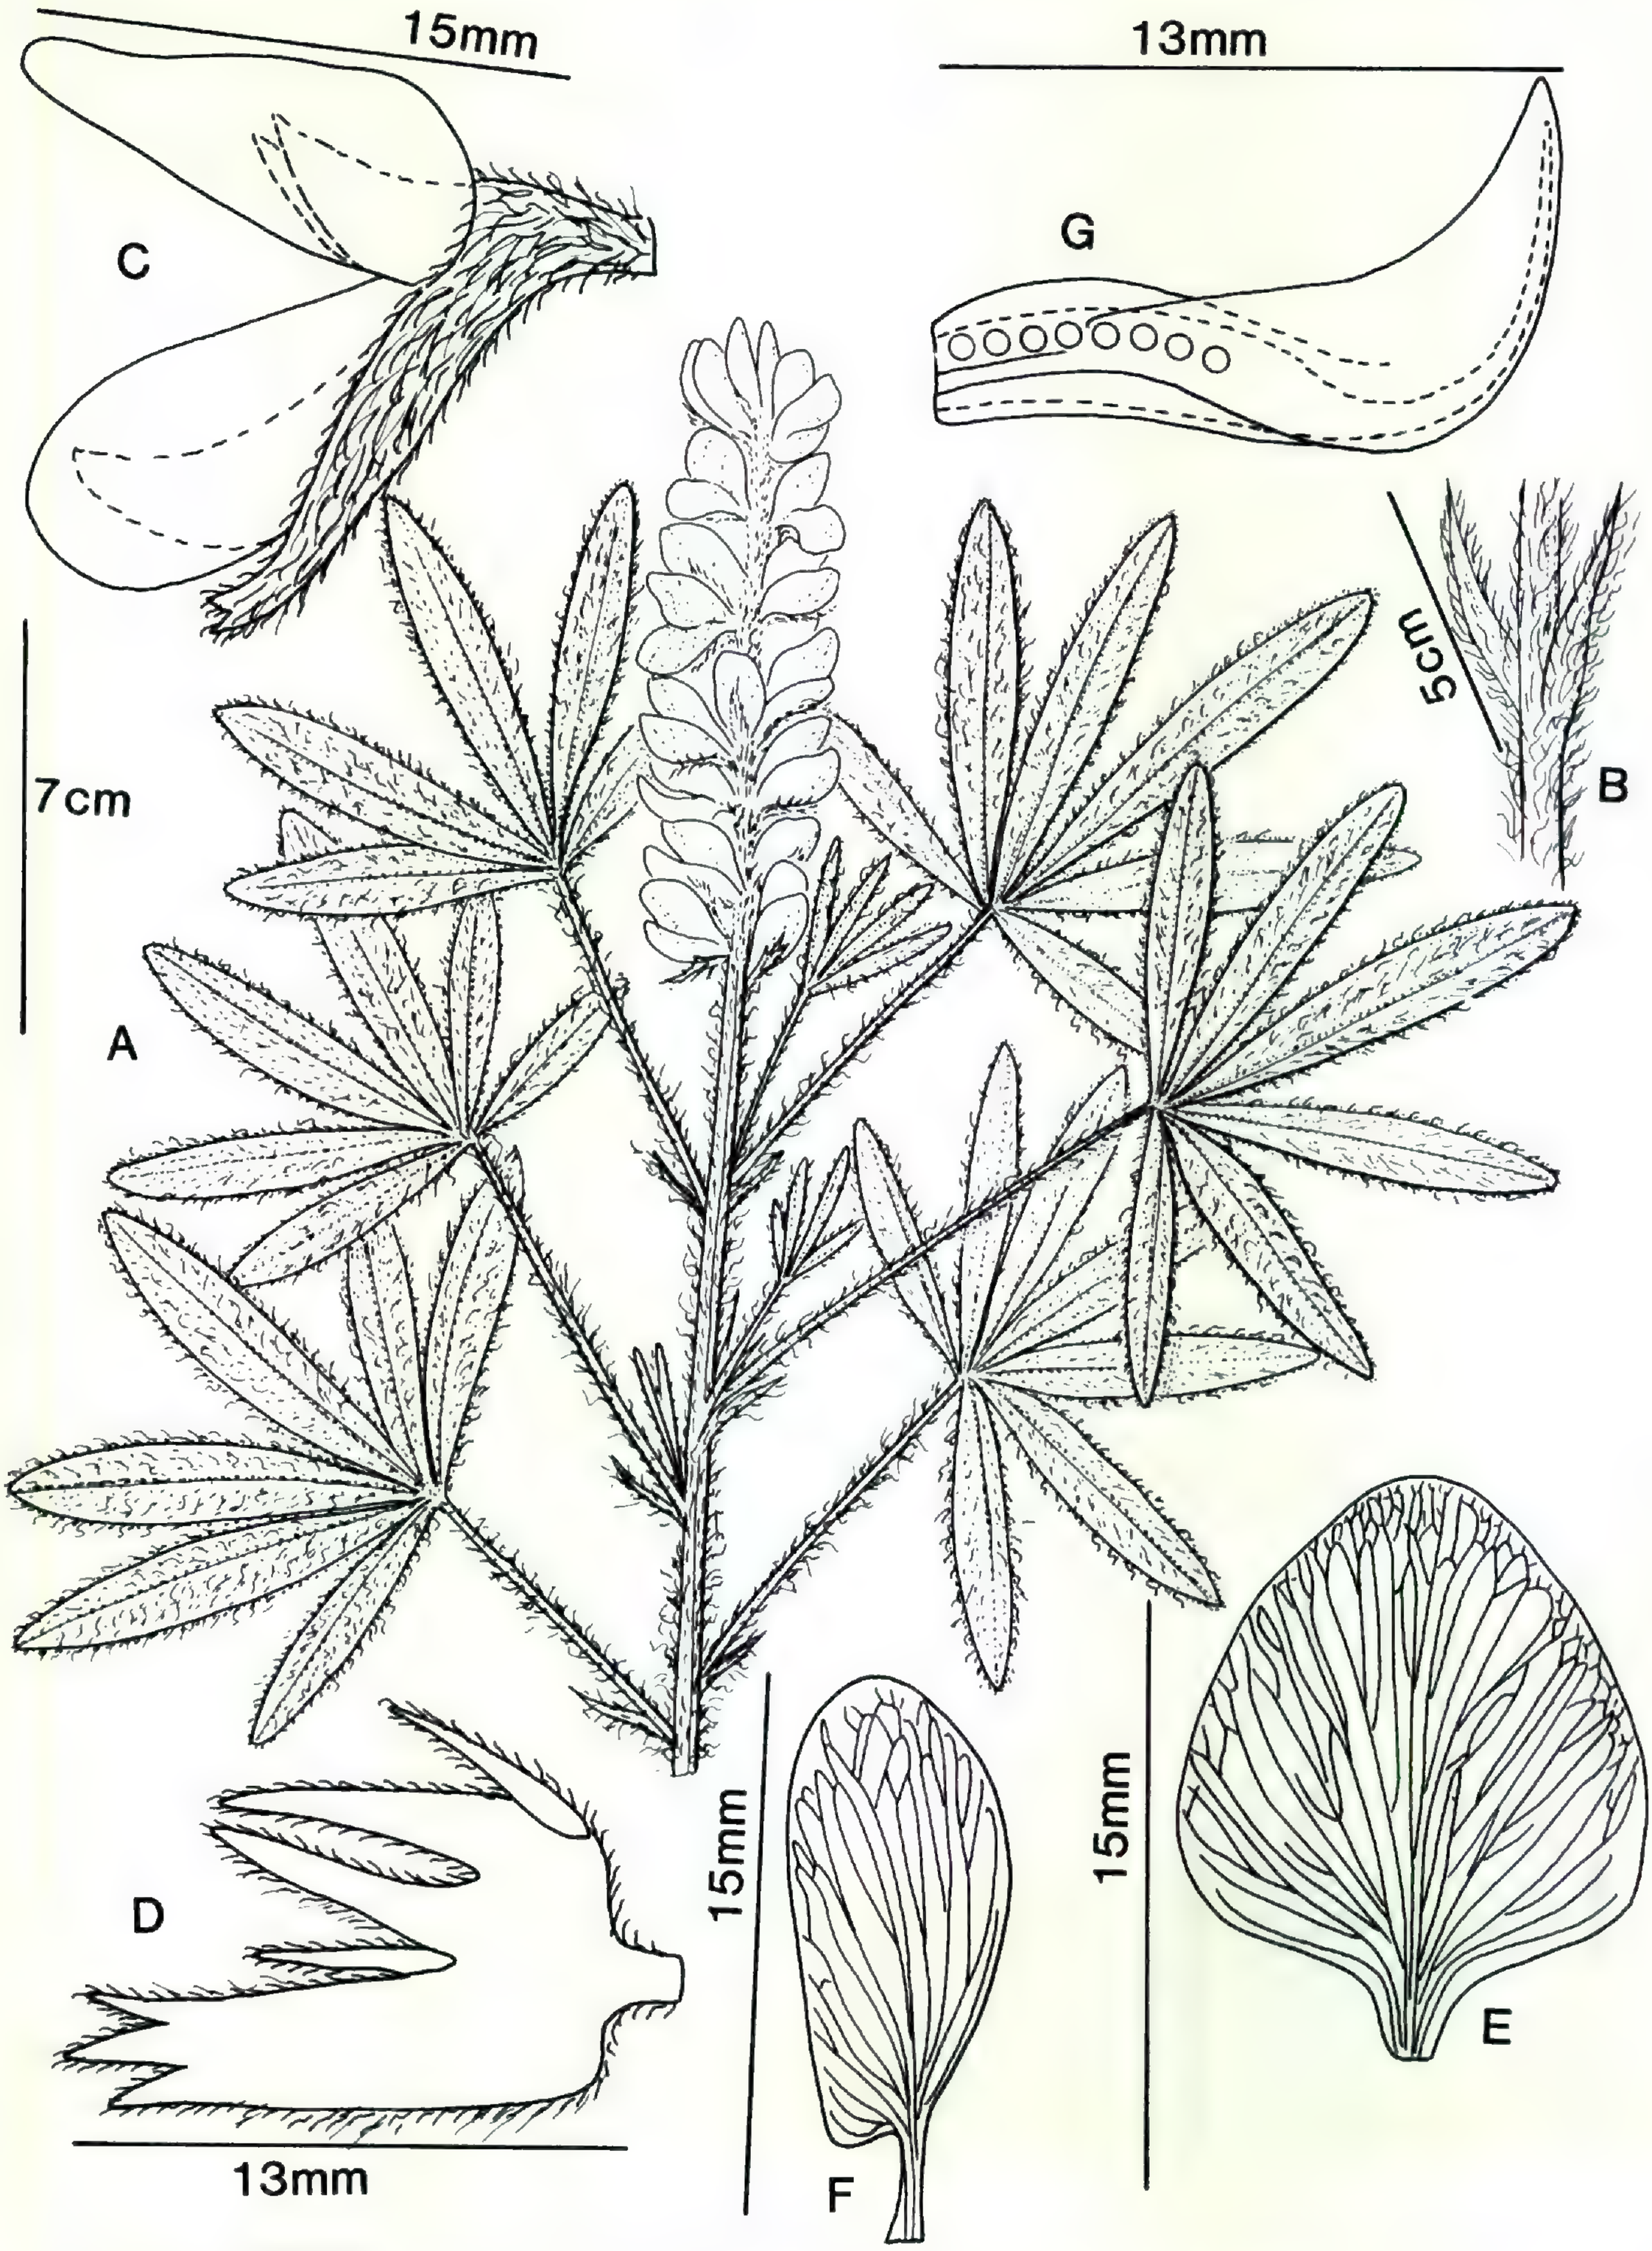

FIGURE 2. Illustration of typical structures of *Lupinus lanatus*. —A. Upper part of the plant with inflorescence. —B. Stipules detached at the node. —C. Lateral view of the left side of the flower. —D. Calyx, cut at the left lateral sinus and opened so that the inside surface shows. —E. Banner petal flattened, dorsal view. —F. Wing petal. —G. Keel petals, enclosing the staminal tube and the pistil, with the mean number of ovules drawn.

unusually large stipules, some of them 6 mm wide. All the others have most of the stipules under 5 mm wide. Although all the morphological characteristics of the large-stipuled specimens are those of the species, the enlargement of the free tip of the stipules suggests relationship with *L. magnistipulatus* and even crossing between the two species.

Lupinus lanatus occurs in the southernmost states of Brazil and in Misiones, Argentina. The plants are reported growing in open places and dunes.

Representative specimens examined. ARGENTINA. MISIONES: Campo Grande, *Bertoni 638* (LIL); Dep. Concepción, Concepción, *Schulz 6965* (LIL); Dep. San Javier, Parambí, collector's name illegible, *Inst. Miguel Lillo 188188* (LIL). BRAZIL: locality unknown, *Sello 3032* (NY, UC). 2. Lupinus magnistipulatus Planchuelo & Dunn, sp. nov. TYPE: Brazil. Santa Catarina: Campos dos Padres, 1,900 m, *R. Reitz 2377* (holotype, SI; isotype, RB; photo, UMO). Figure 3.

Plantae perennes, 17–35 cm altae; *caules* erecti, fistulosi, pagina multis pilis patentibus, 4–7 mm longis ornata; *stipulae* virides foliaceae, 4–7 cm longae, parte adnata 1.2–2 cm longa, parte libera divergenti et ascendenti, 2–5 cm longa, 8–15 mm lata, lanata; petiolis 4–8.5(11) cm longi, lanati; *folia* (3)5–9-palmata, foliolis lanatis, oblanceolatis, apice rotundatis, 5–7 cm longis, 15–20 mm latis, complanatis; *racemus* major 20–30 cm longus, floribus diffusis; *bractae* foliolaceae, lanceolatae, apice acuminatae, 12–23 mm longae, 2.5–4 mm latae, in dorso lanatae; bracteolae 3.5–6 mm longae, 0.5–1.2 mm latae; *flores calycibus* in dorso lanatis, ventraliter glabris, labio inferiore triangulare, 10–16.6 mm longo, 3.5–4 mm lato, tridentato, dentibus 1.7–4.5 mm longis, lateralibus brevibus, labium superiore 7–10.6 mm longo, bifido, incisura 5–7.8 mm profunda, lobis 2.5–3 mm latis; *vexilum* glabrum, ovatum, 15.5–20.6 mm longum, 9.7–15.6 mm latum, ungue 3.4–4.5 mm longo, parte reflexa 9–13.5 mm; *alae* 13–21 mm longae, 6.4–11 mm latae, ungue 3.3–4.5 mm longo; *carina* glabra, 3.4–5.5 mm lata; *ovula* 4–8; *legumina* lanata, immatura, 5 cm longa, 7 mm lata; *semina* non visa.

Plants short-lived perennials, 17–35 cm tall; *stem* erect, simple or with some basal branches, more often branching from the upper nodes after the first inflorescence, hollow, angular, to somewhat fistulose, covered with soft, spreading, tangled hairs 4–7 mm long; *stipules* 4–7 cm long, membranaceous, encircling ca. 40% of the stem circumference, 1.2–2 cm fused to the petioles, the free portion green, foliaceous, ovate-lanceolate, diverging away and ascending, 2–5 cm long, 8–15 mm wide, thinly lanate on both sides; *petioles* 4–8.5(11) cm long, lanate as the stems; basal juvenile leaves simple, the rest compound; *leaflets* (3)5–9, broadly oblanceolate, the tips generally rounded, lanate on both sides, the largest 5–7 cm long, 15–20 mm wide, mostly complanate at maturity. *Peduncles* 4–6 cm long on the primary inflorescence; *racemes* all immature on the primary inflorescences, 20–30 cm long, flowers scattered to subverticillate, the rachis lanate; *bracts* green, foliaceous, caducous, lanceolate, the tips acuminate, largest below, smaller above, 12–23 mm long, 2.5–4 mm wide, lanate dorsally; *bracteoles* lanceolate, 3.5–6 mm long, 0.5–1.2 mm wide, attached near or slightly below the lips of the lateral sinuses of the calyx; *pedicels* 2.6–5 mm long, ascending lanate. *Calyces* lanate outside, glabrous within, the lower lip triangular, 10–16.6 mm long, 3.5–4 mm wide, the tip trifid, the teeth 1.7–4.5 mm long, the laterals only slightly shorter, the upper lip 7–10.6 mm long, deeply bifid, the notch 5–7.8 mm deep, the lobes 2.5–3 mm wide, the lips connate 2.8–4.5 mm laterally; *banners* glabrous, ovate, 15.5–20.6 mm long, including the 3.4–4.5-mm-long claw, 9.7–15.6 mm wide, reflexed 9–13.5 mm, appressed 5.8–9.5 mm, reflexed/appressed ratio 1.45–1.6, the angle 127–144°; *wings* 13–21 mm long, 6.4–11 mm wide, the claw 3.3–4.5 mm long; *keels* glabrous, 3.4–5.5 mm wide in the middle, the angle 96–103°; *ovules* 4–8. *Legumes* shaggy lanate, immature, 5 cm long, 7 mm wide; *seeds* not seen.

The name *Lupinus magnistipulatus* was suggested several years ago by Prof. A. Burkart on herbarium specimens. Some of the specimens cited here were labeled by Burkart as a new species, *L. reitzii*. Our interpretation of the material is that these specimens are juvenile plants and do not differ otherwise from the others. Therefore we have not recognized *L. reitzii*.

The new species apparently grows only in southeastern Brazil in the states of Santa Catarina and Paraná at altitudes from 700 to 1,650 m. Flowering occurs from late October to late January.

Representative specimens examined. BRAZIL. PARANÁ: Mun. Guarapuana, Guara, *Hatchback & Guimaraes 20492* (NY, US). SANTA CATARINA: Mun. Bom. 3. Lupinus setifolius Planchuelo & Dunn, sp. nov. TYPE: Brazil. Rio Grande do Sul: locality unknown, *Rambo 36208* (holotype, SI; photos, NY, UMO, US). Figure 4.

Plantae probabiliter biennes, 25–30 cm altae; *caules* erecti, fistulosi, pilis paucis patentibus ornatis; *stipulae* virides, foliaceae, 5–6 cm longae, parte adnata, 1.5–2 cm longa, parte libera lanceolato-ovata, glabrata, 2.5–4 cm longa, 10–15 mm lata; *petioli* 6–7.5 cm longi; *folia* 5–7-palmata, folia juvenalia basi plantae locata et folia prima ramorum lateralium foliolis tribus notata, eis late oblanceolatis; *foliola* 6–7 cm longa, 20–25 mm lata, apice rotundatis ubique glabris praeter marginem et costam infra pilis patulis setaceis ornatis; *racemus* densus, floribus diffusis; *bractae* 13–20 mm longae, 3–5 mm latae, margine setaceo; bracteolae 3.7–4.8 mm longae, 0.8–1 mm latae; *flores calycibus* in dorso laxe subsericeis, ventraliter glabris, labio inferiore 10–11.3 mm longo, 3–4 mm lato, tridentato, dentibus 2.3–3 mm longis, 0.5–0.8 mm latis, labio superiore 7.5–8 mm longo, bifido, incisura 4.5–5 mm profunda, lobis 1.2–1.5 mm latis, *vexillum* glabrum, ovatum, 15.5–16.5 mm longum, 11.5–12.5 mm latum, ungue 3–3.5 mm longo, parte reflexa

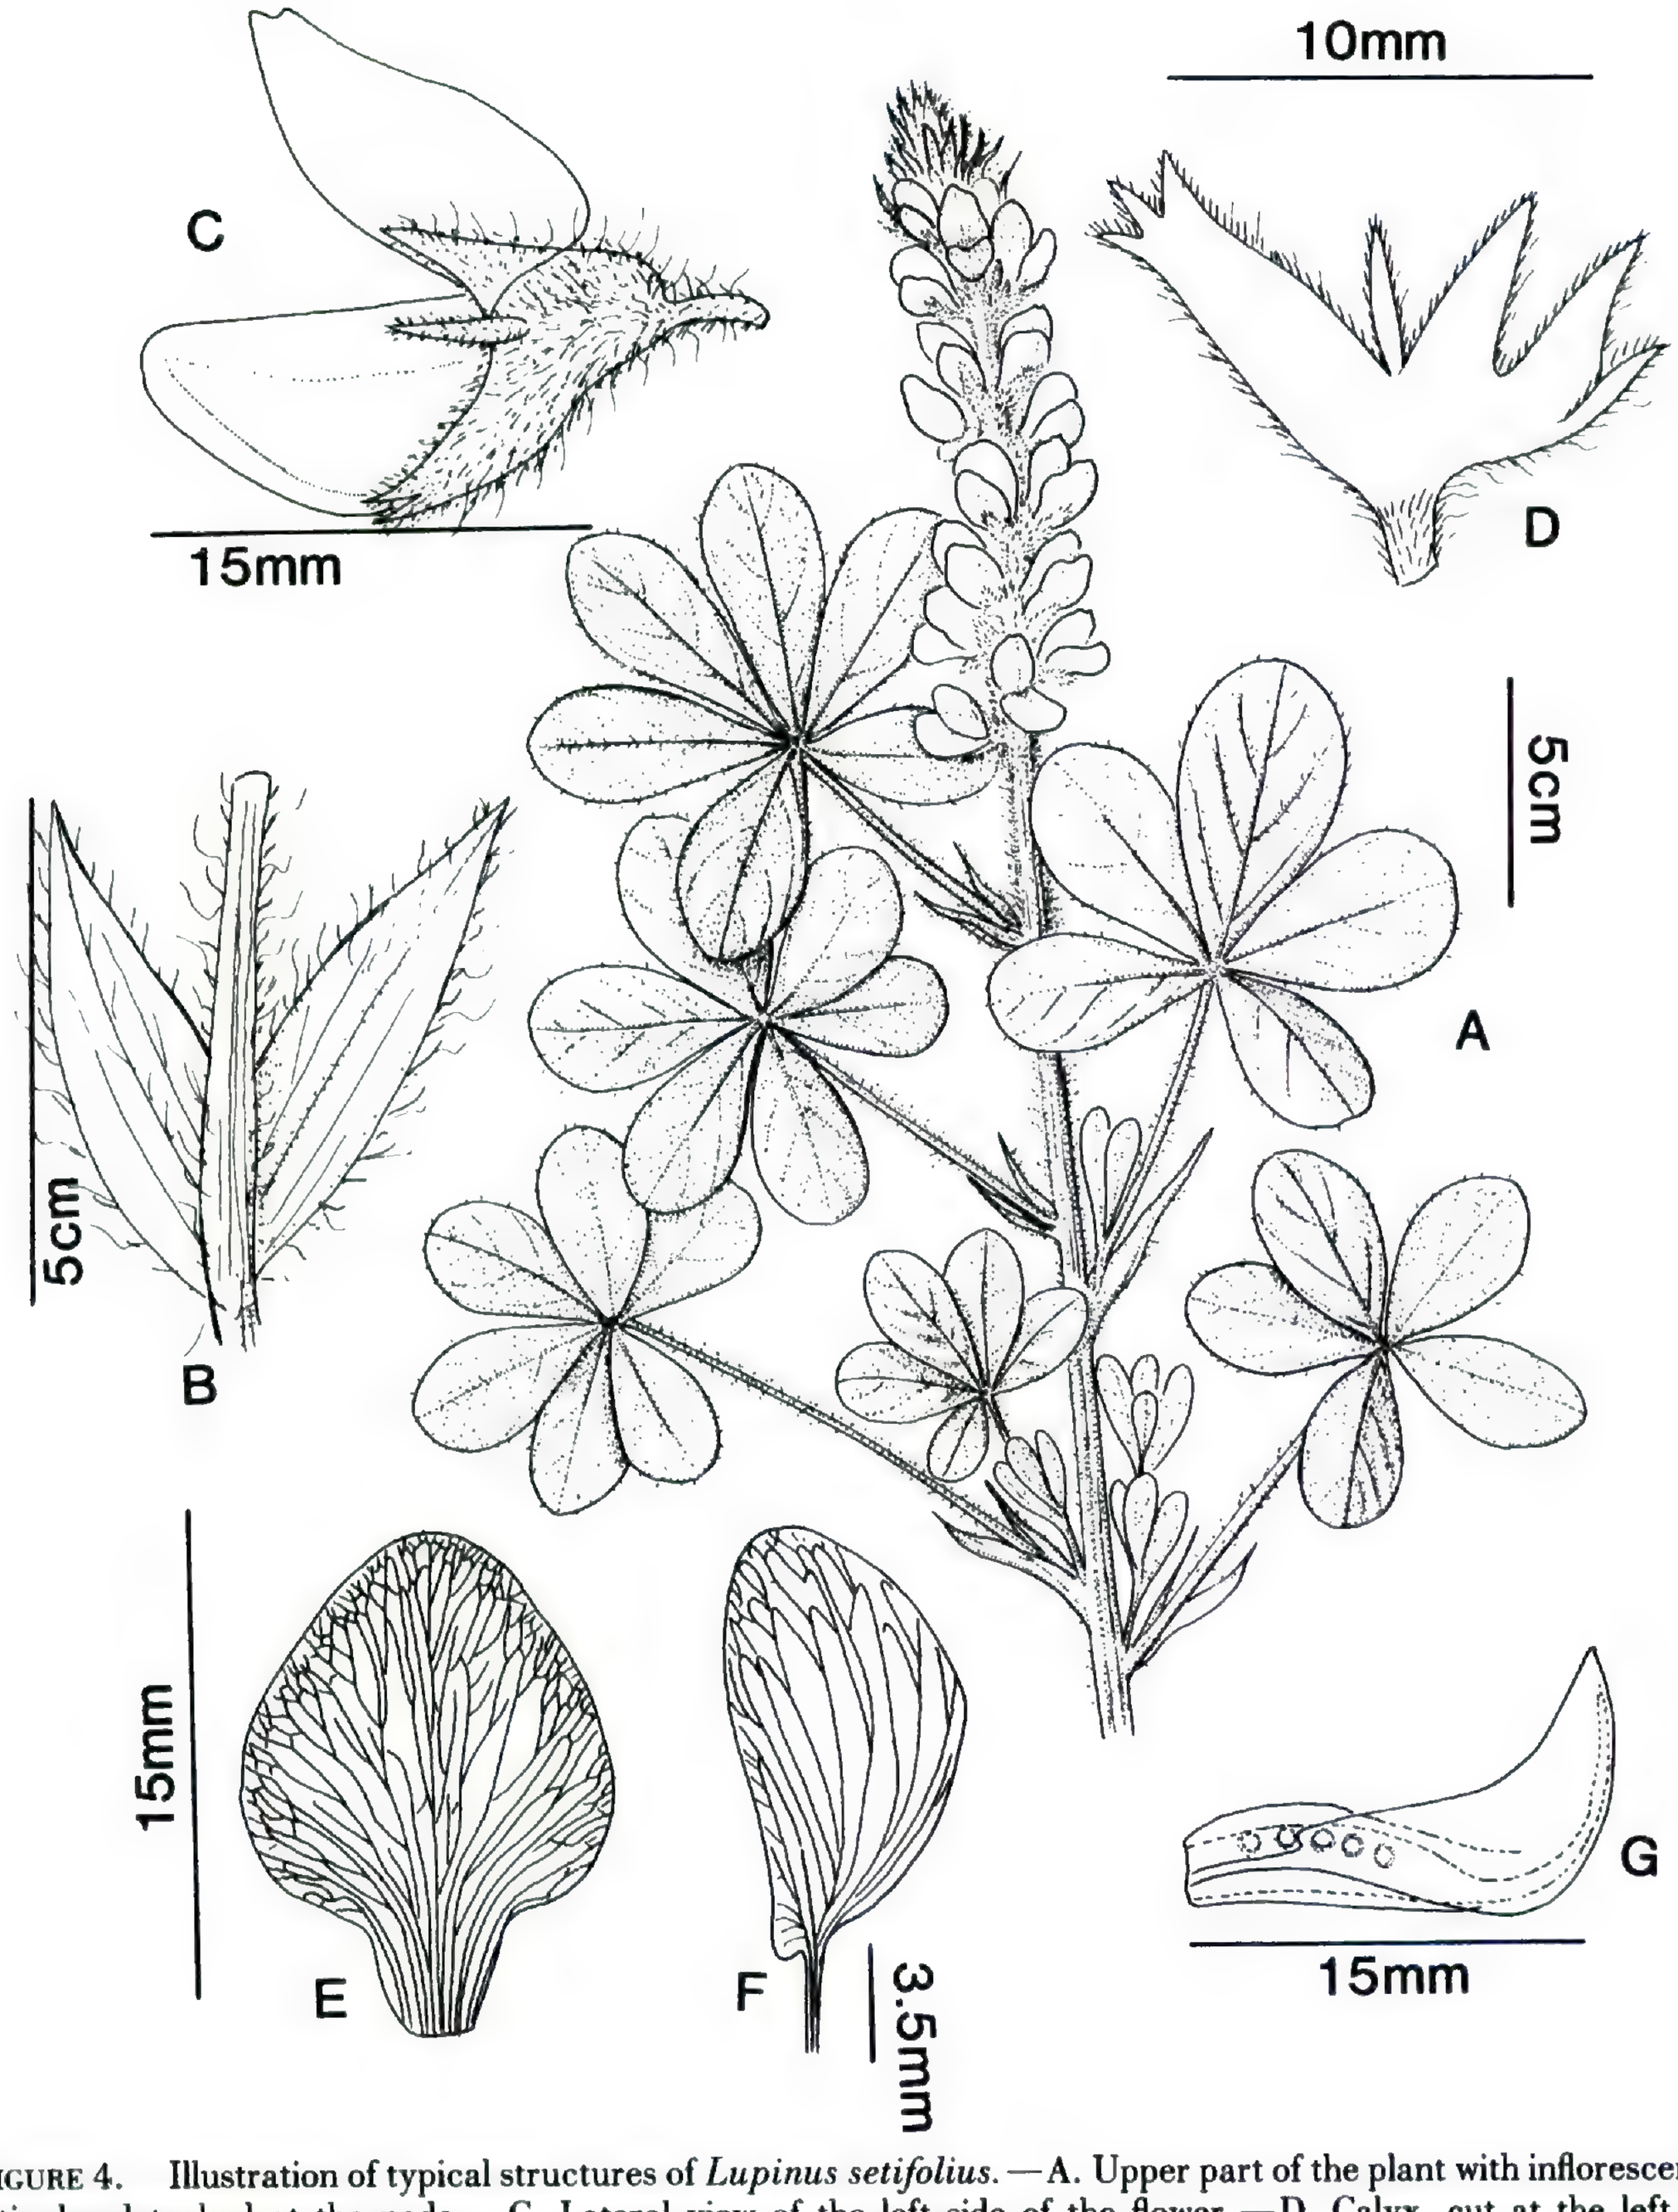

FIGURE 4. Illustration of typical structures of *Lupinus setifolius*. —A. Upper part of the plant with inflorescence.—B. Stipules detached at the node.—C. Lateral view of the left side of the flower.—D. Calyx, cut at the left lateral sinus and opened so that the inside surface shows.—E. Banner petal flattened, dorsal view.—F. Wing petal.—G. Keel petals, enclosing the staminal tube and the pistil, with the mean number of ovules drawn.

11–12 mm; *alae* 16–16.5 mm longae, 5.8–6.5 mm latae; *carina* glabra, 3.5–4.5 mm lata; *ovula* 5–6; legumina non visa.

Plants probably biennial, ca. 25–30 cm tall; *stems* erect, fistulose, 6–7 mm diam., angular from the ridges by veins from the petioles, with scattered spreading hairs 3–4 mm long, these more numerous above; *stipules* foliaceous, 5–6 cm long, the adnate portion 1.5–2 cm long, the free portion ovate-lanceolate, the tip acute or obtuse, 2.5–4 cm long, 10–15 mm wide, glabrous on both sides except a few hairs on the veins and margins; *petioles* of larger leaves 6–7.5 cm long; juvenile *leaves* at the base of the plant and first leaves of lateral branches with 3 leaflets, the upper leaves with 5–7 leaflets, these broadly oblanceolate, the tips

rounded, glabrous on both sides, except a few spreading hairs on the veins below or on the margin, the largest 6–7 cm long, 20–25 mm wide, mostly complanate. *Peduncle* 5 cm long, with more numerous spreading hairs than the stem; *raceme* (immature) dense, the flowers scattered; *rachis* with denser spreading hairs; *bracts* lanceolate, the tips acuminate, 13–20 mm long, 3–5 mm wide, dorsally pubescent on the veins, glabrous ventrally on the lower half; bracteoles 3.7–4.8 mm long, 0.8–1 mm wide, glabrous with margin setaceous, narrowly lanceolate, attached just below the lips of the lateral sinuses of the calyx; *pedicels* 3 mm long at anthesis, spreading pilose. *Calyces* covered with long soft hairs outside, glabrous within, the base tapering but slightly gibbous above, lower lip 10–11.3 mm long, 3–4 mm wide, the tip trifid, all teeth 2.3–3 mm long, 0.5–0.8 mm wide, upper lip 7.5–8 mm long, 4 mm wide, bifid, the notch 4.5–5 mm deep, the lobes 1.2–1.5 mm wide; *banner* glabrous, ovate, the base tapering into a claw, 15.5–16.5 mm long including the 3–3.5-mm-long claw, 11.5–12.5 mm wide, reflexed 11–12 mm, appressed 4–5 mm, reflexed/appressed ratio 2.2–3, the angle double, the lower 132–146°; *wings* 16–16.5 mm long, 5.8–6.5 mm wide, the tip rounded, the claw 3.5–3.8 mm long; *keel* glabrous, 3.5–4.5 mm wide in the middle, the angle 92–109°, the tip not curled back; *ovules* 5–6. *Legumes* not seen.

The description was based solely on the holotype. The taxon appears to be closely related to *L. magnistipulatus*. The flowers are smaller and the base of the calyx has a ridge above and below at the pedicel, while that of *L. magnistipulatus* tapers more gradually into the pedicel.

Representative specimen examined. BRAZIL. RIO GRANDE DO SUL: locality unknown, *Rambo 36208* (holotype, SI; photos, NY, UMO, US).

CONCLUSIONS

The three species, *L. paraguariensis*, *L. albescens*, and *L. aureonitens*, not treated in this paper are included in the key to facilitate identification of presumably closely related species. In seedlings of *L. albescens* grown from an herbarium specimen, the first leaf of the plant was simple and the second three-foliate. This particular characteristic should be common to the group of species treated in the key, although it is difficult to find in herbarium specimens. Considering the taxonomic studies of the genus *Lupinus* for South America (Planchuelo-Ravelo, 1984), this complex and its related species are representatives of the lupines of the "Atlantic Region" and are the only group of perennial plants with large compound leaves growing in the area.

AUGUSTUS FENDLER'S VENEZUELAN PLANT COLLECTIONS[1]

Carol A. Todzia[2]

ABSTRACT

Between 1854 and 1858, Augustus Fendler resided in Colonia Tovar, a German village in the Coastal Cordillera of Venezuela, where he assembled one of the finest collections of plant specimens for his time. Fendler's life in Colonia Tovar is described from his correspondence with Daniel C. Eaton, Asa Gray, George Engelmann, and Joseph Henry. Because of his devotion to plant collecting and his acute powers of observation, Fendler's 2,630 flowering plant specimens from Venezuela are extremely valuable; 223 (8.5% of his total collections) have been designated as types. Although most specimens were labeled as having been collected in Colonia Tovar, state of Aragua, Venezuela, Fendler's field notebooks cite many different localities in the states of Carabobo and Aragua, and in the Distrito Federal. A map and list of Fendler's collecting localities are provided. An annotated list including collection data extracted from his notebook is given for the angiosperm types that he collected.

In the mid nineteenth century South America was poorly known botanically compared with most other parts of the world. At this time, plants generally were collected by people who traveled through one or several countries, making plant specimens along their way (e.g., Ruíz & Pavón; Humboldt & Bonpland). Few collectors lived in an area long enough to sample a region thoroughly and collect the relatively rare species. Augustus Fendler was a notable exception. He resided four years in Colonia Tovar,[3] a small German colony 35 miles west of Caracas, Venezuela (Rasmussen, 1943), and collected over 3,000 ferns and flowering plants. These collections are noteworthy, not only for their excellence, but also because a great number of new species were based on his material. To this day, new species are being described from Fendler's Venezuelan specimens (e.g., Croat & Lambert, 1986).

Although his Venezuelan collections are extremely important, Augustus Fendler is perhaps best known for his collections of New Mexican plants between 1846 and 1847. Gray (1849) published an annotated list of Fendler's New Mexican plants, which Shaw (1982) discussed more recently. Fendler's other collecting trips to Panama, Venezuela, and Trinidad are not as well known as those he took in the United States. In Panama, Fendler (Fig. 1) collected near the Chagres River for four months in 1849 and 1850. He resided in Trinidad from 1877 until his death in 1883. His most valuable collections were made in Venezuela between January 1854, and September 1858.

This paper is an account of Fendler's life in Venezuela constructed from his letters to D. C. Eaton, G. Engelmann, and A. Gray in the Yale University Library, Missouri Botanical Garden, and Gray Herbarium archives, respectively. This correspondence provides insight not only into Fendler, but also into the difficulties of life as a plant collector in the 1800s. Fendler corresponded with Engelmann in German and with Eaton and Gray in English. These lucid and detailed letters are a chronicle of plant collecting in South America in the mid nineteenth century and are even more remarkable since German was Fendler's native language.

According to various biographical notes (Canby,

[1] This work was supported by a National Museum Act Curatorial Trainee Grant to the Missouri Botanical Garden. I am grateful to M. Riley (MO), M. Hill (YU), and the librarians at the Gray Herbarium and Arnold Arboretum for assistance with archives. A. R. Smith, J. Steyermark, and J. Ewan provided stimulating discussion on Fendler. I thank P. Berry, C. Blaney, J. E. Ewan, B. Hammel, R. C. Moran, N. Morin, G. K. Rogers, A. R. Smith, W. D. Stevens, and H. van der Werff for helpful comments on the manuscript; R. Magill and M. Crosby for computer assistance; and J. Myers for preparation of the map.

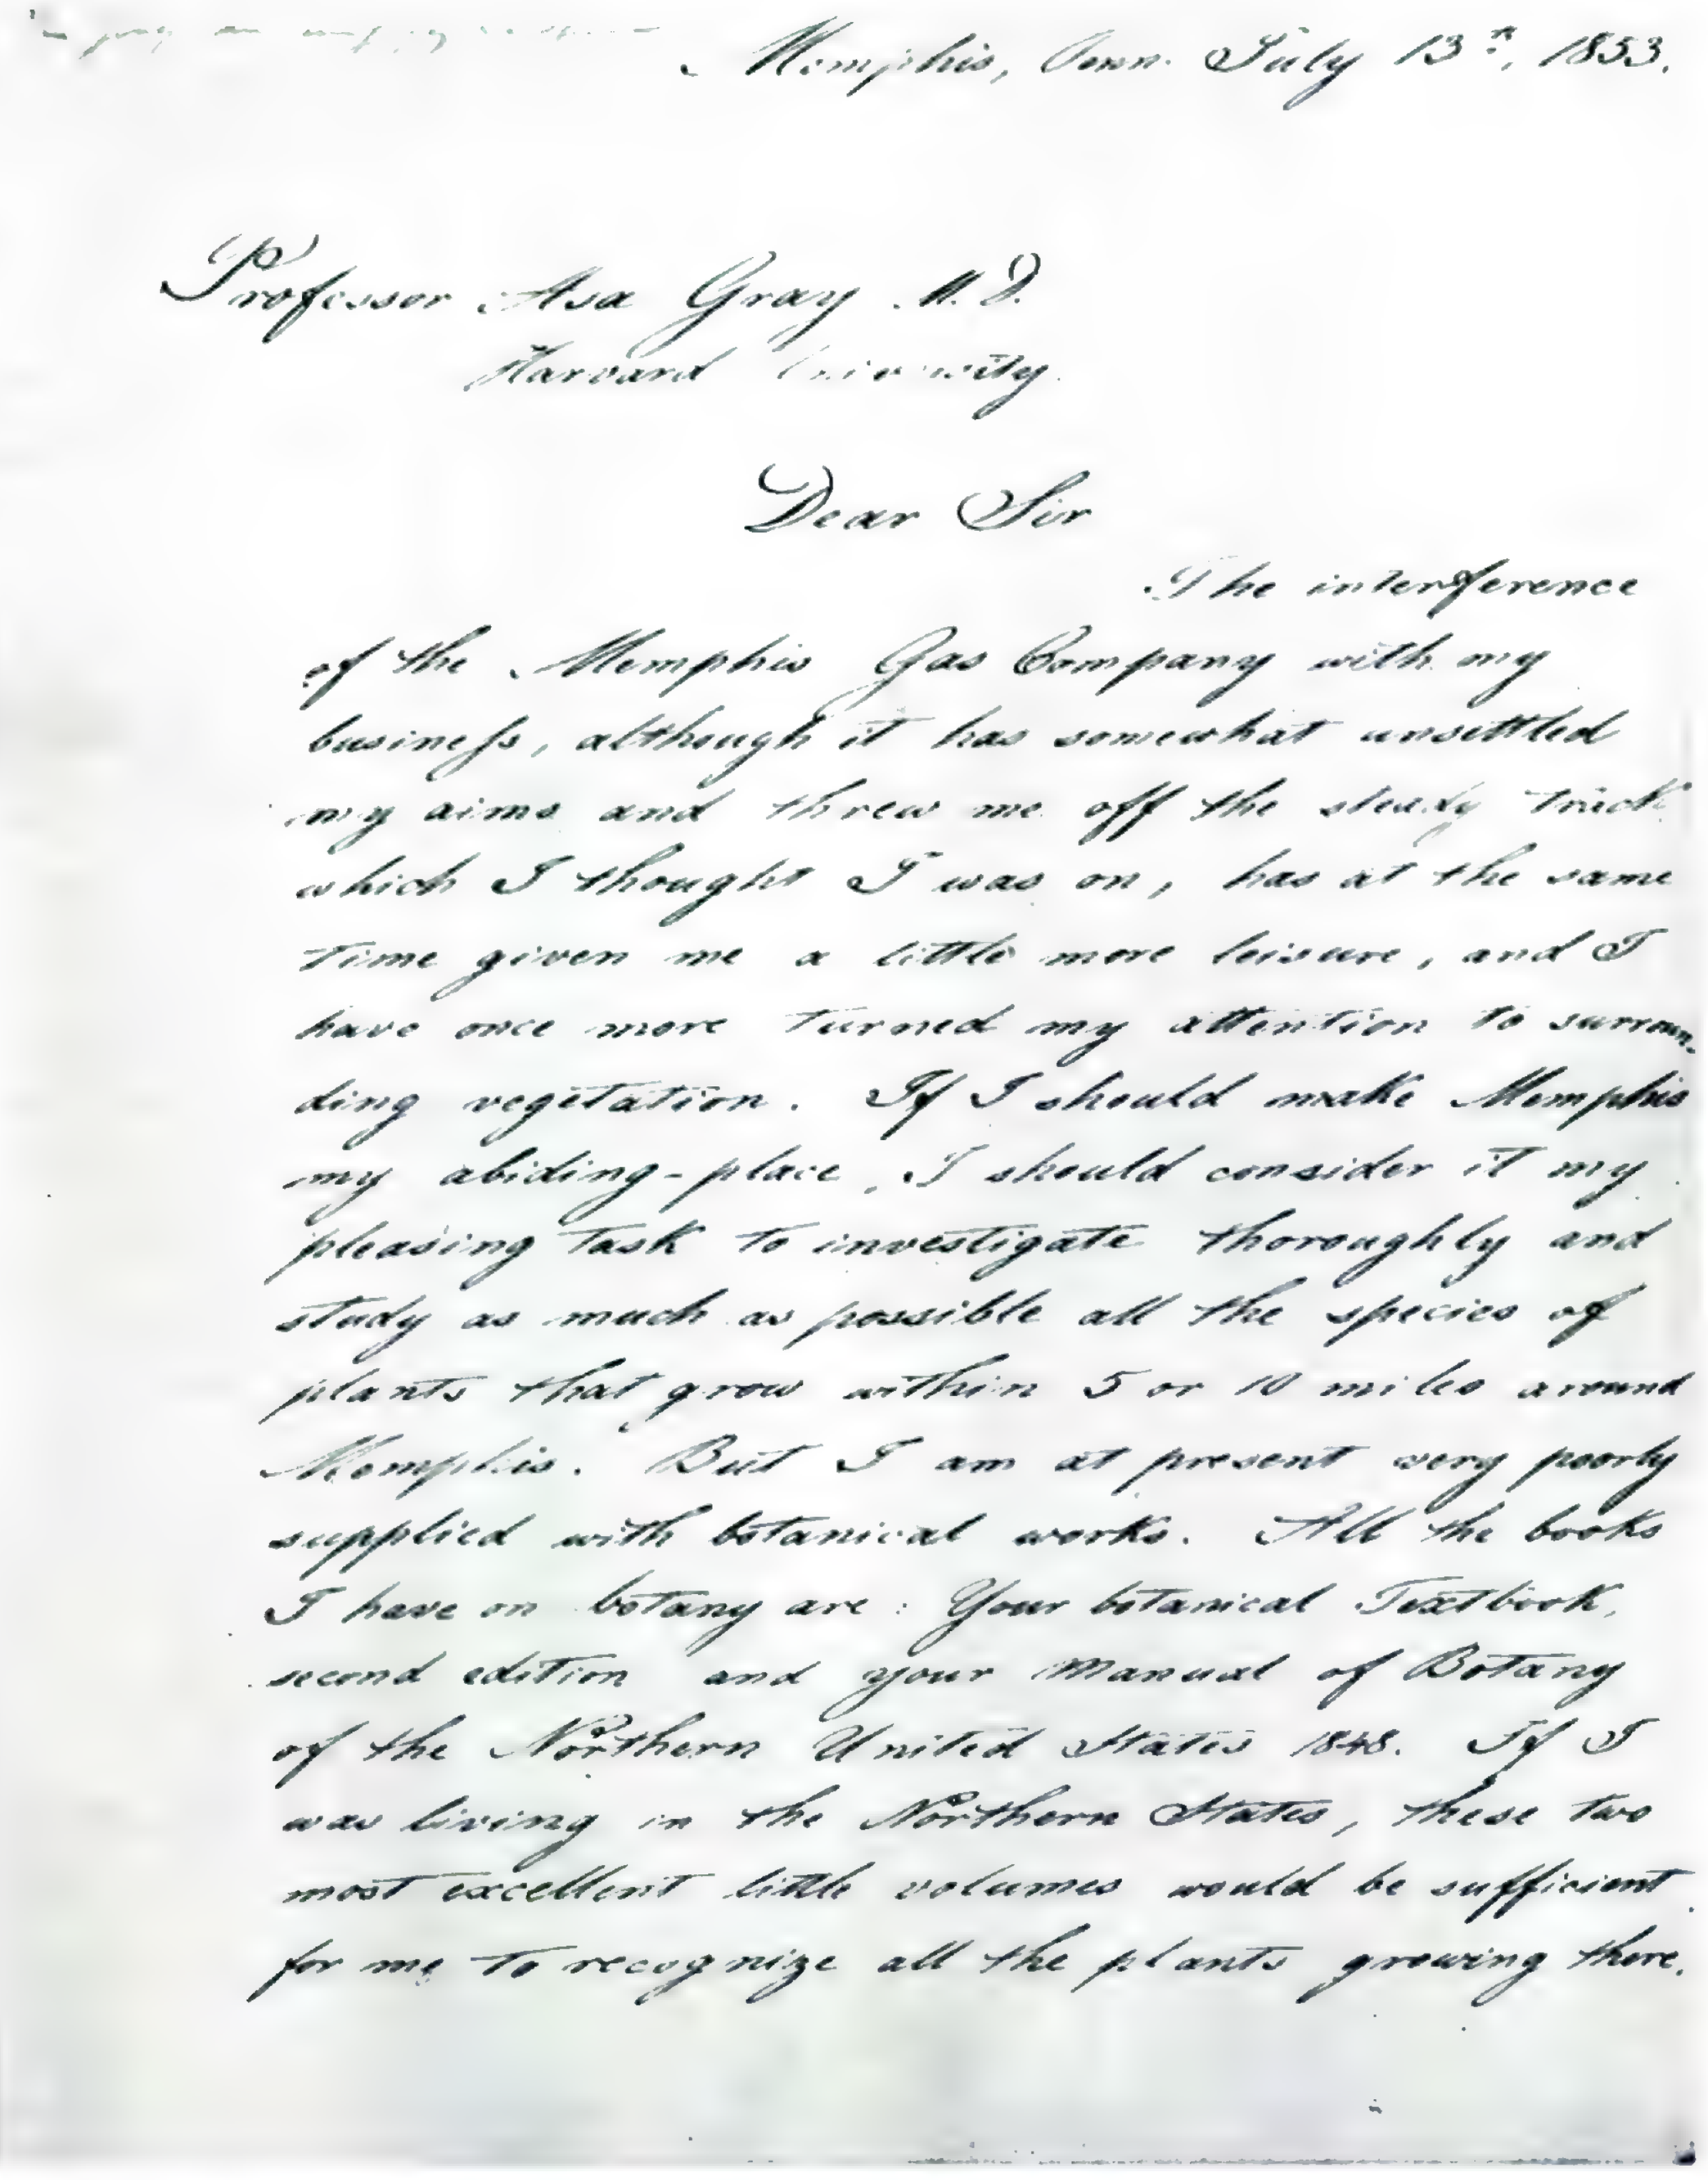
[3] Colonia Tovar is located in the state of Aragua and is not to be confused with Tovar in the state of Mérida, in the western part of Venezuela (Steyermark, 1981).

FIGURE 1. Photograph of Augustus Fendler probably taken in St. Louis, ca. 1860.

1885; Gray, 1885; Rohl, 1944), Fendler was born in Gumbinnen, eastern Prussia, in January 1813. At the age of 12 he was sent to a preparatory school where he mastered the fine penmanship that was as delightful to his correspondents as it is to his present-day historians (Fig. 2). Fascinated with traveling, Fendler sailed from Bremen to Baltimore in 1836 and within two years moved to St. Louis. During a visit to Europe in 1844, Fendler met Professor Ernst Meyer of the University at Koenigsberg in Prussia, who encouraged him to collect plants in the western United States and send them to him for sale. On his return to St. Louis, Fendler brought his specimens for identification to George Engelmann, the botanist who advised Henry Shaw, founder of the Missouri Botanical Garden (Stieber & Lange, 1986). Fendler and Engelmann struck up a friendship that spanned nearly 40 years. Engelmann later introduced Fendler to Asa Gray, who described Fendler as "a close, accurate observer, a capital collector and specimen-maker" (J. L. Gray, 1893: 341).

After a year of plant collecting in New Mexico, a failed attempt to collect plants near the Great Salt Lake, and two sojourns in Arkansas and Louisiana, Fendler settled in Memphis, Tennessee in



Memphis, Tenn. July 13th 1853.

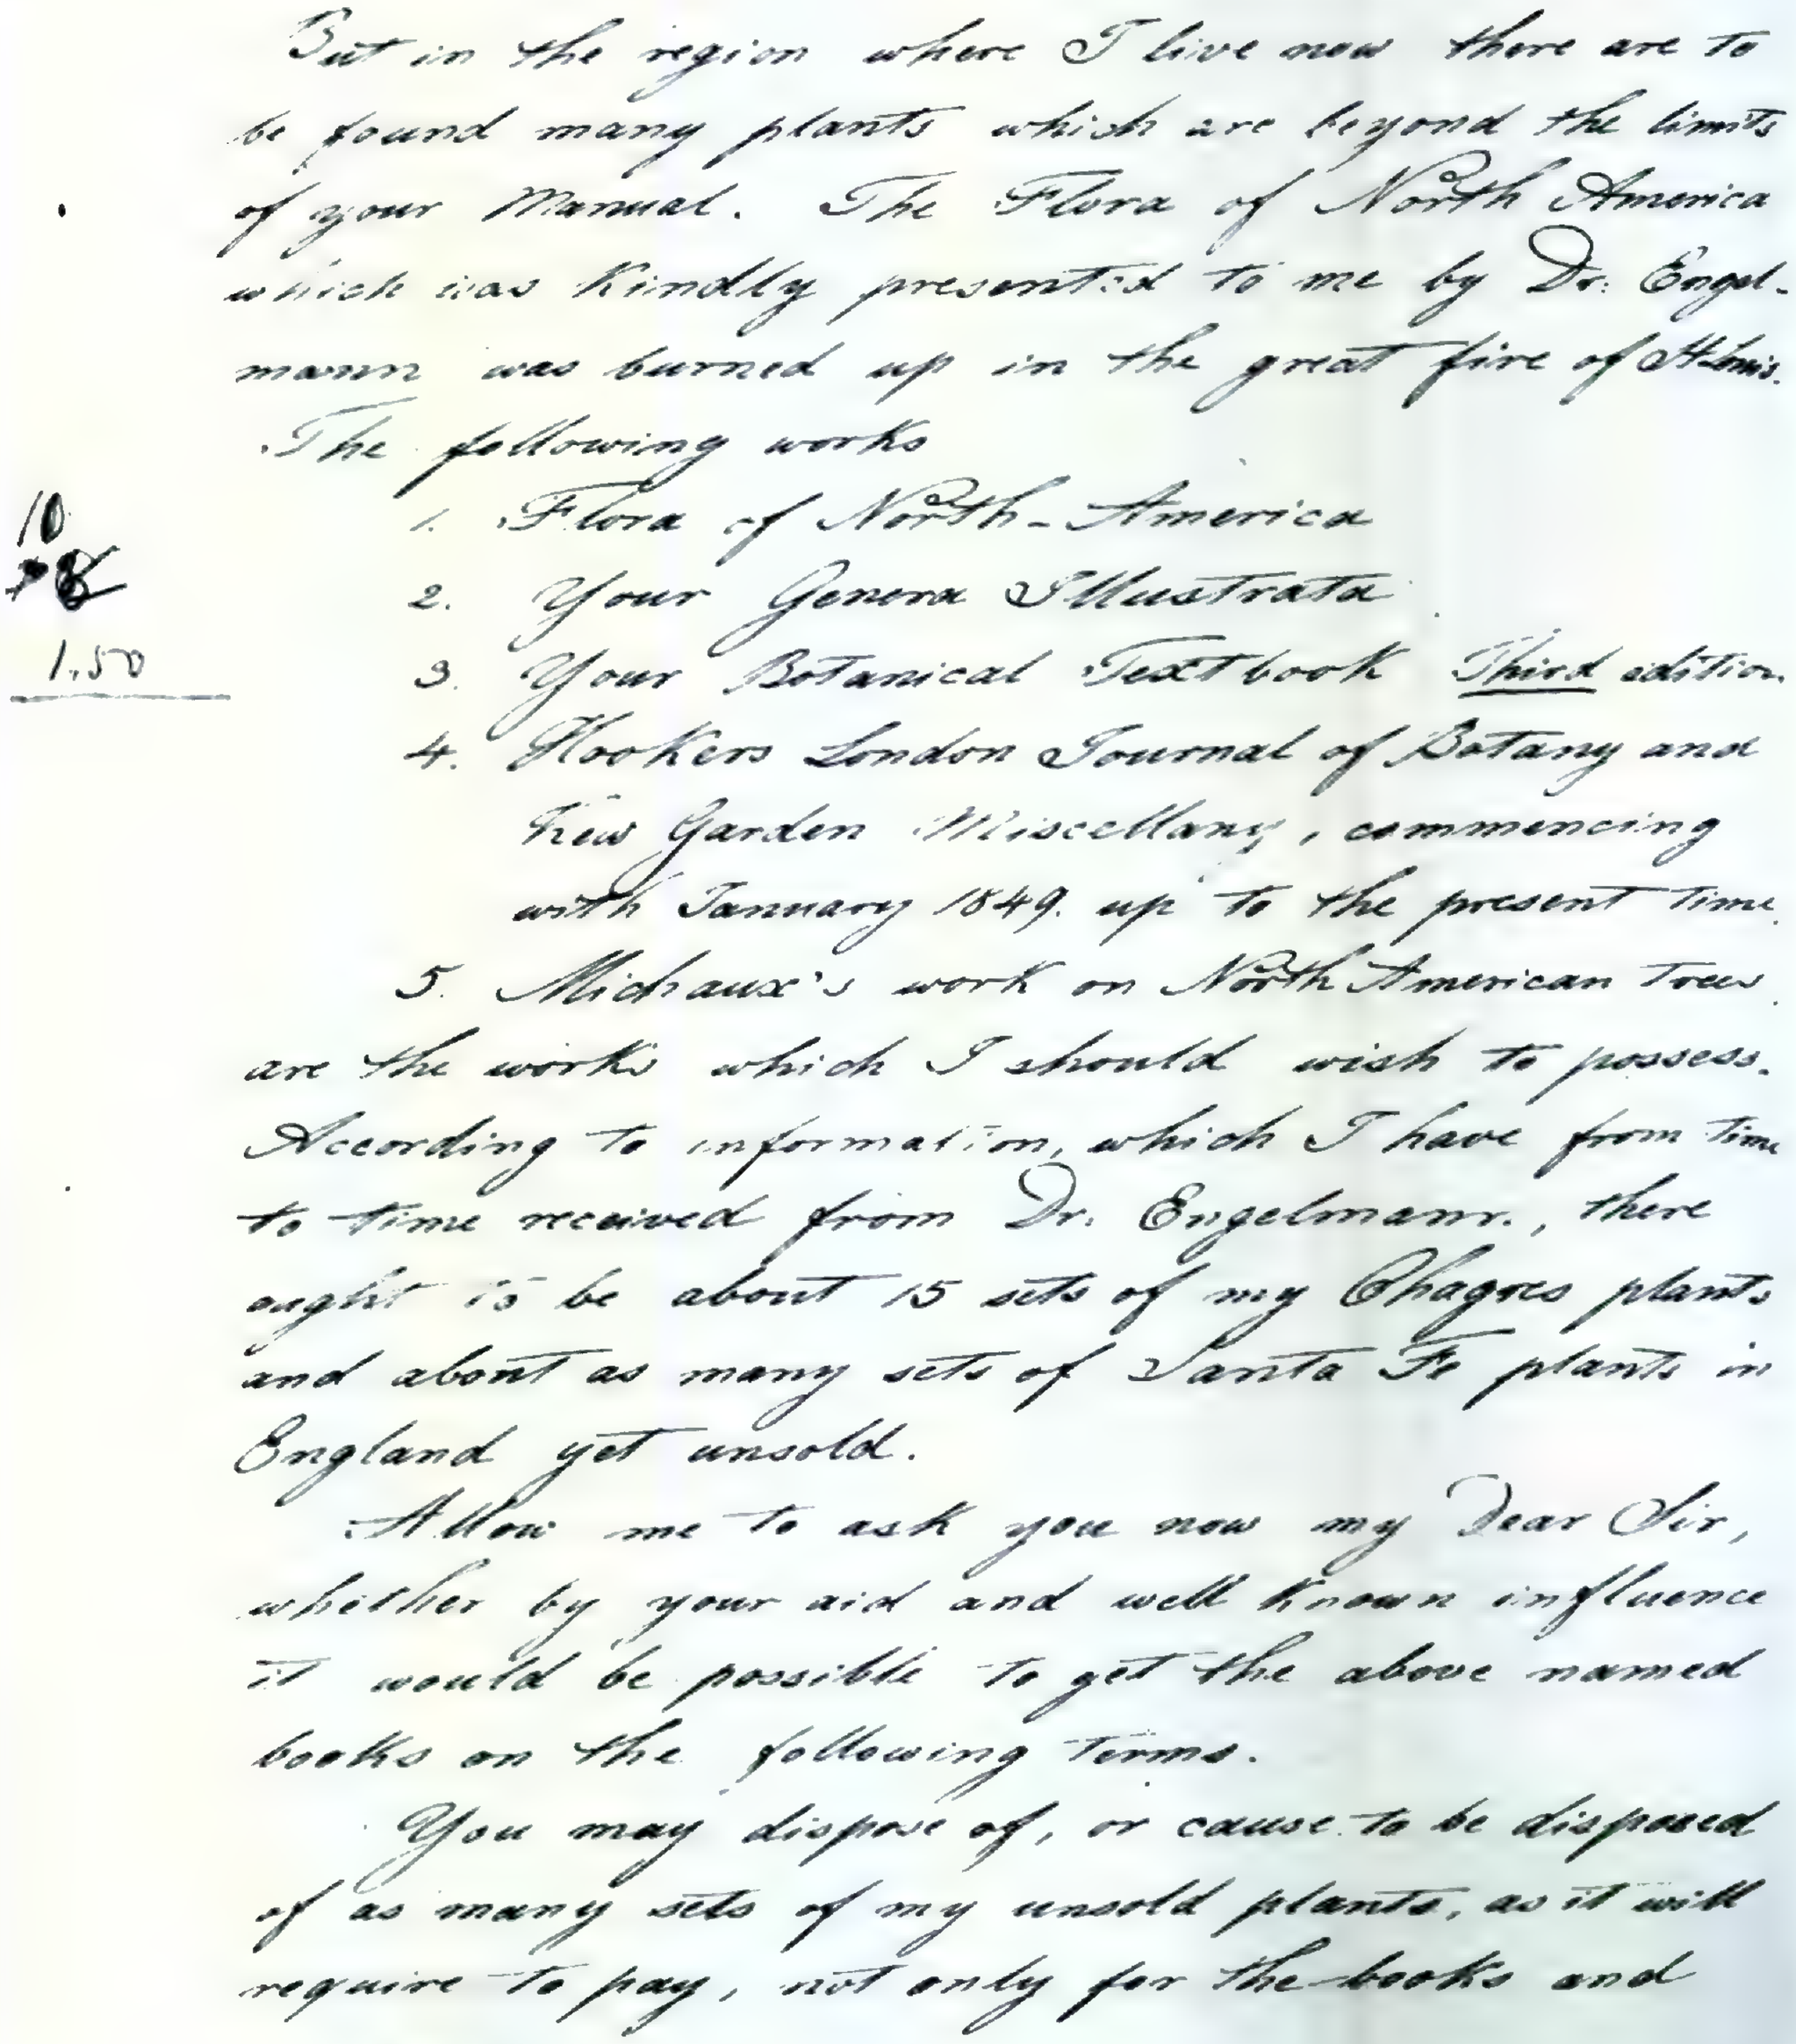
Professor Asa Gray M.D.
Harvard University.

Dear Sir

The interference of the Memphis Gas Company with my business, although it has somewhat unsettled my aims and thrown me off the steady track which I thought I was on, has at the same time given me a little more leisure, and I have once more turned my attention to surrounding vegitation. If I should make Memphis my abiding-place, I should consider it my pleasing task to investigate thoroughly and study as much as possible all the species of plants that grow within 5 or 10 miles around Memphis. But I am at present very poorly supplied with botanical works. All the books I have on botany are: Your botanical Textbook, second edition and your Manual of Botany of the Northern United States 1848. If I was living in the Northern States, these two most excellent little volumes would be sufficient for me to recognize all the plants growing there.

FIGURE 2. Letter by Augustus Fendler to Asa Gray (Memphis, Tennessee, July 13, 1853). Missouri Botanical Garden archives.

1850, and prospered there for four years in the gas-lamp business (Stieber & Lange, 1986). In 1853, when the lamp-lighting business in Memphis faltered, he was eager for a change of pace and wanted to resume collecting plants. He wrote to Gray on 11 August 1853 about his collecting plans: "My principal object in going to Caracas is: to go into a business again, by which I can support myself. But I hope I shall have plenty of leisure to make botanical collections besides. If I collect again I shall aim to make the sets as large and complete as possible. Do you think 15 sets, each containing from 1,000–1,500 species of plants collected about Caracas could meet with a ready sale?" On 15 August 1853, he wrote Engelmann that he wished to move to a town near Caracas because "In a city with a population of 70,000 I believe to be able to find more security than here,



But in the region where I live now there are to be found many plants which are beyond the limits of your Manual. The Flora of North America which was kindly presented to me by Dr. Engelmann was burned up in the great fire of St. Louis. The following works

1. Flora of North-America
2. Your Genera Illustrata
3. Your Botanical Textbook Third edition.
4. Hookers London Journal of Botany and Kew Garden Miscellany, commencing with January 1849 up to the present time.

5. Michaux's work on North American Trees.

are the works which I should wish to possess. According to information, which I have from time to time received from Dr. Engelmann., there ought is be about 15 sets of my Chagres plants and about as many sets of Santa Fe plants in England yet unsold.

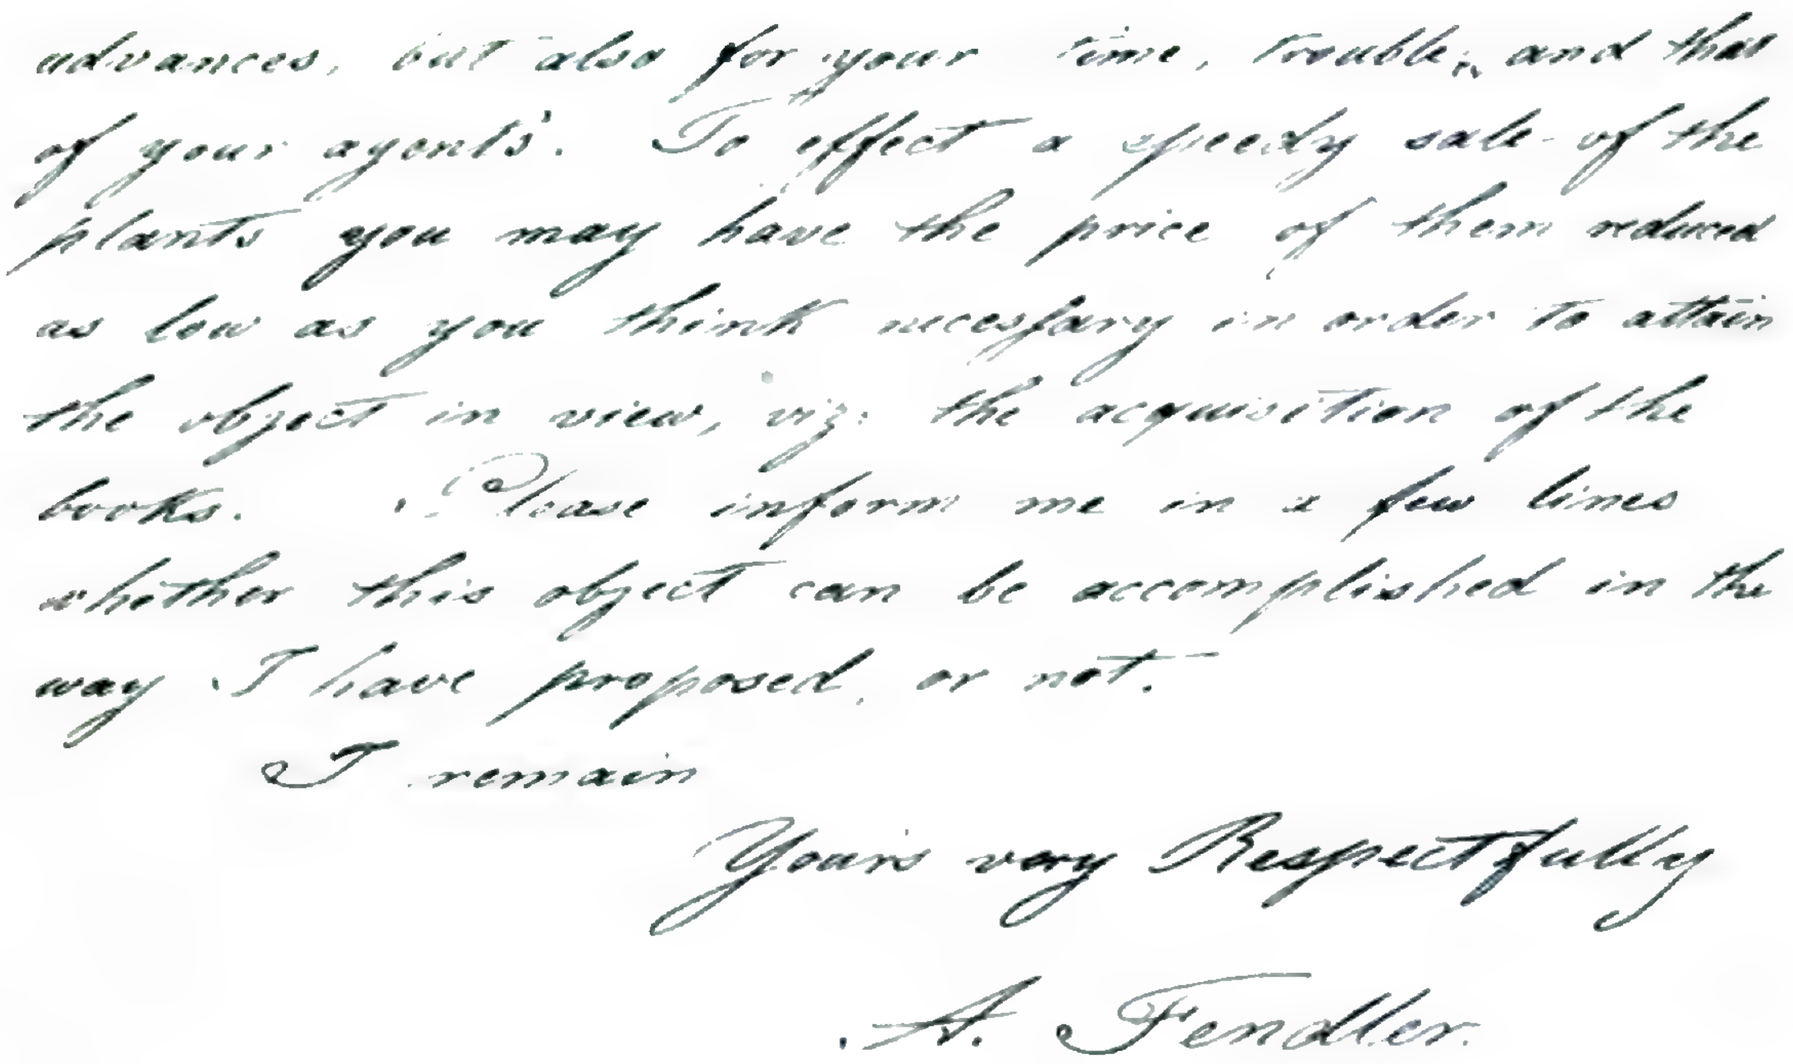
Allow me to ask you now my Dear Sir, whether by your aid and well known influence it would be possible to get the above named books on the following terms.

You may dispose of, or cause to be disposed of as many sets of my unsold plants, as it will require to pay, not only for the books and

FIGURE 2. Continued.

and secondly, because I believe I shall have a better climate there. Then also, the wish to live again in a mountain valley and to be in the vicinity of a rich mountain flora! without having the difficulties of long and difficult communication as I found in Santa Fe."

On the 24th of December 1853, Fendler sailed for Venezuela from New York harbor, accompanied by his chronically ill brother. They arrived in La Guaira, Venezuela, on 21 January 1854. In his day, it took five hours to reach Caracas from the coast. Upon arriving, he commenced collecting plants in the vicinity. Prompted by the high cost of living in Caracas, he went up to Colonia Tovar after only six weeks. After reaching the settlement, he wrote to Gray on 16 December 1854: "The base of the valley is 5,600 ft. above the sea, and some of the surrounding mountains about 2,000



advances, but also for your time, trouble, and that of your agents'. To effect a speedy sale of the plants you may have the price of them reduced as low as you think necessary in order to attain the object in view, viz: the acquisition of the books. Please inform me in a few lines whether this object can be accomplished in the way I have proposed, or not.

I remain

Yours very Respectfully

A. Fendler.

FIGURE 2. Continued.

feet higher . . . . The road from Caracas leads at first along a small river, which is very rapid and has to be crossed 42 times. The valley in which this river flows becomes at last very narrow and the road turns off to the left ascending a high mountain, from the tip of which it leads on in a westerly course along the very summit of the principal mountain range, through the deep shades of the primitive forest and down the valley of the Colony."

While at Colonia Tovar, Fendler also corresponded with Joseph Henry of the Smithsonian Institution, who published Fendler's letters and meteorological observations in the *Annual Report of the Board of Regents of the Smithsonian Institution*. Fendler was an ardent amateur meteorologist and in Venezuela traveled with a barometer, rain gauge, and thermometer. From his correspondence with Gray, Fendler provided a very rich description of Colonia Tovar (Fendler, 1857): "The valley in which Colonia Tovar is situated was, so late as December, 1841, a perfect wilderness, covered with primitive forest. Not even the existence of this valley was known fifteen years ago, neither to the government nor to its owner, although it is only thirty-five miles west of Caracas, the capital of Venezuela, and in a straight line cannot be more than twelve miles from the sea. And when an attempt was made to explore this region not even a guide could be found for the small exploring party of fifteen men, headed by Colonel Codazzi, a skillful officer and compiler of the new map of Venezuela. When this party at last succeeded in crossing this region and reaching the sea-shore, they thought they had achieved a most extraordinary thing, (to cross a distance of twelve miles in six days;) and after they had returned to their homes none of them had a desire to do the feat over again. This was a party of natives. And when, at a later period, after the establishment of the colony, another skillful engineer found, with a party of colonists, his way to the opposite port of the sea-shore, the party did not venture to go back the same route, but rather chose the way by sea to Laguayra, from there to Caracas and back to the colony, a very circuitous route certainly. Such is the nature of this mountain region, with its precipices, waterfalls, deep ravines, and its dense, almost impenetrable primeval forests."

Shortly after arriving in Colonia Tovar, Fendler bought a small farm in 1854 for 47 dollars. He described his new home in his letter to Gray of 16 December 1854: "My cottage stands on a small hill which is projecting from the sloping side of a mountain overlooking the greater part of the Colony. On the slopes of this little hill we have made terraces planted with *Musa sapientum*, with apple trees, Palms (*Oenocarpus utilis*), and stately tree ferns 14 feet high. Near the brown polished stem of the Palm the clear arch of a fountain (9 feet high) glitters in the tropical sun sending unceasingly its sparkling little stream to the top of the young

Palm. This fountain I made in a few days without outlay of money. Two pieces of the trunk of *Ceroxylon andicola* served as pipes." Fendler clearly enjoyed Colonia Tovar: "A visitor who never before lived in a valley like this finds here many peculiarities of vegetation, surface and climate which make him feel that he is not far off the land of perpetual peace; for he has entered the happy region of the ferns, the 'tierra templada de los helechos.' There is no scorching summer's heat, no fearful winter's cold, neither tornados to devastate the country nor gales to blind the inhabitants with sand and dust or penetrate their clothes and flesh with piercing frost" [Fendler to Gray, 16 December 1854]. His years in the village were the most enjoyable time of his life, and later letters indicate that he very much would have liked to return there [Fendler to Engelmann, 20 July 1882, Trinidad].

During his first year at Colonia Tovar, Fendler devoted much of his time to plant collecting. He wrote to Professor Henry: "In collecting botanical specimens, I have penetrated, without companion, the wilderness around in different directions, also that on the other side of the principal mountain range towards the sea, and can testify to the difficulties and hardships which are met with in exploring such a country . . . . In these woods, where the rays of the sun never touch the ground, there it is where moisture and a cool temperature reign forever. The trunk of every tree and its branches are covered with Ferns, Lycopodiaceae, Mosses, Hepaticae, Lichens, Orchids, Bromeliads, Araceae and besides Piperacae with many exogenous plants too numerous to mention" (Fendler, 1857).

Fendler wrote in detail to Gray, who had offered to enlist subscribers for his sets of plants. "I have already 8 boxes full of dried plants. The most attention I have hitherto paid to ferns of which I have 255 species, most of them complete; other plants I have not yet enumerated. For the last four or five weeks I have been employed with arranging my collections but have not yet finished. The fine dry weather which is now approaching urges me again to renewed activity in the field. The woods here are very dense and impenetrable without a sabre. The neighboring country is much diversified" [Fendler to Gray, 16 December 1854].

"Of Palms I have collected 6 species, of which 5 grow in the colony. Tree ferns 9 or 10 species. Cruciferae and Umbelliferae are represented only by 2 or 3 species. I do not intend to send plants until I can send something complete, and until I can ascertain the safest way to forward them" [Fendler to Gray, 16 December 1854]. Less than a year later, Fendler wrote: "Of flowering plants I have about 1,850 species, although my search after these may be called but a superficial one. I think from 800–1,000 more species might be collected and of ferns perhaps from 80–100 more" [Fendler to Gray, 25 November 1855]. In addition to ferns and angiosperms, Fendler collected fungi for M. A. Curtis, a mycologist in the Carolinas, lichens for Professor E. Tuckerman, a lichenologist at Amherst College, and mosses for William Starling Sullivant, a distinguished American bryologist in Ohio.

In 1857, after collecting in Colonia Tovar for over two years, Fendler found it increasingly difficult to find novel species. "In coming to a new country it is at first comparatively easy to make a living by collecting plants; for the collector can make use of all the different species that meet his eye, and can carry them home without the aid of other hired persons or beasts of burden. But after he has explored the neighborhood and is obliged to make extensive excursions of from 8–14 days or 3 weeks, the case is different, and he soon finds that his earnings do not come up to his expenses" [Fendler to Gray, 1 July 1857].

After collecting thoroughly around Colonia Tovar, Fendler took longer excursions crossing "the principal mountain chain in three different places. One from Maracai to Columbia [Puerto Colombia] to the very margin of the sea; the other from Valencia to San Estevan within 3 miles of Puerto Cabello; the third from Petaquire to within a few miles of the sea-shore. The two first regions are West, the third one East of Colonia Tovar. Besides these I have made a number of minor excursions into the neighboring valleys" [Fendler to Gray, 1 July 1857]. During these long excursions he reflected: "The more I attempt to explore these regions the more am I convinced, that a great deal remains yet to be done with regard to discovering and making known the plants of this country. These extensive ranges of mountains with their innumerable recesses and deep ravines, covered with the densest growth of primeval forest uninterrupted for more than 150 miles from East to West, have been in most places never been traversed by civilized men. When standing on some high mountain-peak and looking over a part of this territory, it needs no great power of imagination to be filled with a longing and an ardent desire to embark in enterprises even of the most perilous kinds, in order to penetrate the unknown abysses and to bring to light the hidden treasures of vegetation. And when in such moments I compare my strength and my fast waning pecuniary means, which forbid to hire

a companion to help me carry the burden, then I feel somewhat akin to depression of mind which prompts me to leave the spot and retrace my steps homewards."

Because Fendler viewed plant collecting as a business, he was very concerned with the marketability of his specimens, which were valued according to their origin, rarity, and completeness of identifications. Thus Fendler wished to have his plant collections be as rare as possible, as well as to have them determined. He was concerned that Karl Moritz, who had been living in Colonia Tovar for over ten years, would begin again to collect plants in his territory. "The present letter is chiefly written to make you acquainted with my intentions of sending the collections as soon as possible, that you may be enabled to correspond or to publish something to that account and secure me from 10–13 subscribers in time, because Mr. Moritz, who is still here has sometime ago commenced again to collect ferns, which he intends to send at an early date to Germany (I think to Berlin). I have seen Moritz's own set of his former collections when he used to travel about the greater part of Venezuela viz: the Orinoco, the mountains of Merida, Cumana, Caripe and a great many other regions; but the number of all his species of ferns will hardly exceed 250 or 260, while I have already 314, of which at least 290 are collected at the Colony or from 4–8 miles around it. There are several regions not far-off, where I never yet have been and which promise a very rich harvest of new species. I think I could augment the number of species considerably and discover many more new ones if I am sure that they find a market on which I may rely. I am therefore anxious to secure subscribers for them; so that I need not fear competition and then I shall go at it with renewed vigour; and if my life and health be spared I think of bringing together a rather complete representation of the vegetation of this and other parts of Venezuela. When I came here, Moritz seemed rather surprised that I should go at collecting plants in a place which he thought of being thoroughly ransacked, and he said that it would be a hard matter to find any new species. He seems however to have altered his opinion in this respect, after I had been in the field for some time; for I showed him many a plant which was new to him" [Fendler to Gray, 25 November 1855]. Fendler's Venezuelan collections surpass Moritz's in quantity and quality (J. A. Steyermark, pers. comm.; A. R. Smith, pers. comm.).

Plant collecting, however, was not profitable enough for Fendler to support himself and his invalid brother. "Whenever I was engaged in scientific pursuits for any length of time I was soon obliged to go to work at some other more profitable business, although that business might not be in accordance with my inclinations. And now I find again that the little capital, which I had earned at Memphis during three years by distilling camphene, is rapidly vanishing, notwithstanding the most frugal mode of living. I am therefore under necessity to try my hand for a while at something else beside collecting plants, and have already commenced to make experiments in brewing beer and making brandy; and shall be obliged (with regret do I say it), to spend most of my time behind the still . . . . By no means do I wish by the preceeding lines to convey to you the idea, that I am discouraged or that I have given up collecting plants. As long as strength and life and a few spare dollars remain with me I shall continue to do all I can for my favorite pursuit; and even now, whenever time and circumstances allow me to do so, I shall do it with the same zeal as I have done heretofore" [Fendler to Gray, 1 July 1857].

Fendler's Collections

In Venezuela Fendler collected under two number series, one for the ferns beginning at no. 1 and ending at no. 500, and one for flowering plants, numbers 1–2,630. Sets of Fendler's Venezuela plants were purchased by the following people and institutions (the number before the name indicates which set went to that recipient). (2) Hooker (K), (3) Grisebach (GOET), (4) A. Gray (GH), (5) Engelmann (MO), (6) Short (PH), (7) Charles Wyville Thomson (E), (8) Boissier (G), (9) De Candolle (G), (10) Oxford herbarium (OXF), (11) Harvey (TCD), (12) Delessert (G), (13) Martius (BR), (17) Eaton (YU), (18) Miss Elizabeth Morriss (?PHA), (21) Eaton (YU). It is not known whether sets 14–16 were sold at a later date, or whether they remained at GH. Sets 2–13 included ferns and phanerogams; sets 17–23 consisted only of ferns. The first and most complete set was retained by Fendler at first. Later he sold this first set of angiosperms to Gray. "My full set of Venezuelan plants contained over twice as many species as set No. 4, and therefore I hope that by the addition of those plants your herbarium would gain something. I would rather see them incorporated with your herbarium than with that of anyone else. The naming of the price of the lot I leave to you as you can judge best of their value, and I know that I am in good hands when I am in yours" [Fendler to Gray, 28 October

FIGURE 3. Map of the localities in northern Venezuela where A. Fendler collected in 1854–1858.

1863, St. Louis]. Ten cents per sheet was the usual asking price, although it was slightly higher for the orchids since they were often unicates.

At times Fendler felt he was not justly compensated for his specimens. For example, Lindley thought the price too high. "If Dr. Lindley was advised to pay but £2 per 100 for my Orchidae, then I will ask nothing more, and he shall be very welcome to them if he finds them to be worth that much. But if on the contrary he finds that the greater part of them, from being common things, are of no use to him, which I am inclined to infer from his letter, then I should be very sorry indeed that I ever offered them to him. To me that would be at least objects of remembrance of the amount of labor, bestowed upon, and perhaps of an over-animated enthusiasm in searching for them" [Fendler to Gray, 27 March 1859, St. Louis].

FENDLER'S FIELD NOTEBOOK

In 1859, Fendler sent Gray the field notes for his Venezuelan plants, retaining the information only on his personal set of specimens (set No. 1) [Fendler to Gray, 15 December 1859, St. Louis]. The field notes contain all dates and localities from which a particular species was collected, as well as elevation and notes about habit. Fendler numbered his plant collections according to the classification schemes presented in Gray's *Botany of the Northern United States* and Lindley's *Vegetable Kingdom* rather than the order in which they were collected, as is usually done today.

To obtain more complete sets of specimens, which could then be sold at a higher price, Fendler often applied the same number to specimens he believed to be the same species but were from widely distant localities. Fendler also attributed to the same collection number specimens collected on as many as five different dates. This was a common practice among professional plant collectors, particularly those working with Gray (Ewan, 1969), and a source of problems for plant systematists. The *International Code of Botanical Nomenclature* (Burdet et al., 1983) states that an "isotype is any duplicate (part of a single gathering made by a collector at one time) of the holotype." Since Fendler did not indicate on his specimens what specific date a particular sheet was collected, technically no isotypes can be designated. Of the 225 names in this list, 66 were collected on more than one date. Few taxonomists have previously been aware of this problem with the Fendler Venezuelan collections.

LOCALITIES

Almost all of Fendler's Venezuelan specimens bear blue labels imprinted at the top with "Plantae Venezuelanae" and "Prope coloniam Tovar legit

TABLE 1. Localities used in Fendler's angiosperm list.

	State	Latitude	Longitude	Approximate Elevation in Meters
Agua Blanca = Quebrada Agua Blanca	Aragua	9°54′N	69°22′W	
Biscaina	Aragua	10°20′N	67°15′W	1,000
Campanero	Carabobo	10°26′N	68°01′W	150
Caracas	D.F.	10°30′N	66°55′W	914
Cariaca = Carayaca	D.F.	10°32′N	67°07′W	800
Chichiribichi = Chichiriviche	D.F.	10°33′N	67°14′W	0
Choroni	Aragua	10°29′N	67°37′W	0
Colombia = Puerto Colombia	Aragua	10°30′N	67°36′W	0
Colonia Tovar	Aragua	10°25′N	67°17′W	2,400
Consejo = El Consejo	Aragua	10°14′N	67°16′W	200
Cumbote = Cumboto	Aragua	10°24′N	66°26′W	70
Esmeralda	Aragua	10°25′N	67°36′W	200
Guacara	Carabobo	10°14′N	67°53′W	438
Güigüe	Carabobo	10°05′N	67°47′W	420
Hacienda Curisal (not located)				
La Guayra = La Guaira	D.F.	10°36′N	66°56′W	0
Lagunassa = Lagunazo	D.F.	10°25′N	67°10′W	2,000
Las Aguntas = Las Adjuntas	D.F.	10°26′N	67°01′W	900
La Victoria	Aragua	10°14′N	67°20′W	585
Macarao	D.F.	10°26′N	67°02′W	1,400
Maracai = Maracay	Aragua	10°15′N	67°36′W	445
Maya, Punta	Aragua	10°32′N	67°24′W	1,400
Petaquire	D.F.	10°32′N	67°05′W	1,600
Piedernales = Pedernales	Carabobo	10°03′N	67°43′W	500
Puerto Cabello	Carabobo	10°28′N	68°01′W	0
San Carlos River	Aragua	10°19′N	67°19′W	
San Estévan = San Esteban	Carabobo	10°26′N	68°01′W	200
San Joaquin	Carabobo	10°16′N	67°47′W	450
Turmero	Aragua	10°14′N	67°29′W	466
Tuy River	Aragua, Miranda			
Urvina = La Urbina	D.F.	10°27′N	67°14′W	1,400
Valencia	Carabobo	10°11′N	72°12′W	478

A. Fendler 1845–5" at the bottom. The collection number is usually on the label, although it occasionally is on a slip of paper attached to the plant. Apparently Gray had these labels printed as he did for Wright's Cuban collections. Only the first set of Fendler's specimens, now at GH, has any collection data on them. Although the labels indicate that the sets were collected near Colonia Tovar in the state of Aragua, they were in fact also collected in the state of Carabobo and in the Distrito Federal. Figure 3 maps the Fendler localities in northern Venezuela, and Table 1 presents a list of these localities.

TYPE LIST

Of Fendler's 2,630 Venezuelan angiosperm collections, this study located records of 225 that have been designated as types. Since only the first of the 20 sets has collection data, full localities from the notebook are given for these types. In the following annotated list of angiosperm types based on Fendler Venezuelan collections, the number in the parentheses refers to the number of dates listed in the notebook. The orchids, numbers 1,359–1,489 and 2,124–2,155, were not included in the notebook.

The species names listed in Appendix I were gleaned mostly from the *Flora de Venezuela* and the *Catálogo de La Flora Venezolana* (Pittier et al., 1945–1947), as well as with the help of several specialists (see Appendix I). The current accepted names are given when known to me. Herbaria data were gathered from the original descriptions, the TROPICOS data base at MO, the specialists listed in Appendix I, and the author's search through the

MO herbarium. Unfortunately, there is no record of the number of duplicates made of each collection number (although the number may be on the labels of set No. 1 at GH, as with the ferns (Smith & Todzia, 1989), and therefore there is no way to ascertain which specific specimens are at any one herbarium. Since GH received Fendler's first set of angiosperms, excluding the orchids which went to Lindley, there are probably specimens for all numbers there. However, only herbaria where a specimen is confirmed to be deposited are included in the list. Overall, Fendler's Venezuelan specimens are widely distributed in the United States and Europe. The following 18 herbaria are known to have some Fendler Venezuelan collections (Lanjouw & Stafleu, 1957; pers. obs.): AMES, BR, BUF, C, CM, F, G, G-DC, GH, GOET, K, MO, NY, OXF, P, PH, S, and US.

Appendix I

List of species with type specimens collected by A. Fendler in Venezuela (1854–1858). The collection dates listed by Fendler in his notebook are indicated in square brackets. If duplicates of a given collection number were made on a single date only, the exact date is given and is expressed as day/month/year; the year is between 1854 and 1858. All collection localities for a given collection number are furnished. Information enclosed in brackets comes directly from Fendler's notebook. The location of specimen(s), if known, is cited. In many cases, however, information from the literature did not record the place of deposition of the specimen seen, although in some cases it can be inferred. Specimens were searched for at MO and if not found in the herbarium were not cited. I thank the following people for help with specific plant groups: E. A. Christenson (Orchidaceae), T. B. Croat (Araceae), W. G. D'Arcy (Solanaceae), G. Davidse (Cyperaceae, Poaceae), B. Hammel (Cyclanthaceae), J. Kuijt (Loranthaceae), C. Luer (Orchidaceae), J. Steyermark (Rubiaceae), H. van der Werff (Lauraceae), J. Wurdack (Melastomataceae, Polygalaceae), and J. Zarucchi (Apocynaceae, Fabaceae).

ANNONACEAE

Rollinia fendleri R. E. Fries, Acta Horti Berg. 12: 152, tab. 15. 1934.
[Biscaina, 3,000 ft., 5/6/55], *Fendler 196* (holotype, K).

APIACEAE

Hydrocotyle venezuelensis Rose ex Mathias, Brittonia 2: 226. 1936.
[Colonia Tovar, 6,000 ft., 13/4/54], *Fendler 524* (holotype, M; isotypes, G, K).

APOCYNACEAE

Amblyanthera fendleri Muell. Arg., Linnaea 30: 417. 1859–1860.
[A few mi. SE of Colonia Tovar, 5,000 ft., 12/4/54, 6/7/54, 4/9/54], *Fendler 1032* (G-DC, photo at B, BR, F, K, MO).
= *Mandevilla fendleri* (Muell. Arg.) Woodson

Dipladenia fendleri Muell. Arg., Linnaea 30: 417. 1859–1860.
[A few mi. W of Colonia Tovar, 7,000 ft., 12/5/54], *Fendler 1030* (holotype, G-DC, photo at F; isotypes, B, BR, F, K, MO).

ARACEAE

Anthurium bredemeyeri Schott var. **elongata** Engl., Fl. Bras. 3: 80. 1878.
[Colonia Tovar, 6,000–7,000 ft., 25/5/54, 15/9/54, 15/10/54], *Fendler 1346* (lectotype, MO; isolectotype, K).
= *Anthurium bredemeyeri* Schott

Anthurium fendleri Schott, Prodr. Syst. Aroid. 468. 1860.
[Biscaina, 3,000 ft., 10/5/54], *Fendler 1343* (holotype, K; isotype, GH).

Anthurium nymphaeifolium K. Koch & C. Bouché var. **ovatum** Engl., Monogr. Phan. 2: 177. 1879.
[6–8 mi. SE of Colonia Tovar, 5,000–6,000 ft., 12/5/54, 28/7/54, 15/10/54], *Fendler 1336* (syntype, K).
= *Anthurium ornatum* Schott

Philodendron deviatum Schott, Bonplandia 7: 29. 1859.
[Biscaina, 3,000 ft., 10/5/55], *Fendler 1329* (holotype, K).

Philodendron effusilobum Croat, Aroideana 9: 99. 1986.
[Near San Estevan, 1,000 ft., 9/3/57], *Fendler 2573* (holotype, GH).

Philodendron fraternum Schott, Bonplandia 7: 29. 1859.
[Colonia Tovar, 6,000–6,500 ft., 16/8/54, 19/6/55, 3/7/55], *Fendler 1327* (holotype, K; isotypes, GH, US).

ARALIACEAE

Dendropanax fendleri Seemann, J. Bot. 2: 301. 1914.
[A few mi. S of Colonia Tovar, 16/4/55], *Fendler 529* (MO).

ASCLEPIADACEAE

Philibertia fendleri A. Gray, Proc. Amer. Acad. Arts 21: 395. 1886.
[La Victoria, 20/11/56], *Fendler 2119* (GH, MO).
= *Sarcostemma bilobum* Hook. & Arn. subsp. *lindeniana* (Decne.) Holm

ASTERACEAE

Clibadium parviceps S. F. Blake, Contr. U.S. Natl. Herb. 22: 598. 1924.
[Between Maracai and Choroni, 4,000 ft., 12/12/56; also between Petaquire and Cariaca, 4,000 ft., 12/2/58], *Fendler 1967* (holotype, GH; isotype, US).

Eupatorium neriifolium B. L. Robinson, Contr. Gray Herb. 65: 49. 1922.
[Colonia Tovar, 6,500 ft., 23/6/55], *Fendler 634* (GH, photo at F).

Eupatorium steetzii B. L. Robinson, Proc. Amer. Acad. Arts 55: 36. 1919.
[Colonia Tovar, 6,500 ft., 27/8/54], *Fendler 647* (holotype, GH).

Eupatorium tovarense B. L. Robinson, Proc. Amer. Acad. Arts 54: 259. 1918.
[Between Petaquire and the sea, 4,000 ft., 22/4/58], *Fendler 1947* (holotype, GH; isotype, MO).
= *Ayapana tovarensis* (B. L. Robinson) R. King & H. Robinson

Eupatorium xestolepis B. L. Robinson var. **xestolepis,** Proc. Amer. Acad. Arts 54: 261. 1918.
[Between Caracas and La Guayra; also a few mi. SE of Colonia Tovar, 7/5/55, 10/5/55, 16/8/55], *Fendler 638* (holotype, GH).

Hieracium tovarense Fries, Epicris. Hierac. 152. 1862.
[Around Colonia Tovar, 6,000–7,500 ft., 26/7/54, 7/5/55, 28/6/55, 23/8/55, 17/7/56], *Fendler 718* (G, photo at F).
= *Hieracium avilae* H.B.K.

Mikania gracilipes B. L. Robinson, Contr. Gray Herb. 61: 15. 1920.
[Between Valencia and Campanero, 5,000 ft., 27/2/57], *Fendler 2348* (holotype, GH; isotypes, MO, G, photo at F).

Mikania hexagona B. L. Robinson, Proc. Amer. Acad. Arts 47: 196. 1911.
[Tuy River below Colonia, 4,000 ft., 21/10/54], *Fendler 626* (holotype, GH, photo at F).

Mikania racemulosa Klatt, Abh. Naturf. Ges. Halle 15: 325. 1882.
[Colonia Tovar, 6,000–7,000 ft., 31/3/54, 28/6/55], *Fendler 625* (GH, MO, photo at F) syntype with *Schomburgk 480* (G).

Mikania vitrea B. L. Robinson, Contr. Gray Herb. 61: 22. 1920.
[Colonia Tovar, 6,500 ft., 24/5/57], *Fendler 2349* (holotype, GH; isotype, G, photo at F).
= *Mikania hookeriana* DC. var. *crassicaulis* Steyerm.

Piptocarpha sprucei Baker, Fl. Bras. 6(2): 129. 1873.
[Between Maracai and Choroni, 2,500 ft., 28/1/57], *Fendler 1957* (syntype).

Senecio cucullatus Klatt, Abh. Naturf. Ges. Halle 15: 331. 1882.
[Colonia Tovar, 6,500 ft., 24/8/55], *Fendler 702* (P, MO, photo at F).

Trichogonia rhadinocarpa B. L. Robinson, Proc. Amer. Acad. Arts 42: 36. 1906.
[Biscaina, 3,200 ft., 5/6/55], *Fendler 651* (GH).

BEGONIACEAE

Begonia fagopyroides Kunth & Bouché var. **fendleriana** A. DC., Prodr. 15(1): 289. 1864.
[A few mi. SE of Colonia Tovar, in ravines, 3,500 ft., 9/3/55, 7/5/55], *Fendler 513* (G-DC, K).

BROMELIACEAE

Aechmea cymoso-paniculata Baker, J. Bot. 17: 165. 1879.
[Between Petaquire and the sea, 3,000 ft., 9/2/57], *Fendler 2453* (holotype, K; isotype, MO).

Aechmea fendleri André ex Mez, Bromel. Andreanae 13. 1889.
[Between Petaquire and Colonia Tovar, 7,000 ft., 11/2/57], *Fendler 2454* (holotype, K; isotype, GH).

Bilbergia filicaulis Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 13. 1865.
[Between Valencia and Campanero, 500 ft., 7/3/57], *Fendler 2452* (holotype, GOET, photo US).
= *Aechmea filicaulis* (Griseb.) Mez

Pitcairnia fendleri Mez, Monogr. Phan. 9: 387. 1896.
[Between Caracas and La Guayra, 1,500 ft., 16/8/55], *Fendler 1550* (holotype, GOET, photo US).

Tillandsia acorifolia Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 19. 1865.
[Seaside of mountains N of Colonia Tovar, 6,000 ft.,

22/1/56], *Fendler 1771* (holotype, GOET).
= *Guzmania acorifolia* (Griseb.) Mez

Tillandsia aurantiaca Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 16. 1865.
[Between Petaquire and Cariaca, 4,500 ft., 12/2/58], *Fendler 2575* (holotype, GOET, photo US).
= *Tillandsia tetrantha* Ruíz Lopez & Pavón var. *aurantiaca* (Griseb.) Lyman B. Smith

Tillandsia caribaea Lyman B. Smith, Proc. Amer. Acad. Arts 70: 155. 1935.
[High mountains near Colonia Tovar, 6,000 ft., 14/2/55, 17/6/55], *Fendler 1523* (holotype, GOET, photo US).

Tillandsia compacta Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 18. 1865.
[A few mi. SE of Colonia Tovar, 6,000 ft., 25/5/54, 21/6/54], *Fendler 1508* (holotype, GOET; isotype, K).
= *Tillandsia compacta* Griseb. var. *compacta*

Tillandsia excelsa Griseb. var. **latifolia** Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 17. 1865.
[A few mi. SE of Colonia Tovar, 6,000 ft., 7/5/55], *Fendler 1516* (GH, GOET).
= *Tillandsia fendleri* Griseb. var. *fendleri*

Tillandsia fendleri Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 17. 1865.
[Between Caracas and Colonia Tovar, 6,000 ft., 7/5/55], *Fendler 1515* (holotype, GOET, photo US).
= *Tillandsia fendleri* Griseb. var. *fendleri*

Tillandsia grisebachiana Baker, J. Bot. 26: 143. 1888.
[Colonia Tovar, 6,500 ft., 25/5/54, 21/6/54], *Fendler 1509* (GH).

Tillandsia incurva Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 15. 1865.
[6 mi. SE of Colonia Tovar, 6,000 ft., 28/8/54, 7/5/55], *Fendler 1524* (holotype, GOET; isotype, GH).
= *Vriesea incurva* (Griseb.) Read

Tillandsia laxa Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 18. 1865.
[Between Maracai and Choroni, 3,000 ft., 29/1/57], *Fendler 2166* p.p. (holotype, GOET, photo US).
= *Vriesia laxa* (Griseb.) Mez

Tillandsia lineatifolia Mez, Monogr. Phan. 9: 686. 1896.
[Between Petaquire and the sea, 3,500 ft., 2/9/57], *Fendler 2447* (GOET, photo GH).
= *Tillandsia anceps* G. Lodd.

Tillandsia longibracteata Baker, J. Bot. 26: 81. 1888.
[Between Petaquire and the sea, 5,000 ft., 9/2/57], *Fendler 2449* (syntype).
= *Vriesea splendens* (Brongn.) Lemaire var. *formosa* Sur. ex Witte

Tillandsia longifolia Baker, Handb. Bromel. 185. 1889.
[A few mi. SE of Colonia Tovar, between rocks, 6,000–6,700 m, 7/5/55, 14/5/55], *Fendler 1522.*

Tillandsia mucronata Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 20. 1865.
[Between Maracai and Choroni, 6,500 ft., 29/1/57], *Fendler 2159* (holotype, GOET, photo US; isotype, K).
= *Guzmania mucronata* (Griseb.) Mez

Tillandsia myriantha Baker, J. Bot. 25: 242. 1887.
[7 mi. SE of Colonia Tovar, 5,000 ft., 14/5/55], *Fendler 1530* (holotype, K; isotype, GOET).

Tillandsia pleiosticha Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 19. 1865.
[High mountains E of Colonia Tovar, 7,000 ft., 11/7/54, 19/3/55], *Fendler 1514* (holotype, GOET, photo US; isotype, K).
= *Guzmania pleiosticha* (Griseb.) Mez

Tillandsia robusta Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 15. 1865.
[Maya, 4,000 ft., 23/6/55], *Fendler 1525.*
= *Vriesea robusta* (Griseb.) Lyman B. Smith

Tillandsia tovarensis Mez, Monogr. Phan. 9: 769. 1896.
[Between Petaquire and Colonia Tovar, 26/10/57], *Fendler 2446* (holotype, GOET, photo US).

Tillandsia ventricosa Griseb., Nachr. Königl. Ges. Wis. Georg-Augusts-Univ. 1864: 19. 1865.
[High mountains E of Colonia Tovar, 7,000 ft., 7/5/55], *Fendler 1517* (holotype, GOET; isotypes, GH, K).
= *Guzmania ventricosa* (Griseb.) Mez

BURSERACEAE

Protium laxiflorum Engl. var. **fendleri** Engl., Monogr. Phan. 4: 67. 1883.
[Large tree yielding a resin called "Taca mahac," flowers green. Colonia Tovar, 6,400 ft., 22/4/54, 19/9/55], *Fendler 177* (holotype, G, photo F).

CAPPARACEAE

Cleome moritziana Klotzsch ex Eichler, Fl. Bras. 13(1): 250. 1841.
[A few mi. S of Colonia Tovar, 4,000 ft., 18/5/55], *Fendler 27* (lectotype, F?).

CELASTRACEAE

Maytenus fendleri Briq., Annuaire Conserv. Jard. Bot. Genève 20: 360. 1919.
[A few mi. SW of Colonia Tovar, 6,500 ft., 28/6/55], *Fendler 215* (F, G).

CHLORANTHACEAE

Hedyosmum pseudoandromeda Solms-Laub., Prodr. 16(1): 481. 1869.
[Colonia Tovar, 6,500 ft., 26/7/56, 21/8/56, 4/9/56], *Fendler 1127* (lectotype G, photos GH, MO, NY; isolectotypes, BR, G, GH, MO, NY, S, US).

COMMELINACEAE

Phaeosphaerion efoveolatum C. B. Clarke, Monogr. Phan. 3: 136. 1881.
[Between Caracas and Colonia Tovar, 6,000 ft., 23/8/55], *Fendler 1555* (holotype, G).

CONVOLVULACEAE

Ipomoea alatipes Hook., Bot. Mag. pl. 5330. 1862.
[Between Biscaina and La Victoria, 2,000 ft., 8/9/56], *Fendler 2084* (syntype, K).
= *Operculina alatipes* (Hook.) House

Ipomoea fendleriana Kuntze, Rev. Gen. Pl. 2: 444. 1891.
[La Victoria, 2,000 ft., 21/11/56], *Fendler 2083.*
= *Ipomoea calantha* Griseb.

Ipomoea fruticosa Kuntze, Revis. Gen. Pl. 2: 444. 1891.
[A few mi. W of Colonia Tovar, 7,000 ft., 17/4/55, 3/2/58], *Fendler 941.*

[Between Turmero and Agua Blanca, 1,800 ft., 30/1/57, 30/1/58], *Fendler 2082.*

CUCURBITACEAE

Echinocystis polycarpa Cogn., Mém. Couronnés Autres Mém. Acad. Roy. Sci. Belgique 28: 90. 1878.
[Caracas, 3,000 ft., 23/2/54], *Fendler 503* (G, photo at F).

Edmondia spectabilis Cogn., Monogr. Phan. 3: 420. 1881.
[Colonia Tovar, 6,500 ft., 5/5/54, 6/3/55], *Fendler 489* (G, photo at F).

Gurania wagneriana Cogn., Mém. Couronnés Autres Mém. Acad. Roy. Sci. Belgique 28: 25. 1877.
[A few mi. S of Colonia Tovar, 3,000–4,000 ft., no date], *Fendler 490* (G, photo at F).

Sicyos macrocarpus Cogn., Monogr. Phan. 3: 893. 1881.
[Near Güigüe, 2,000 ft., 25/1/55], *Fendler 502* (syntype, K).
= *Anomalosicyos macrocarpus* (Cogn.) H. Gentry

CYCLANTHACEAE

Asplundia fendleri Harling, Acta Horti Berg. 18: 221. 1958.
[In and near Colonia Tovar, 6,000–6,500 ft., 7/7/54, 23/8/56], *Fendler 1348* (holotype, K; isotype, GH).

Evodianthus funifer (Poit.) Lindman subsp. **fendlerianus** Harling, Acta Horti Berg. 18: 274. 1958.
[Between Petaquire and the sea, 3,500 ft., 22/4/58], *Fendler 2617* (holotype, K; isotypes, GH, GOET).

CYPERACEAE

Rhynchospora rudis C. B. Clarke, Kew Bull. 8: 39. 1908.
[A few mi. W of Colonia Tovar, 7,000 ft., 28/8/54, 19/9/55, 19/7/56], *Fendler 1591* (holotype, K).

DIOSCOREACEAE

Dioscorea fendleri R. Knuth, Pflanzenr. 4, Fam. 43: 65. 1924.
No information in notebook. *Fendler 2171.*

ELAEOCARPACEAE

Sloanea fendleriana Benth., J. Linn. Soc. Bot. 5, suppl. 2: 70. 1861.
[Seaside of mountains between Maracai and Choroni, 3,000–4,000 ft., 26/10/56, 12/12/56], *Fendler 2489* (holotype, K).

EUPHORBIACEAE

Acalypha villosa Jacq. var. **intermedia** Muell. Arg., Linnaea 34: 8. 1865.
[La Victoria, 2,000 ft., 21/12/56], *Fendler 1825* (syntype, G-DC; isotype, MO).
[Near La Victoria, 2,500 ft., 14/11/56], *Fendler 2408* (syntype, G-DC).
= *Ricinocarpus villosus* (Jacq.) Kuntze var. *intermedius* (Muell. Arg.) Kuntze

Alchornea grandiflora Muell. Arg., Linnaea 34: 170. 1865.
[Colonia Tovar, 6,500 ft., 7/4/54, 13/4/54, *Fendler 1272* (G-DC, MO, photo F).
= *Ricinocarpus villosus* (Jacq.) Kuntze var. *intermedius* (Muell. Arg.) Kuntze

Euphorbia tovarensis Boiss., Prodr. 15(2): 59. 1862.
[Maya, 3,000 ft., 12/12/54], *Fendler 1191* (holotype, G; isotype, MO).

Excoecaria obtusiloba Muell. Arg., Linnaea 32: 125. 1865.
[Biscaina, 3,000 ft., 5/6/55], *Fendler 1230* (G-DC, photo F).

Mabea rubrivenium Poeppig & Endl.
[Colonia Tovar, 6,500 ft., 7/5/54, 16/6/55], *Fendler 1232.*

Pedilanthus fendleri Boiss., Prodr. 15(2): 5. 1862.
[Between Caracas and La Guayra, 1,000 ft., 16/8/55], *Fendler 1202* (G-DC, photo F).

Plukenetia penninervia Muell. Arg., Linnaea 34: 158. 1865.
[Near Biscaina, 3,000 ft., 1/2/57], *Fendler 2412* (holotype, G-DC, photo F).

Tragia fendleri Muell. Arg., Linnaea 34: 179. 1865–1866.
[Biscaina, 3,000 ft., 5/6/55], *Fendler 1208* (holotype, G-DC, photo F).

FABACEAE

Calliandra laxa var. **parvifolia** Benth., Trans. Linn. Soc. London 30(3): 551. 1875.
[Between La Victoria and Biscaina, 2,500 ft., 1/2/57], *Fendler 2255* (K).

Canavalia fendleri Piper, Contr. U.S. Natl. Herb. 20(14): 570. 1875.
[Biscaina, 7/9/55], *Fendler 248* (holotype, K; isotype, MO).

Cassia viciifolia Benth., Trans. Linn. Soc. London 27: 544. 1871.
[Between Turmero and La Victoria, 2,000 ft., 14/3/57], *Fendler 2230* (lectotype, K).
= *Senna viciifolia* (Benth.) Irwin & Barneby

Inga fendleriana Benth., Trans. Linn. Soc. London 30(3): 630. 1875.
[Valley of Macarao, 3,500 ft., 18/1/57], *Fendler 2259* (K).

Machaerium moritzianum Benth., J. Proc. Linn. Soc., Bot. 4(suppl.): 58. 1860.
[Valley of Macarao, 4,000 ft., 4/7/56], *Fendler 1750* (syntype, K).
[Near La Victoria, 2,200 ft., 21/11/56], *Fendler 1866* (syntype, K).

Machaerium tovarense Pittier, Contr. U.S. Natl. Herb. 20(3): 121. 1917.
[La Victoria, 2,000 ft., 14/11/56], *Fendler 1865* (holotype, GH; isotype, MO).

Mimosa tovarensis Benth., Trans. Linn. Soc. London 30(3): 407. 1875.
[Caracas, 3,500 ft., 13/2/54], *Fendler 344* (holotype, K; isotype, MO).

Moldenhawera mollis Benth., Fl. Bras. 15(2): 77. 1870.
[La Victoria, 2,000 ft., 21/11/56], *Fendler 1864* (K).

GENTIANACEAE

Symbolanthus magnificus Gilg, Engl. Bot. 22: 343. 1896.
[10 mi. SE of Colonia Tovar, 5,000–6,000 ft., 8/4/54, 19/6/54, 4/9/54], *Fendler 830* (B, MO, photo F).

= *Symbolanthus calygonus* (Ruíz Lopez & Pavón) Griseb.

GESNERIACEAE

Columnea fendleri Sprague, Kew Bull. 1912: 41. 1912.
[Between Petaquire and the sea, 5,000 ft., 9/2/57], *Fendler 2031* (probably K).
= *Columnea scandens* L. var. *fendleri* (Sprague) Wiehler

Monopyle leucantha Moritz ex Benth., Icon. Pl. 12: 87. 1876.
[Colonia Tovar, 5,800–6,200 ft., 31/2/54, 27/3/54, 10/5/55, 17/6/54, 29/8/54], *Fendler 794* (MO).

LAMIACEAE

Salvia tovariensis Briq., Annuaire Conserv. Jard. Bot. Genève 2: 130. 1898.
[Between Caracas and Maya, 3,200 ft., 12/2/54, 12/5/54], *Fendler 876* (G).

Stachys fendleri Briq., Annuaire Conserv. Jard. Bot. Genève 2: 115. 1898.
[Near Colonia Tovar, 6,500 ft., 31/2/54, 19/12/54, 20/6/55, 21/9/55], *Fendler 879* (G, MO, photo F).

LAURACEAE

Gymnobalanus fendleri Meissn., Prodr. 15(1): 142. 1864.
[Between Valencia and Campanero, 5,500 ft., 7/3/57], *Fendler 2395* (holotype, G-DC).
= *Ocotea fendleri* (Meissn.) Rohwer

Gymnobalanus latifolia Meissn., Prodr. 15(1): 141. 1864.
[Between Colonia Tovar and Petaquire, 5,000 ft., 19/2/55], *Fendler 1095* (G-DC, photo F).

Mespilodaphne vaginans Meissn., Prodr. 15(1): 104. 1864.
[Colonia Tovar, 6,000 ft., 21/6/54, 21/3/57], *Fendler 1098* (types, G-DC, photo F, G, K, MO, NY, US).
= *Ocotea vaginans* (Meissn.) Mez

Nectandra leucantha Nees & Martius var. **attenuata** Meissn., Prodr. 15(1): 151. 1864.
[La Victoria, 2,000 ft., 14/10/56], *Fendler 2393* (syntypes G, K, MO).

LECYTHIDACEAE

Eschweilera fendleriana Miers, Trans. Linn. Soc. 30: 250, t. 60, fig. 6. 1874. *Fendler s.n.* (K).
= *Lecythis fendleriana* (Miers) Kunth

LILIACEAE

Smilax scabriuscula H.B.K. var. **fendleri** A. DC., Monogr. Phan. 1: 143. 1878.
[Near Colonia Tovar, 6,000–7,000 ft., 19/6/54, 3/12/54, 16/9/55], *Fendler 1546* (G, MO, photo at F).

LOGANIACEAE

Strychnos fendleri Sprague & Sandw., Kew Bull. 1927: 129. 1927.
[La Victoria, 2,500 ft., 21/11/56], *Fendler 2314* (K).

LORANTHACEAE

Dendrophthora basiandra Kuijt, Wentia 6: 32. 1961.
[Colonia Tovar, 6,800 ft., 10/8/54], *Fendler 1104* (holotype, GH; isotypes, GH, K).

Dendropthora eichleriana Urban, Ber. Deutsch. Bot. Ges. 14: 287. 1896.
[Colonia Tovar, 6,800 ft., 14/2/55], *Fendler 1101* (holotype, K; isotypes, GH, K, MO, PH).

Phoradendron bilineatum Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 5. 1897.
[La Victoria, 2,000 ft., 21/1/56], *Fendler 1811.*

Phoradendron cuneifolium Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 5. 1897.
[Biscaina, 3,200 ft., 5/6/55], *Fendler 1115.*

Phoradendron fendlerianum Eichler, Fl. Bras. 5(2): 129. 1868.
[Colonia Tovar, 8/4/54, 10/5/54, 9/3/55], *Fendler 1102* (MO).

Phoradendron longipetiolatum Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 6. 1897.
[Colonia Tovar, 6,500 ft., 10/7/56], *Fendler 1762.*

Phoradendron ovalifolium Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 6. 1897.
[Biscaina, 3,500 ft., 10/5/55], *Fendler 1108.*

Phoradendron rigidum Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 7. 1897.
[Colonia Tovar, 6,500 ft., 1/6/55], *Fendler 1105.*

Phoradendron tovarense Urban, Bot. Jahrb. Syst. 23, Beibl. 57: 8. 1897.
[A few mi. SE of Colonia Tovar, 6,000 ft., 26/7/56], *Fendler 1761.*
= *Phoradendron dipterum* Eichler

Phoradendron tubulosum Urban, Eng. Bot. Jahrb. 23, Beibl. 57: 5. 1897.
[Biscaina, 3,200 ft., 7/9/55], *Fendler 1106* (syntype).

Phoradendron venezuelense Trel., Genus Phoradendron, 111. 1916.
[La Victoria, 2,000 ft., 21/11/56], *Fendler 1810* (holotype, K; isotype, GH).
= *Phoradendron quandrangulare* (H.B.K.) Krug & Urban

Stachyphyllum fendleri van Tiegh., Bull. Soc. France 42: 565. 1895.
[Colonia Tovar, 6,500 ft., 15/8/54, 24/10/55, 8/11/56], *Fendler 1125* (holotype, P; isotypes, GH, MO).
= *Antidaphne viscoidea* Poeppig & Endl.

MELASTOMATACEAE

Arthrostemma alatum Triana, Trans. Linn. Soc. London 28: 35. 1871.
[Near La Victoria, 2,000 ft., 21/11/56], *Fendler 1832* (G, MO, photo F).

Blakea grisebachii Cogn., Monogr. Phan. 7: 1071. 1891.
[Seaside of mountains, N of Agua Blanca, 4,000 ft., 30/1/58], *Fendler 2547* (syntypes, GH, GOET).

Blakea longibracteata Cogn., Monogr. Phan. 7: 1074. 1891.
[Between Petaquire and the seashore, 5,500 ft., 22/4/58], *Fendler 2593* (holotype, GOET).

Calophysa ? flexuosa Triana, Trans. Linn. Soc. London 28: 141. 1871.
[Between Petaquire and the sea, 4,000 ft., 9/2/57], *Fendler 2261.*
= *Clidemia flexuosa* (Triana) Cogn.

Clidemia ampla Cogn., Monogr. Phan. 7: 1023. 1891.
[Between Petaquire and the seashore, 5,500 ft., 22/4/58, *Fendler 2594* (syntypes, F, G, GH, GOET, K, MO).

Clidemia ciliata D. Don var. **grandifolia** Cogn., Monogr. Phan. 7: 1020. 1891.
[Between Maracai and Choroni, 3,000 ft., 24/1/57], *Fendler 436.*
= *Clidemia ciliata* D. Don var. *ciliata*

Clidemia fendleri Cogn., Monogr. Phan. 7: 1016. 1891.
[Mountains near Caracas, a few mi. SE of Colonia Tovar, 17/2/54, 7/5/55, 19/6/55, 3/7/55], *Fendler 438* (G, MO, photo F).

Clidemia grandifolia Cogn., Monogr. Phan. 7: 1018. 1891.
[Between Maracai and Choroni, 4,000 ft., 28/1/57], *Fendler 2263* (syntypes, G, MO).

Henriettella tovarensis Cogn., Monogr. Phan. 7: 1044. 1891.
[Near Colonia Tovar, 5,600 ft., 6/4/54, 22/9/55, 3/10/55], *Fendler 444* p.p. (G, photo F, MO).

Henriettella tovarensis Cogn. var. **angustifolia** Cogn., Monogr. Phan. 7: 1044. 1891.
[Near Colonia Tovar, 5,600 ft., 6/4/54, 22/9/55, 3/10/55], *Fendler 444* p.p. (syntype, G, photo F).

Heterotrichum glandulosum Cogn., Monogr. Phan. 7: 955. 1891.
[A few mi. SE of Colonia Tovar, 5,100 ft., 4/9/54, 3/7/55], *Fendler 432* (G, photo F).
= *Micronia araguensis* Wurdack

Heterotrichum lucidum Triana, Trans. Linn. Soc. London 28: 134. 1871.
[Colonia Tovar, 6,500 ft., 2/9/56], *Fendler 1845* (MO).

Leandra fendleri Cogn., Monogr. Phan. 7: 653. 1891.
[Near Colonia Tovar, 7,000 ft., 12/6/54, 3/12/54, 12/5/55, 27/8/55], *Fendler 439* (G, MO, photo F).
= *Leandra lindeniana* (Naud.) Cogn.

Meriania subumbellata Cogn., Monogr. Phan. 7: 430. 1891.
[Between Maracai and Choroni, 4,000 ft., 12/12/56, 29/1/57], *Fendler 1830.*

Miconia fendleriana Cogn., Monogr. Phan. 7: 822. 1891.
[Between Maracai and Choroni, 4,000 ft., 12/12/56], *Fendler 1835* (syntype, GOET).
[Between Maracai and Choroni, 6,000 ft., 12/12/56], *Fendler 1836* (syntype, GOET).

Miconia multinervulosa Cogn., Monogr. Phan. 7: 926. 1891.
[Near Colonia Tovar, 6,500 ft., 15/5/55, 23/8/56], *Fendler 415* (syntypes, G, photo F).
= *Miconia theaezans* (Bonpl.) Cogn.

Miconia resimoides Cogn., Monogr. Phan. 7: 926. 1891.
[Near Colonia Tovar, 6,500 ft., 15/5/55, 23/8/56], *Fendler 414* (G, MO, photo F).

Miconia rubens Naudin var. **latifolia** Cogn., Monogr. Phan. 7: 921. 1891.
[Between Maracai and Choroni, 4,000 ft., 12/12/56], *Fendler 1834.*

Miconia tovarensis Cogn., Monogr. Phan. 7: 917. 1891.
[Colonia Tovar, 6,500 ft., 29/4/54], *Fendler 419* (G, photo F, MO).
= *Miconia rubens* Naudin var. *rubens*

Tibouchina moritziana Cogn., Monogr. Phan. 7: 259. 1891. *Fendler 404* p.p. (MO).
= *T. geitneriana* (Schltr.) Cogn.

MELIACEAE

Trichilia montana H.B.K. var. **fendleriana** C. DC., Monogr. Phan. 1: 654. 1878.
[Colonia Tovar, 6,300 ft., 17/5/54, 21/6/55, 24/10/55], *Fendler 139* (G, photo F).
= *Trichilia pallida* Sw.

MONIMIACEAE

Siparuna venezuelensis Perkins, Bot. Jahrb. Syst. 28: 679. 1901.
[Between Valencia and Campanero, 7/4/57], *Fendler 2358.*

MYRSINACEAE

Ardisia robinsonii Mez, Pflanzenr. 4, Fam. 236: 77. 1902.
[Between Caracas and Colonia Tovar, 6,000 ft., 30/4/57], *Fendler 2357* (GH, photo F).

Conomorpha caracasana Mez, Pflanzenr. 4, Fam. 236: 260. 1902.
[Colonia Tovar, 6,500 ft.], *Fendler 751* (MO, photo F).

Conomorpha glabra Mez, Pflanzenr. 4, Fam. 236: 254. 1902.
[High mountains around Colonia Tovar, 7,000 ft., 19/3/55, 23/6/55], *Fendler 752* (paratype, MO, photo F).

Conomorpha laurifolia Mez, Pflanzenr. 4, Fam. 236: 254. 1902.
[Crest of mountains near Colonia Tovar, 7,000 ft., 9/11/54, 14/2/55], *Fendler 756* (G, MO, photo F).

Cybianthus fendleri Mez, Pflanzenr. 4, Fam. 236: 218. 1902.
[Between Petaquire and Colonia Tovar, 6,800 ft., 11/2/57], *Fendler 2015* (G, GH, MO, photo F).

Cybianthus klotzschii Mez, Pflanzenr. 4, Fam. 236: 180. 1902.
[Colonia Tovar, 7,000 ft., 31/8/54, 1/9/54], *Fendler 757* (GH, 3 sheeets, MO).

Parathesis moritziana Mez, Pflanzenr. 4, Fam. 236: 180. 1902.
[Colonia Tovar, 6,500 ft., 6/4/54], *Fendler 754* (holotype, MO).

ORCHIDACEAE

Cranichis fendleri Schltr., Repert. Spec. Nov. Regni Veg. Beih. 6: 30. 1919.
No information in notebook. *Fendler 2135.*

Gomphichis psilosepala Renz, Candollea 11: 245. 1948.
No information in notebook. *Fendler 1402* (isotype, MO).

Liparis fendleri Schltr., Repert. Spec. Nov. Regni Veg. Beih. 6: 32. 1919.
No information in notebook. *Fendler 1422* (MO).
= *Liparis brachystalix* Reichb. f.

Physurus brachyrrhynchus Reichb. f., Xenia Orch. 2: 184. 1873.
Fendler s.n.
= *Aspidogne brachyrrhyncha* (Reichb. f.) Garay

Physurus hyphaematicus Reichb. f., Xenia Orch. 2: 184. 1873.
Fendler s.n.
= *Aspidogne hyphaematica* (Reichb. f.) Garay

Physurus xystophyllus Reichb. f., Xenia Orch. 2: 183. 1873.
Fendler s.n.

Pleurothallis apiculata Lindley, Fol. Orch. Pleuroth. 17. 1859.
No information in notebook. *Fendler 2155* (K).

Pleurothallis clandestina Lindley, Fol. Orch. Pleuroth. 43. 1859.
No information in notebook. *Fendler 2148* (K).

Pleurothallis exasperata Lindley, Fol. Orch. Pleuroth. 15. 1859.
No information in notebook. *Fendler 1490* (K).
= *Myoxanthus exasperatus* (Lindley) Luer

Pleurothallis viridula Lindley, Fol. Orch. Pleuroth. 19. 1859.
No information in notebook. *Fendler 1486* (K).
= *Restrepiopsis viridula* (Lindley) Luer

Stelis alata Lindley, Fol. Orch. Stelis, 18. 1858.
No information in notebook. *Fendler 2154* (K).

Stelis coriifolia Lindley, Fol. Orch. Stelis, 18. 1858.
No information in notebook. *Fendler 2444* (K).

Stelis fendleri Lindley, Fol. Orch. Stelis, 18. 1858.
No information in notebook. *Fendler 1470* (K, MO).

Stelis humulis Lindley, Fol. Orch. Stelis, 10. 1858.
No information in notebook. *Fendler 1467* (K).

Stelis lutea Lindley, Fol. Orch. Stelis, 7. 1858.
No information in notebook. *Fendler 1461* (K).

Stelis muscifera Lindley, Fol. Orch. Stelis, 2. 1858.
No information in notebook. *Fendler 1460* (K).

Stelis muscosa Lindley, Fol. Orch. Stelis, 7. 1858.
No information in notebook. *Fendler 1468* (K).

Stelis tenuilabris Lindley, Fol. Orch. Stelis, 18: 1858.
No information in notebook. *Fendler 1469* (K).
No information in notebook. *Fendler 1471* (K, MO).

PASSIFLORACEAE

Passiflora velata Mast., Fl. Bras. 13(1): 560. 1872.
[Between Turmero and La Victoria, 2,000 ft., 14/3/57], *Fendler 2329* (lectotype, designated by Killip, 1938, K).
= *Passiflora serrulata* Jacq.

PIPERACEAE

Peperomia adscendens C. DC., J. Bot. 4: 140. 1866.
[Colonia Tovar, 6,500 ft., 1/4/54, 20/5/54, 3/6/55], *Fendler 1153* (holotype, G-DC; isotypes, GH, K, MO, NY, PH; also the type of *Peperomia glabra* C. DC.).

Peperomia blanda H.B.K. var. **dissimilis** C. DC., Prodr. 16(1): 459. 1869.
[A few mi. W of Colonia Tovar, 7,000 ft., 28/6/55], *Fendler 1170* (GH, MO, NY).

Peperomia carlosiana C. DC., J. Bot. 4: 140. 1866.
[Valley of San Carlos River, 3,500 ft., 25/10/54], *Fendler 1148* (holotype, G, photo F).
= *Peperomia lanceolata-peltata* var. *carlosiana* (C. DC.) Trelease & Yuncker

Peperomia choroniana C. DC., J. Bot. 4: 141. 1866.
[Between Maracai and Choroni, 3,000 ft., 12/12/57], *Fendler 2402* (holotype, G, photo F).

Peperomia decurrens C. DC., J. Bot. 4: 143. 1866.
[High mountains E of Colonia Tovar, 7,000 ft., 28/9/55], *Fendler 1169* (G, photo F).

Peperomia diffusa C. DC., J. Bot. 4: 133. 1866.
[A few mi. S of Colonia Tovar; Biscaina, 3,000–4,000 ft., 18/5/55, 5/6/55], *Fendler 1178* (holotype, G-DC; isotypes, GH, K, MO, NY, PH).

Peperomia ellipticifolia C. DC., Prodr. 16(1): 463. 1866.
[Colonia Tovar, 6,500 ft., 10/5/54, 14/5/55], *Fendler 1171* (holotype, G-DC; isotype, GH).
= *Peperomia blanda* (Jacq.) H.B.K.

Peperomia ernstiana C. DC., Prodr. 16(1): 397. 1869.
[Near the River Tuy, 5,000–5,500 ft., 2/6/54, 29/7/54, 20/6/55, 3/7/55], *Fendler 1163* (holotype, G-DC; isotypes, GH, MO, NY, PH).
= *Peperomia venezueliana* C. DC.

Peperomia fendleriana C. DC., Prodr. 16(1): 460. 1869.
[Colonia Tovar, 6,500–7,000 ft., 20/5/54, 16/6/54], *Fendler 1174* (syntype, G-DC; isotypes, GH, MO, NY, PH).

Peperomia fragrans C. DC., J. Bot. 4: 140. 1866.
[Maya, banks of River Tuy, 3,000 ft., 20/6/55], *Fendler 1156* (holotype, G-DC; isotypes, GH, K).

Peperomia glabra C. DC., J. Bot. 4: 143. 1866.
[Colonia Tovar, 6,500–7,000 ft., 25/5/54], *Fendler 1153* (holotype, K; isotype, GH; also the type collection of *Peperomia adscendens* C. DC.
= *Peperomia adscendens* C. DC.

Peperomia laevis C. DC., J. Bot. 4: 139. 1866.
[6 mi. SE of Colonia Tovar, 6,000 ft., 7/5/55], *Fendler 1164* (G, photo F; isotype, GH).
= *Peperomia alata* Ruíz Lopez & Pavón

Peperomia lanceolata-peltata C. DC., J. Bot. 4: 136. 1866.
[Biscaina, 3,000 ft., 13/8/55], *Fendler 1149* (syntype (at G-DC) with *Hoffmann 414* (at B); isosyntypes, GH, K, MO, PH).

Peperomia linearis C. DC., J. Bot. 4: 145. 1866.
[Colonia Tovar, 6,500–7,000 ft., 17/6/54, 3/11/56], *Fendler 1176* (syntype with *Jameson s.n.*, both G-DC; isosyntypes, GH, MO, NY, PH).
= *Peperomia swartziana* Miq.

Peperomia magnoliifolia A. Dietr. var. **emarginulata** C. DC., Prodr. 16(1): 427. 1869.
[Near Colonia Tovar, 6,500–7,000 ft., 25/5/54], *Fendler 1152* (also cited as a type of *Peperomia decurrens*) (lectotype, G-DC (per Trel. & Yuncker, Piperac. No. S. Amer. 685. 1950), isolectotypes, GH, MO, NY, PH).
= *Peperomia obtusifolia* (L.) A. Dietr. var. *emarginata* (C. DC.) Trel. & Yuncker

Peperomia patula C. DC., J. Bot. 4: 133. 1866.
[Near Colonia Tovar, 6,500 ft., 16/5/54, 26/11/56], *Fendler 1166* (holotype, G, photo F).

Peperomia pseudodependens C. DC., J. Bot. 4: 137. 1866.
[La Victoria, 2,000 ft., 20/11/56], *Fendler 1817* (holotype, G, photo F; isotype, GH).

Peperomia pseudopeltoidea C. DC., Prodr. 16(1): 434. 1869.
[Colonia Tovar, 6,500 ft., 6/6/54, 16/5/55], *Fendler 1150b* (G, photo F).

Peperomia purpurella C. DC., Prodr. 16(1): 414. 1869.
[River Tuy below Colonia Tovar, 5,000 ft., 29/8/54], *Fendler 1161* (G, photo F).
= *Peperomia patula* C. DC.

Peperomia reflexa (L.) A. Dietr. var. *coriacea* C. DC., Prodr. 16(1): 452. 1869.

[Colonia Tovar, 6,500 ft., 3/4/54, 2/5/54, 5/8/54], *Fendler 1183* (holotype, G-DC, isotypes, GH, MO, NY, PH).
= *Peperomia reflexa* (L.) A. Dietr.

Peperomia san-carlosiana C. DC., J. Bot. 4: 138. 1866.
[San Carlos River valley, 3,500 ft., 7/9/54], *Fendler 1151* (holotype, G, photo F).

Peperomia succulenta C. DC., J. Bot. 4: 142. 1866.
[10 mi. S of Colonia Tovar, 3,500 ft., 10 mi. S of Colonia Tovar, 18/5/55], *Fendler 1157* (holotype, G, photo F; isotype, K).

Peperomia tenella A. Dietr. var. **glabra** C. DC., Prodr. 16(1): 397. 1869.
[Between Maracai and Choroni, 3,000 ft., 12/12/56], *Fendler 1818* (holotype, G-DC; isotypes, GH, K, MO, PH p.p.).

Peperomia tovariana C. DC., Prodr. 16(1): 404. 1869.
[Between Colonia Tovar and Petaquire, 19/4/55], *Fendler 1168* (syntype at G-DC with *Moritz 1941* (at BM); isosyntypes, GH, MO, NY, PH).

Peperomia trinervula C. DC., Prodr. 16(1): 420. 1869.
[High mountains E of Colonia Tovar, 7,000 ft., 28/9/55], *Fendler 1167* (lectotype, G-DC; isolectotype, GH).

Peperomia venezueliana C. DC., J. Bot. (Hooker) 4: 139. 1866.
[Between Colonia Tovar and Petaquire, 6,500 ft., 22/4/58], *Fendler 2618* (holotype, G, photo F).

Piper caracasanum Bredem. ex Link var. **firmius** C. DC., Prodr. 16(1): 306. 1869.
[Colonia Tovar, 6,000 ft., 28/4/54, 7/4/54], *Fendler 1143* (syntype at G-DC with *Bredemeyer 679* (at B-Willd.); 2 sheets at GH; isotype, GH).
= *Piper caracasanum* Bredem. ex Link

Piper cumbotianum C. DC., Prodr. 16(1): 268. 1869.
[Between Agua Blanca and Cumbote, 5,000 ft., 30/1/58], *Fendler 2571* (G, photo F).

Piper fendlerianum C. DC., J. Bot. 4: 213. 1866.
[10 mi. E of Colonia Tovar, 7,500 ft., 26/5/55, 17/6/55], *Fendler 1140* (G, photo F; isotypes, GH, K, MO, NY, PH).

Piper glanduligerum C. DC., J. Bot. 4: 215. 1866.
[Colonia Tovar, 6,500 ft., 6/4/54, 27/6/56], *Fendler 1137* (syntype, G, photo F; isosyntypes, GH, MO, NY, US).

Piper nobile C. DC., Prodr. 16(1): 289. 1869.
[Colonia Tovar, 6,500 ft., 16/6/55], *Fendler 1144* (holotype, G-DC; isotypes, GH, MO, NY, PH).

Piper ovale C. DC., J. Bot. 4: 166. 1866.
[A few mi. SE of Colonia Tovar, 4,000 ft., 27/2/57], *Fendler 2398* (syntype, G-DC; isosyntype, GH).
= *Piper crassinervium* H.B.K.

Piper tovarense Trel. & Yuncker, Piperac. N. South Amer. 1: 27, fig. 17. 1950.
[10 mi. E of Colonia Tovar, 7,000 ft., 17/6/55], *Fendler 1145* (holotype, GH).

Piper tristemon C. DC., Prodr. 16(1): 328. 1869.
[10 mi. E of Colonia Tovar, 7,500 ft., 26/5/55, 17/6/55], *Fendler 1141* (holotype, G-DC, photo F; isotypes, GH, MO).

Piper venezuelense C. DC., J. Bot. 4: 216. 1866.
[Between Agua Blanca and Cumbote, 5,000 ft., 30/1/58], *Fendler 2572* (holotype, G-DC, photo F; isotypes, GH, MO, PH).
= *Piper glabrescens* (Miq.) C. DC. var. *venezuelense* (C. DC.) Trel. & Yuncker

Piper victorianum C. DC., J. Bot. 4: 218. 1866.
[La Victoria, 2,000 ft., 21/11/56], *Fendler 1139* (holotype, G-DC, photo F; isotypes, GH, K, MO, PH).
= *Piper amalgo* var. *medium* (Jacq.) Yuncker

POACEAE

Chusquea fendleri Munro, Trans. Linn. Soc. 26: 61. 1868.
[In and about Colonia Tovar, common, 6,000–7,900 ft., 17/4/55], *Fendler 1627* (holotype, K; isotype, MO).

PODOCARPACEAE

Podocarpus harmsianus Pilger, Pflanzenr. IV. 5(Heft 18): 69. 1903.
[Colonia Tovar, 6,500 ft., 6/4/54], *Fendler 1289.*
= *Prumnopitys harmsiana* (Pilger) Laubenf.

POLYGALACEAE

Polygala fendleri Chodat, Mém. Soc. Phys. Genève 31, pt. 2, no. 2: 167. 1893.
[A few mi. SW of Colonia Tovar, 5,000 ft., 13/9/55, 8/9/56], *Fendler 238* (G).

Polygala tovarensis Chodat, Mém. Soc. Phys. Genève 31, pt. 2, no. 2: 32. 1893.
[Caracas; also a few mi. W of Colonia Tovar, 500–6,500 ft., 31/1/54, 13/9/55, 19/7/56], *Fendler 240* (G).

Securidacea fendleri Chodat, Bull. Herb. Boissier 3: 545. 1895.
Fendler s.n.

RUBIACEAE

Cephaelis aneurophylla Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 63. 1930.
[Between Maracai and Choroni, 5,000 ft., 12/12/56], *Fendler 1979* (holotype, GH; isotype, K).
= *Psychotria aneurophylla* (Standl.) Steyerm.

Cephaelis macrocarpa Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 64. 1930.
[Between Maracai and Choroni, 5,000 ft., 12/12/56], *Fendler 1990* (holotype, GH; isotype, K).
= *Psychotria costanensis* Steyerm. subsp. *costanensis*

Elaeagia karstenii Standley, Field Columbian Mus., Bot. Ser. 8: 50. 1930.
[Colonia Tovar, 13/8/54], *Fendler 594* (holotype, GH; isotypes, F, MO).

Malanea fendleri Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 61. 1930.
[Between Petaquire and Cariaca, 6,000 ft., 12/2/58], *Fendler 2555* (holotype, GH).

Malanea hirsuta Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 65. 1930.
[A few mi. S of Colonia Tovar, 3,500 ft., 16/5/55], *Fendler 569* (holotype, GH; isotypes, K, M, MO, Y).

Manettia schumanniana Sprague, Bull. Herb. Boiss. 2(5): 834. 1905.
[A few mi. E of Colonia Tovar, 7,500 ft., 5/1/57], *Fendler 589.*

Palicourea fendleri Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 65. 1930.
[Between Maracai and Choroni, 5,000 ft., 29/1/57], *Fendler 1983* (holotype, GH, photo F; isotype, K).

Rudgea apodantha Standley, Publ. Field Columbian Mus., Bot. Ser. 8: 72. 1930.
[Between Petaquire and the sea, 4,000 ft., 9/2/57], *Fendler 1993* (holotype, GH, photo F; isotype, K).

SAPINDACEAE

Matayba longipes Radlkofer, Sitzungsber. Math-Phys. Cl. Königl. Bayer. Akad. Wiss. München 9: 626. 1879.
[Colonia Tovar, 6,500 ft., 28/6/56], *Fendler 1748* (holotype, G, photo F; isotype, MO).

SAPOTACEAE

Crepindodendron crotonoides Pierre, Not. Bot. Sap. 28. 1890.
[Seashore near Colombia, 100 ft., 26/1/57], *Fendler 749* (holotype, P).
= *Pouteria crotonoides* (Purre) Baehni

SOLANACEAE

Cestrum laetum Francey, Candollea 6: 378. 1935.
[Colonia Tovar, 6,500 ft., 13/4/54, 7/5/54], *Fendler 955* (holotype, NY).

Cestrum tovarense Francey, Candollea 6: 388. 1935.
[Colonia Tovar, 6,000 ft., 31/8/55], *Fendler 962* (holotype, NY; isotype, MO).

Saracha nitida Bitter, Repert. Spec. Nov. Regni Veg. 19: 265. 1924.
[10 mi. E of Colonia Tovar, 17/6/55, 21/9/55], *Fendler 1007* (G, photo F).

Solanum tovarense Bitter, Repert. Spec. Nov. Regni Veg. 18: 65. 1922.
[Colonia Tovar, 6,000 ft., 27/4/54, 16/8/55, 22/9/55], *Fendler 980* (G, photo F).

STYRACACEAE

Styrax macrotrichus Perkins, Repert. Spec. Nov. Regni Veg. 2: 23. 1906.
[A few mi. SE of Colonia Tovar, 4,500 ft., 9/3/55], *Fendler 746* (G, MO, photo F).

TURNERACEAE

Piriqueta tovarensis Urban, Jahrb. Königl. Bot. Gart. Berlin 2: 69. 1883.
[Savannahs S of Colonia Tovar, 4,000 ft., 13/9/55], *Fendler 115.*

URTICACEAE

Hemistylis macrostachya Wedd., Ann. Sci. Nat. (Paris) 4(1): 208. 1854.
[Between Caracas and La Guayra, 1,000 ft., 16/8/55], *Fendler 1259* (G, photo F).

Hemistylis odontophylla Wedd., Prodr. 16(1): 235. 1869.
[La Victoria, 2,000 ft., 21/11/56], *Fendler 1827* (G, photo F).

Phenax uliginosus Wedd., Ann. Sci. Nat. (Paris) 4(1): 192. 1854.
[Colonia Tovar, 31/4/54, 21/8/55], *Fendler 1268* (G, MO, photo F).

Pilea dauciodora Wedd., Ann. Sci. Nat. (Paris) ser. 3. 18: 223. 1852.
[High mountains around Colonia Tovar, 7,000 ft., 10/5/54, 24/6/55], *Fendler 1246* (G, MO, photo F).

Pilea mollis Wedd., Arch. Mus. Hist. Nat. 8: 251. 1855.
[River Tuy below Colonia Tovar, 4,000–5,500 ft., 2/7/54, 29/8/54, 22/4/58], *Fendler 1241* (G, MO, photo F).

Pilea urticella Wedd., Prodr. 16(1): 157. 1869.
[Between Valencia and Campanero, 4,000 ft., 7/3/57], *Fendler 2429* (G, MO, photo F).

Pouzolzia acalyphioides Wedd., Prodr. 16(1): 234. 1869.
[Biscaina, 3,000 ft., 10/5/55], *Fendler 1264* (G, photo F).

VERBENACEAE

Aegiphila fendleri Moldenke, Repert. Spec. Nov. Regni Veg. 33: 121. 1933.
[Between Agua Blanca and Cumbote, 4,000 ft., 30/1/58], *Fendler 2032* (holotype, GH; isotypes, G, K).

Aegiphila floribunda Moritz & Moldenke, Repert. Spec. Nov. Regni Veg. 33: 122. 1933.
[Colonia Tovar, 6,000 ft., 13/6/55, 16/6/55], *Fendler 845* (MO, W, photo F).

Aegiphila lewisiana Moldenke, Repert. Spec. Nov. Regni Veg. 33: 131. 1933.
[Between Caracas and La Guayra, 2,000 ft., 16/8/55], *Fendler 844.*

Citharexylum venezuelense Moldenke, Repert. Spec. Nov. Regni Veg. 37: 237. 1934.
[Between Caracas and La Guayra, 1,000 ft., 16/8/55], *Fendler 1298.*

Appendix II

List of Fendler Venezuelan collections cited in Appendix I by number and their basionyms.

27 *Cleome moritziana* Klotzsch ex Eichler (Capparaceae)
115 *Piriqueta tovarensis* Urban (Turneraceae)
139 *Trichilia montana* H.B.K. var. *fendleriana* C. DC. (Meliaceae)
177 *Protium laxiflorum* Engl. var. *fendleri* Engl. (Burseraceae)
196 *Rollinia fendleri* R. E. Fries (Annonaceae)
215 *Maytenus fendleri* Briq. (Celastraceae)
238 *Polygala fendleri* Chodat (Polygalaceae)
240 *Polygala tovarensis* Chodat (Polygalaceae)
248 *Canavalia fendleri* Piper (Fabaceae)
344 *Mimosa tovarensis* Benth. (Fabaceae)
404 *Tibouchina moritziana* Cogn. (Melastomataceae)
404 *Henriettella tovarensis* Cogn. var. *angustifolia* Cogn. (Melastomataceae)
414 *Miconia resimoides* Cogn. (Melastomataceae)
415 *Miconia multinervulosa* Cogn. (Melastomataceae)
419 *Miconia tovarensis* Cogn. (Melastomataceae)
432 *Heterotrichum glandulosum* Cogn. (Melastomataceae)
436 *Clidemia ciliata* D. Don var. *grandifolia* Cogn. (Melastomataceae)
438 *Clidemia fendleri* Cogn. (Melastomataceae)
439 *Leandra fendleri* Cogn. (Melastomataceae)
444 *Henriettella tovarensis* Cogn. (Melastomataceae)
444 *Henriettella tovarensis* Cogn. var. *angustifolia* Cogn. (Melastomataceae)
489 *Edmondia spectabilis* Cogn. (Cucurbitaceae)

490 *Gurania wagneriana* Cogn. (Cucurbitaceae)
502 *Sicyos macrocarpus* Cogn. (Cucurbitaceae)
503 *Echinocystis polycarpa* Cogn. (Cucurbitaceae)
513 *Begonia fagopyroides* Kunth & Bouché var. *fendleriana* A. DC. (Begoniaceae)
524 *Hydrocotyle venezuelensis* Rose ex Mathias (Apiaceae)
529 *Dendropanax fendleri* Seemann (Araliaceae)
569 *Malanea hirsuta* Standley (Rubiaceae)
589 *Manettia schumanniana* Sprague (Rubiaceae)
594 *Elaeagia karstenii* Standley (Rubiaceae)
625 *Mikania racemulosa* Klatt (Asteraceae)
626 *Mikania hexagona* B. L. Robinson (Asteraceae)
634 *Eupatorium neriifolium* B. L. Robinson (Asteraceae)
638 *Eupatorium xestolepis* B. L. Robinson var. *xestolepis* (Asteraceae)
647 *Eupatorium steetzii* B. L. Robinson (Asteraceae)
651 *Trichogonia rhadinocarpa* B. L. Robinson (Asteraceae)
702 *Senecio cucullatus* Klatt (Asteraceae)
718 *Hieracium tovarense* Fries (Asteraceae)
746 *Styrax macrotrichus* Perkins (Styracaceae)
749 *Crepindodendron crotonoides* Pierre (Sapotaceae)
751 *Conomorpha caracasana* Mez (Myrsinaceae)
754 *Parathesis moritziana* Mez (Myrsinaceae)
756 *Conomorpha laurifolia* Mez (Myrsinaceae)
757 *Cybianthus klotzschii* Mez (Myrsinaceae)
794 *Monopyle leucantha* Moritz ex Benth. (Gesneriaceae)
830 *Symbolanthus magnificus* Gilg (Gentianaceae)
844 *Aegiphila lewisiana* Moldenke (Verbenaceae)
845 *Aegiphila floribunda* Moritz & Moldenke (Verbenaceae)
876 *Salvia tovariensis* Briq. (Lamiaceae)
879 *Stachys fendleri* Briq. (Lamiaceae)
941 *Ipomoea fruticosa* Kuntze (Convolvulaceae)
955 *Cestrum laetum* Francey (Solanaceae)
962 *Cestrum tovarense* Francey (Solanaceae)
980 *Solanum tovarense* Bitter (Solanaceae)
1007 *Saracha nitida* Bitter (Solanaceae)
1030 *Dipladenia fendleri* Muell. Arg. (Apocynaceae)
1032 *Amblyanthera fendleri* Muell. Arg. (Apocynaceae)
1095 *Gymnobalanus latifolia* Meissn. (Lauraceae)
1098 *Mespilodaphne vaginans* Meissn. (Lauraceae)
1101 *Dendrophthora eichleriana* Urban (Loranthaceae)
1102 *Phoradendron fendlerianum* Eichler (Loranthaceae)
1104 *Dendrophthora basiandra* Kuijt (Loranthaceae)
1105 *Phoradendron rigidum* Urban (Loranthaceae)
1106 *Phoradendron tubulosum* Urban (Loranthaceae)
1108 *Phoradendron ovalifolium* Urban (Loranthaceae)
1115 *Phoradendron cuneifolium* Urban (Loranthaceae)
1125 *Stachyphyllum fendleri* van Tiegh. (Loranthaceae)
1127 *Hedyosmum pseudoandromeda* Solms-Laub. (Chloranthaceae)
1137 *Piper glanduligerum* C. DC. (Piperaceae)
1139 *Piper victorianum* C. DC. (Piperaceae)
1140 *Piper fendlerianum* C. DC. (Piperaceae)
1141 *Piper tristemon* C. DC. (Piperaceae)
1143 *Piper caracasanum* Bredem. ex Link var. *firmius* C. DC. (Piperaceae)
1144 *Piper nobile* C. DC. (Piperaceae)
1145 *Piper tovarense* Trel. (Piperaceae)
1148 *Peperomia carlosiana* C. DC. (Piperaceae)
1149 *Peperomia lanceolata-peltata* C. DC. (Piperaceae)
1150b *Peperomia pseudopeltoidea* C. DC. (Piperaceae)
1151 *Peperomia san-carlosiana* C. DC. (Piperaceae)
1152 *Peperomia magnoliifolia* A. Dietr. var. *emarginulata* C. DC. (Piperaceae)
1153 *Peperomia adscendens* C. DC. (Piperaceae)
1153 *Peperomia glabra* C. DC. (Piperaceae)
1156 *Peperomia fragrans* C. DC. (Piperaceae)
1157 *Peperomia succulenta* C. DC. (Piperaceae)
1161 *Peperomia purpurella* C. DC. (Piperaceae)
1163 *Peperomia ernstiana* C. DC. (Piperaceae)
1164 *Peperomia laevis* C. DC. (Piperaceae)
1166 *Peperomia patula* C. DC. (Piperaceae)
1167 *Peperomia trinervula* C. DC. (Piperaceae)
1168 *Peperomia tovariana* C. DC. (Piperaceae)
1169 *Peperomia decurrens* C. DC. (Piperaceae)
1170 *Peperomia blanda* H.B.K. var. *dissimilis* C. DC. (Piperaceae)
1171 *Peperomia ellipticifolia* C. DC. (Piperaceae)
1174 *Peperomia fendleriana* C. DC. (Piperaceae)
1176 *Peperomia linearis* C. DC. (Piperaceae)
1178 *Peperomia diffusa* C. DC. (Piperaceae)
1183 *Peperomia reflexa* A. Dietr. var. *coriacea* C. DC. (Piperaceae)
1191 *Euphorbia tovarensis* Boiss. (Euphorbiaceae)
1202 *Pedilanthus fendleri* Boiss. (Euphorbiaceae)
1208 *Tragia fendleri* Muell. Arg. (Euphorbiaceae)
1230 *Excoecaria obtusiloba* Muell. Arg. (Euphorbiaceae)
1241 *Pilea mollis* Wedd. (Urticaceae)
1246 *Pilea dauciodora* Wedd. (Urticaceae)
1259 *Hemistylis macrostachya* Wedd. (Urticaceae)
1264 *Pouzolzia acalyphioides* Wedd. (Urticaceae)
1272 *Alchornea grandiflora* Muell. Arg. (Euphorbiaceae)
1289 *Podocarpus harmsianum* Pilger (Podocarpaceae)
1298 *Citharexylum venezuelense* Moldenke (Verbenaceae)
1327 *Philodendron fraternum* Schott (Araceae)
1329 *Philodendron deviatum* Schott (Araceae)
1336 *Anthurium nymphaeifolium* K. Koch & C. Bouché var. *ovatum* Engl. (Araceae)
1343 *Anthurium fendleri* Schott (Araceae)
1346 *Anthurium bredemeyeri* Schott var. *elongata* Engl. (Araceae)
1348 *Asplundia fendleri* Harling (Cyclanthaceae)
1422 *Liparis fendleri* Schltr. (Orchidaceae)
1460 *Stelis muscifera* Lindley (Orchidaceae)
1461 *Stelis lutea* Lindley (Orchidaceae)
1467 *Stelis humulis* Lindley (Orchidaceae)
1468 *Stelis muscosa* Lindley (Orchidaceae)
1469 *Stelis tenuilabris* Lindley (Orchidaceae)
1470 *Stelis fendleri* Lindley (Orchidaceae)
1471 *Stelis tenuilabris* Lindley (Orchidaceae)
1486 *Pleurothallis viridula* Lindley (Orchidaceae)
1490 *Pleurothallis exasperata* Lindley (Orchidaceae)
1508 *Tillandsia compacta* Griseb. (Bromeliaceae)
1509 *Tillandsia grisebachiana* Baker (Bromeliaceae)
1514 *Tillandsia pleiosticha* Griseb. (Bromeliaceae)
1515 *Tillandsia fendleri* Griseb. (Bromeliaceae)
1516 *Tillandsia excelsa* Griseb. var. *latifolia* Griseb. (Bromeliaceae)
1517 *Tillandsia ventricosa* Griseb. (Bromeliaceae)

1521 *Nidularium albo-roseum* Griseb. (Bromeliaceae)
1523 *Tillandsia caribaea* Lyman B. Smith (Bromeliaceae)
1524 *Tillandsia incurva* Griseb. (Bromeliaceae)
1525 *Tillandsia robusta* Griseb. (Bromeliaceae)
1530 *Tillandsia myriantha* Baker (Bromeliaceae)
1546 *Smilax scabriuscula* Humb. & Bonpl. ex Willd. var. *fendleri* A. DC. (Liliaceae)
1550 *Pitcairnia fendleri* Mez (Bromeliaceae)
1552 *Tillandsia longifolia* Baker (Bromeliaceae)
1555 *Phaeosphaerion efoveolatum* C. B. Clarke (Commelinaceae)
1591 *Rhynchospora rudis* C. B. Clarke (Cyperaceae)
1627 *Chusquea fendleri* Munro (Poaceae)
1748 *Matayba longipes* Radlkofer (Sapindaceae)
1750 *Machaerium moritzianum* Benth. (Fabaceae)
1761 *Phoradendron tovarense* Urban (Loranthaceae)
1762 *Phoradendron longipetiolatum* Urban (Loranthaceae)
1771 *Tillandsia acorifolia* Griseb. (Bromeliaceae)
1810 *Phoradendron venezuelense* Trel. (Loranthaceae)
1811 *Phoradendron bilineatum* Urban (Loranthaceae)
1817 *Peperomia pseudodependens* C. DC. (Piperaceae)
1818 *Peperomia tenella* A. Dietr. var. *glabra* C. DC. (Piperaceae)
1825 *Acalypha villosa* Jacq. var. *intermedia* Muell. Arg. (Euphorbiaceae)
1827 *Hemistylis odontophylla* Wedd. (Urticaceae)
1830 *Meriania subumbellata* Cogn. (Melastomataceae)
1832 *Arthrostemma alatum* Triana (Melastomataceae)
1834 *Miconia rubens* Naudin var. *latifolia* Cogn. (Melastomataceae)
1835 *Miconia fendleriana* Cogn. (Melastomataceae)
1836 *Miconia fendleriana* Cogn. (Melastomataceae)
1845 *Heterotrichum lucidum* Triana (Melastomataceae)
1865 *Machaerium tovarense* Pittier (Fabaceae)
1866 *Machaerium mortizianum* Benth. (Fabaceae)
1947 *Eupatorium tovarense* B. L. Robinson (Asteraceae)
1957 *Piptocarpha sprucei* Baker (Asteraceae)
1967 *Clibadium parviceps* S. F. Blake (Asteraceae)
1979 *Cephaelis aneurophylla* Standley (Rubiaceae)
1983 *Palicourea fendleri* Standley (Rubiaceae)
1990 *Cephaelis macrocarpa* Standley (Rubiaceae)
1993 *Rudgea apodantha* Standley (Rubiaceae)
2015 *Cybianthus fendleri* Mez (Myrsinaceae)
2031 *Columnea fendleri* Sprague (Gesneriaceae)
2032 *Aegiphila fendleri* Moldenke (Verbenaceae)
2082 *Ipomoea fruticosa* Kuntze (Convolvulaceae)
2083 *Ipomoea fendleriana* Kuntze (Convolvulaceae)
2084 *Ipomoea alatipes* Hook. (Convolvulaceae)
2119 *Philibertia fendleri* A. Gray (Asclepiadaceae)
2135 *Cranichis fendleri* Schltr. (Orchidaceae)
2148 *Pleurothallis clandestina* Lindley (Orchidaceae)
2154 *Stelis alata* Lindley (Orchidaceae)
2155 *Pleurothallis apiculata* Lindley (Orchidaceae)
2159 *Tillandsia mucronata* Griseb. (Bromeliaceae)
2166 *Tillandsia laxa* Griseb. (Bromeliaceae)

2618 *Peperomia venezueliana* C. DC. (Piperaceae)

AUGUSTUS FENDLER'S VENEZUELAN COLLECTIONS OF FERNS AND FERN ALLIES[1]

Alan R. Smith[2] *and Carol A. Todzia*[3]

ABSTRACT

Augustus Fendler collected over 500 collection numbers of pteridophytes in Venezuela between 1854 and 1858. These collections are noteworthy because of the large number of dispersed duplicates, rarities, and types (44 collection numbers thus far identified) among them. This paper presents an annotated list of Fendler's Venezuelan pteridophyte collections and a historical account of the collections, including a portrayal of Fendler's fascination with ferns.

Augustus Fendler collected in northern Venezuela between 1854 and 1858, where he amassed important collections of angiosperms, ferns, fern allies, lichens, mosses, liverworts, and fungi. Although a general account of his Venezuelan collecting is given in the previous paper (Todzia, 1989), this article deals specifically with his fern collections. Fendler's pteridophyte collections are noteworthy because they represent the first intensive gathering of ferns and fern allies from the Coastal Cordillera of Venezuela, and because they are widely distributed. Consequently, they have become type specimens of a great many fern species. The following account has been assembled with the aid of Fendler's correspondence with Daniel C. Eaton and Asa Gray, at the YU and GH archives, respectively.

Fendler's Venezuelan fern collections as well as his sets of flowering plants were distributed by Asa Gray. As with the angiosperms, Fendler initially retained the first set for himself. In 1859 he received a request from Thomas Moore of the Chelsea Botanic Garden for a set, but since Moore had access to William Hooker's herbarium containing set 2, Fendler decided to sell his first set to Daniel C. Eaton, who was then a student of Gray. He did this because Eaton agreed to publish a list of these collections, and because the collections would then remain in the United States, where Fendler would have easy access to them. In a letter to Eaton, Fendler stated, "The only set remaining with me is set No. 1 which I used for comparison and in which I felt a pride and a pleasure to lay up not only the most complete but also the finest specimens selected from the rest. There was a time when I thought I could never part with these plants. In bringing them up from their hidden places I have neither shun danger nor travelling expenses, and it was chiefly the search after *Ferns*, which induced me to cross the principal chain of the cordillera of the coast upon four different tracks. I therefore need not say how dear they are to me, and I never would have sold them to anyone except to a Botanist, who is able to make the proper use of them" [Fendler to Eaton, 24 January 1859, St. Louis]. Fendler went on to say, "For my part I have neither the necessary books, time, nor herbarium to do it. Great resources undoubtedly are necessary to determine, which of the species are new and which are not; for I have reason to believe that in works on Ferns, with many species, a critical and patient overhauling is very desirable, in order to disperse the existing confusion. I remember to have seen in one herbarium the same species under four different names, one of these specimens was even disposed of under a new genus" [Fendler to Eaton, 24 January 1859, St. Louis]. In total, Fendler sent Eaton close to 500 collection numbers

[1] We thank the archivists and librarians at the Missouri Botanical Garden, Gray Herbarium, and Yale University for aiding in finding some of the sources used in this paper. We benefited from discussions with J. Ewan, R. C. Moran, J. A. Steyermark, and H. van der Werff concerning Fendler in Venezuela. R. C. Moran, C. Blaney, N. Morin, P. E. Berry, G. K. Rogers, and J. Ewan provided helpful comments on various drafts of this manuscript. The junior author was supported by a National Museum Act Fellowship at the Missouri Botanical Garden during the course of the project.

with about 564 sheets. Eaton paid 10 cents a sheet for a total cost of $56.40.

In 1860, Eaton was awarded a Bachelor of Science degree from Harvard University for his dissertation enumerating Fendler's Venezuelan fern collections along with those collected by Wright in Cuba, and a few collections of Schott and Hayes from Panama and Colombia. A year later, Eaton's dissertation was published (Eaton, 1861). Fendler, however, was not pleased with this work. In the following long passage, we can see what a keen observer Fendler was. "In regard to Mr. Eaton's Filices I am sorry to say that I was very much disappointed. Being in possession of the names of Dr. Engelmann's set of ferns as determined by Prof. Mettenius,[4] I was able to compare them with those given by Eaton and find that the names of 146 sp. agree with those determined by Mettenius, while the names of 101 spec. disagree. I am not able to say who is in the right, but should be inclined to depend more upon the one that has the longest experience in the matter [Mettenius]. Such differences of different authors are most discouraging to the student of botany and a severe drawback in the acquisition of knowledge. But what concerns me more immediately and of which I think I have reason to be solicitous, is the readiness with which Mr. Eaton throws different, quite *distinct*, species under one and the same name. I regret this, the more it may be inferred as if I purposely manufactured species for the sake of selling one and the same species over again under different numbers. Having pointed out in Mr. Eaton's set some of the more obscure characters of many species very much resembling each other, I thought I had done something to prevent mistakes. It always seemed to me, that authors who only see 1 or 2 dried specimens of each species ought to pay at least some slight regard to the opinion of a collector who had the best opportunities, and for 4 years availed himself of those opportunities to study the habits of the different ferns, and to observe them in their growing state in the different phases of their growth, not on single specimens or in single localities only, but in hundreds of different places and individuals." Fendler continued: "There may be a dozen species about which I was rather doubtful, but all the rest I consider genuine species; and as soon as I shall have time to examine Dr. Engelmann's set, I shall endeavor to point out the differences in species considered the same by Mr. Eaton. That even the most experient [sic] authors on ferns may sometimes take 2 different species to be one and the same is proved by Prof. Mettenius calling No. 161 'a young specimen of 162.' Now the former (No. 161) is not only different in form but has also 2 to 3 oval tubers, all the fronds die at a certain season of the year, and new fronds make their appearance rather suddenly but not before the commencement of the rainy season; the latter (No. 162) is a perennial plant to be seen at all times of the year and never possessing tubers" [Fendler to Gray, 24 March 1868, St. Louis]. In fact, these two numbers do represent two species (Appendix I), and Fendler was correct.

Nevertheless, Fendler's friendship with Eaton grew, as evidenced by Fendler's 15 letters to Eaton written from Trinidad between 1878 and Fendler's death in 1883. In Trinidad, as in Venezuela, he seems to have been preoccupied with collecting ferns and seems to have particularly relished discussing his Trinidad fern collections with Eaton. Fendler, however, much preferred Venezuela over Trinidad and in his letters to Eaton, Engelmann, and Gray from Trinidad, he often mentioned how much he would like to return to Colonia Tovar. In his last letter to Eaton before his death, Fendler stated, "I long for the cool alpine air (damp though it be) for the deep shades and the eternal silence of those primeval forests, where a quarter of century ago my footsteps were wandering in search of the treasures of botany—especially those of ferns—again to go and see them, and to draw them forth from out their hiding places in the deep dells, or to bring them down from the mountain's high summit" [Fendler to Eaton, 15 June 1882, Port-of-Spain, Trinidad]. At 69, forever the fervent collector, Fendler asked Eaton if the professor could find subscribers to about 40 sets of Venezuelan ferns [Fendler to Eaton, 15 June 1882, Port-of-Spain, Trinidad]. Fendler often wrote to his correspondents that he longed to return to the "land of perpetual peace . . . the happy region of the ferns."

Fendler's Fern Notebook and Collections

Fendler's field notebook in the GH archives is not chronological and consecutive, but rather a catalog of species in taxonomic order. Thus, the number sequence begins with 1 (Marattiaceae), proceeds through the more primitive fern families (Osmundaceae, Schizaeaceae, Hymenophyllaceae, Gleicheniaceae, Cyatheaceae), and then continues with the more advanced ferns, genus by genus, up to number 324. Numbers after 324 were collected

[4] Georg H. Mettenius (1823–1866), German pteridologist, whose fern herbarium is now mostly at B.

after a trip to the United States and after he had distributed some of his material. It is obvious that the notebook was compiled after many of the collections had already been made and put into sequence. Fendler combined collections made on different dates and at different places under a single number. For example, *Fendler 6*, *Anemia villosa*, was collected on nine different dates (according to data on the sheet at YU) and most likely at several different localities during the years 1854, 1855, and 1856.

Fendler probably revisited many collection sites in an attempt to amass additional material of a given number, because he intended to collect in large sets for sale to as many individuals or herbaria as possible. It appears that he tried to collect in sets of 20, although he gathered 40 sheets of *Fendler 23*, *Trichomanes reptans*. The number of collections appears in the upper right-hand corner of the labels on sheets at YU but does not appear on the labels of Fendler collections in other herbaria. In some cases, Fendler kept an account of material of varying stages, e.g., he collected 26 young and 12 old specimens of *Marattia laevis* (*Fendler 3*). In other instances, he recorded the number of specimens in different categories, e.g., he collected 20 specimens of no. 94, *Paesia glandulosa*, and 5 more with the rhizome. For many numbers through about 324, specimens were collected in rather large sets. Thereafter, the sets were generally much smaller, often only a few sheets. Most of the numbers after 324 were gathered in the years 1855 to 1858, whereas most collections of the numbers before 325 were made in 1854, with additions to the set made in 1855 and 1856.

Fendler's keen eye is evident by the fact that, even though he often collected the same species (or number) at different times and/or localities, there are very few mixed gatherings. He must have had a very discriminating eye for differences. When in doubt, he often gave aberrant collections Greek letter designations α and β under the same number, or labeled the additions "ad 56"; sometimes these represent noteworthy taxonomic variations (occasionally different species), sometimes only forms of little taxonomic significance. The following are taxonomically mixed collections: 16, 31, 64, 72, 73, 83, 98, 117, 143, 179, 181, 185, 187, 221, 224, 232, 258?, 259, 293, 294, 322, 324, 364, 378, 380, and 473. Some of these probably represent inadvertent mixing or misnumbering, whereas others are in large genera of great taxonomic difficulty, e.g., *Elaphoglossum*, *Thelypteris*, and *Selaginella*.

Fendler's collection numbers range from 1 to 499. Of these, 44 are thus far identified as types. We have seen specimens or notebook information for all numbers except 2 and 339. In addition, neither we nor Eaton (1861) saw specimens numbered 337, 345, 346, 384, 392, 401, 427, 442, 458, 462, 478, 484, or 490. The notebook at Harvard contains entries for numbers 58 to 499; inexplicably, the early numbers are missing.

Because Fendler gave the same collection number to plants collected at different times and localities, it often is impossible to determine the locality and date of a particular specimen. In a few cases there is only a single date on the specimen and in the notebook. In the list that follows (Appendix I), dates are given only where there is reasonable certainty that the entire gathering was made on a single date at a single place. For those numbers that were collected on more than one date, we give the total number of dates (as indicated from the notebook and on the specimens at YU). For all numbers, the size of the set, when known, is given.

Fendler's Venezuelan pteridophytes were widely distributed, and specimens have been located in the following 16 herbaria: B, BM, BR, CU, F, G, GH, GOET, K, MO, NY, P, PH, S, US, and YU.

APPENDIX I

Determinations of Fendler's pteridophyte collections from Venezuela, Estado Aragua and adjacent states, Colonia Tovar, and vicinity, 1854–1855. The fractional number in square brackets is the number of collection dates listed by Fendler in his notebook and on the set at YU (numerator) over the number of sets (denominator), as indicated on specimens at YU. If a given number was collected on a single date only, the exact date is given. Determinations are by Alan Smith unless otherwise indicated. Abbreviations: JM = John T. Mickel; RT = Rolla M. Tryon; AT = Alice F. Tryon; ME = A. Murray Evans; DL = David B. Lellinger; RM = Robbin C. Moran; BO = Benjamin Øllgaard. (s) = data from specimen at YU; (n) = data from Fendler notebook at GH.

78. *Adiantum henslovianum* Hook.; MO. [2/?]; 3,000–4,000 ft.; around Caracas (n).

79. *Adiantum patens* Willd.; MO, YU. [4/16]; 3,000–4,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).

80. *Adiantum polyphyllum* Willd.; MO, YU—2. [5/20]; 3,000–4,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).

81. *Adiantum deflectens* Martius; LECTOTYPE, US (chosen by Lellinger, Proc. Biol. Soc. Washington 89: 703. 1977) of *A. deflectens* var. *tremulum* Hieron., Bot. Jahrb. Syst. 34: 487 1904, as "*tremula*"; ISOLECTOTYPES, MO—2, YU. [2/20]; 2,000–3,000 ft.; between La Victoria and Biscaina, S of Colonia Tovar (n).

82. *Adiantum lunulatum* Burm. f.; MO, YU. [2/12]; 2,500 ft.; near La Victoria and south of Laguna de Valencia (n).

83. *Adiantum pulverulentum* L.; YU. [3/16]; 2,500–4,000 ft.; a few mi. S and SW of Colonia [Tovar], also Piedernales (n).

83. *Adiantum fructuosum* Sprengel; MO.

84. *Adiantum serratodentatum* Willd.; MO, YU. [2/18]; 2,500–3,500 ft.; Biscaina and Piedernales in savannahs at margin of woods (n).

85. *Adiantum villosum* L.; MO, YU—2. [4/8]; 2,000–3,000 ft.; Piedernales, La Victoria, between Caracas and La Guayra (n).

ad 85. *Adiantum tetraphyllum* Humb. & Bonpl. ex Willd.; YU.

86. *Adiantum pulverulentum* L.; MO, YU. [8/20]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar, also Piedernales (n).

87. *Adiantum petiolatum* Desv.; YU. 25/1/55 [1/2]; 2,000 ft.; Piedernales, near Güigüe (n).

88. *Adiantum macrophyllum* Sw.; MO. [7/21]; 2,500–3,500 ft.; valley of the Tuy River, Maya Piedernales (n).

89. *Pellaea ovata* (Desv.) Weath.; MO—2, YU; det. AT. [7/20]; 6,500 ft.; a few mi. S of Colonia Tovar in a savannah between rocks (n).

90. *Cheilanthes marginata* H.B.K.; MO, YU. [3/20]; 7,000 ft.; a few mi. W of Colonia Tovar (n).

91. *Doryopteris pedata* (L.) Fée var. *palmata* (Willd.) Hicken; MO; YU—2; det. RT. [6/20]; 3,000–4,000 ft.; lower valleys S and SW of Colonia Tovar (n).

92. *Cheilanthes concolor* (Langsd. & Fischer) R. & A. Tryon; MO, YU. [2/20]; 2,000–3,000 ft.; seaside of mountain range between Caracas and Guayra and between Maracai and Choroni (n).

93. *Histiopteris incisa* (Thunb.) J. Smith; MO, YU—3. [2/25]; 7,500 ft.; highest mountains east of Colonia Tovar (n).

94. *Paesia glandulosa* (Sw.) Kuhn; MO, YU—2. [2/25]; 7,500 ft.; highest mountains E of Colonia Tovar (n).

95. *Pteris gigantea* Willd.; MO, US, YU—2. [3/18]; 3,500 ft.; lower valleys S of Colonia [Tovar] (n).

96. *Pteris grandifolia* L.; MO, YU—2. [2/14]; 2,000–2,500 ft.; between Caracas and La Guayra, also above Hacienda Curisal (n).

97. *Pteris consanguinea* Mett. ex Kuhn, Linnaea 36: 89. 1869. ISOSYNTYPES, K—photo US, MO, YU—3. [2/16]; 6,700 ft.; mountains south of Colonia [Tovar] (n).

98. *Pteris podophylla* Sw.; MO, US, YU—2. [4/26]; 5,500–7,000 ft.; valley of the Tuy and headwaters of San Carlos River (n).

98. *Pteris propinqua* Agardh; YU. [?/3]; 7,000 ft. (s).

99. *Pteris propinqua* Agardh; YU. 25/1/55 [1/3]; 2,300 ft.; Piedernales near Güigüe (n).

100. *Lonchitis hirsuta* L.; MO, YU. 5/6/55 [1/20]; 3,200 ft.; small distance above Biscaina, 9 mi. S of Colonia [Tovar] (n).

101. *Pteris deflexa* Link; MO, YU. [5/10]; 6,000 ft.; Colonia Tovar (n).

102. *Pteris deflexa* Link; MO, US, YU—3. [7/20]; 7,000 ft.; a few mi. W of Colonia Tovar, high mountains (n).

103. *Pteris quadriaurita* Retz.; MO, YU. [3/1]; 4,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).

103β. *Pteris quadriaurita* Retz.; YU—2. 26/1/57 [1/1] (s).

104. *Pteridium arachnoideum* (Kaulf.) Maxon; MO, YU—3. [4/20]; 5,000–7,000 ft.; Colonia Tovar (n).

105. *Pteris longifolia* L.; MO, US, YU. [7/20]; 6,000–6,500 ft.; savannah a few mi. S of Colonia [Tovar] (n).

106. *Blechnum occidentale* L.; MO—2. [3/?]; 4,000–6,500 ft.; mountains S of Colonia, also Caracas (n).

107. *Blechnum occidentale* L.; YU; cited by Eaton (1861). [3/?]; 6,800 ft.; a few mi. W of Colonia Tovar (n).

108. *Blechnum occidentale* L.; YU; cited by Eaton (1861). 27/5/54 [1/?]; 6,000 ft.; a few mi. SW of Colonia [Tovar] (n).

109. *Blechnum* hybrid?, possibly *B. occidentale* L. × *B. polypodioides* Raddi; MO—2. [3/?]; 2,000–3,500 ft.; near Caracas, also low valleys S of Colonia [Tovar], Piedernales (n).

110. *Blechnum polypodioides* Raddi; MO—2. [4/?]; 2,000–4,000 ft.; near Caracas, La Victoria (n).

110β. *Blechnum* sp.; YU; cited by Eaton (1861) as *B. polypodioides.*

111. *Blechnum* sp.; YU; cited by Eaton (1861) as *B. longifolium* H.B.K. 25/1/55 [1/?]; 2,300 ft.; Piedernales (n).

112. *Blechnum* ×*caudatum* Cav. [*B. fraxineum* Willd. × *B. occidentale* L.]; MO. [3/?]; 3,000–4,000 ft.; lower valleys a few mi. S and SW of Colonia Tovar (n).

113. *Blechnum* ×*caudatum* Cav. [*B. fraxineum* Willd. × *B. occidentale* L.]; MO. [3/?]; 5,500 ft.; Tuy River valley below Colonia [Tovar] (n).

114. *Blechnum fraxineum* Willd.; MO. [3/?]; 3,000–3,500 ft.; Macarao valley, 9 mi. above Las Aguntas (n).

115. *Blechnum* sp.; YU; cited by Eaton (1861) as *B.*

longifolia H.B.K. [2/?]; 3,000 ft.; Piedernales, also between Caracas and La Guayra (n).

116. *Blechnum* sp.; YU; cited by Eaton (1861) as *B. fendleri* Hook. 25/1/55 [1/?]; 2,300 ft.; Piedernales (n).
117. *Salpichlaena volubilis* (Kaulf.) J. Smith; MO—2. [3/?]; 6,000–7,000 ft.; Colonia Tovar (n).
117. *Arachniodes denticulata* (Sw.) Ching; MO.
118. *Blechnum cordatum* (Desv.) Hieron.; MO. [3/?]; 6,500–7,200 ft.; a few mi. W of Colonia [Tovar] (n).
119. *Blechnum cordatum* (Desv.) Hieron.; MO. [5/?]; 7,000 ft.; a few mi. S and SW of Colonia Tovar (n).
120. *Blechnum* sp.; YU; cited by Eaton (1861) as *Lomaria procera* Sprengel [possibly *B. cordatum* (Desv.) Hieron.]. 16/8/55 [1/?]; 3,000 ft.; between Caracas and La Guayra (n).
121. *Blechnum* aff. *cordatum* (Desv.) Hieron.; MO. 24/6/55 [1/?]; 8,000 ft.; highest mountains 12 mi. E of Colonia Tovar (n).
122. *Blechnum* sp.; YU; cited by Eaton (1861) as *Lomaria procera* Sprengel [possibly *B. cordatum* (Desv.) Hieron.]. No data in notebook.
123. *Asplenium rutaceum* (Willd.) Mett.; MO, US, YU. [3/21]; 6,500 ft.; Colonia Tovar and seaside of mountains (n).
124. *Asplenium cristatum* Lam.; MO, YU. [15/23]; 6,000–7,000 ft.; Colonia Tovar (n).

ad 124. *Asplenium cristatum* Lam.; YU. 25/1/55 [1/8] (s).

124β. *Asplenium* aff. *cristatum* Lam.; MO, US, YU. [5/11]; rachis winged.
125. *Asplenium flabellulatum* Kunze; MO, US, YU—3. [6/23]; 6,000–7,000 ft.; Colonia Tovar (n).
125. *Asplenium flabellulatum* Kunze var. *partitum* Klotzsch; MO.
126. *Asplenium radicans* L.; MO—2, US, YU. [5/13]; 6,000–7,000 ft.; around Colonia Tovar (n).
126β. *Asplenium radicans* L.; YU. [?/4].
127. *Asplenium radicans* L.?; MO—2, US, YU. [6/21]; 4,000–5,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).
127β. *Asplenium flabellulatum* Kunze var. *partitum* Klotzsch; YU. 8/1/57 [1/1] (s).
128. *Diplazium cristatum* (Desr.) Alston; MO, US, YU. [6/18]; 6,500 ft.; Colonia Tovar (n).
128β. *Diplazium cristatum* (Desr.) Alston; YU. 9/2/57 [1/1] (s).
129. *Diplazium caracasanum* (Willd.) Kunze ex T. Moore; MO, US, YU. [7/16]; 6,500 ft.; Colonia Tovar (n).
129β. *Diplazium caracasanum* (Willd.) Kunze ex T. Moore; MO, YU. 8/1/57 [1/9] (s).
130. *Asplenium pumilum* Sw.; MO, US, YU. [6/24]; 2,000–4,000 ft.; a few mi. SW of Colonia [Tovar], also near La Victoria and between Caracas and La Guayra (n).
131. *Asplenium obtusifolium* L.; MO, US, YU. [3/22]; 5,000–5,500 ft.; around Colonia Tovar, in wet places on rocks (n).
132. *Asplenium squamosum* L.; MO, YU—2; cited by Morton & Lellinger (1966) at GH, NY. 8/10/55 [1/11]; 7,200 ft.; 5 mi. W of Colonia Tovar, upon rocks (n).
133. *Asplenium formosum* Willd.; MO, US, YU. [5/27]; 4,000 ft.; a few mi. SW of Colonia Tovar, also several mi. above Choroni (n).
134. *Asplenium monanthes* L.; MO, US, YU. [2/23]; 4,000 ft.; a few mi. SW of Colonia [Tovar] (n). One other sheet at MO is *Asplenium cristatum* Lam.
135. *Asplenium harpeodes* Kunze; MO—3, YU. [13/22]; 6,500–7,500 ft.; around Colonia Tovar (n).
136. *Asplenium laetum* Sw., vel aff.; MO, US, YU. [5/20]; 3,000–4,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).
137. *Asplenium raddianum* Gaud.; MO, US, YU—2. [14/20]; 6,000–7,000 ft.; Colonia Tovar (n).
138. *Asplenium claussenii* Hieron., Hedwigia 60: 241. 1918. LECTOTYPE (chosen by Morton & Lellinger, 1966), B; ISOLECTOTYPES, MO, US, YU. [5/20]; 4,000–5,000 ft.; near Colonia Tovar (n).

138β. *Asplenium claussenii* Hieron.; YU. 4/2/57 [1/?] (s).

139. *Asplenium ruizianum* Klotzsch; MO, YU. [3/20]; 4,000 ft.; a few mi. S and SW of Colonia [Tovar] (n).

139β. *Asplenium ruizianum* Klotzsch; US, YU. [2/18] (s).

139γ. *Asplenium claussenii* Hieron.; YU. 25/1/55 [1/1] (s).

140. *Asplenium cirrhatum* Rich. ex Willd.; MO, YU. Mixed with *A. radicans* L. at YU. [5/23]; 7,000 ft.; seaside of mountains N of Colonia [Tovar] (n).
141. *Asplenium auritum* Sw. var. *obtusum* Kunze ex Mett.; MO. [2/?]; 4,000 ft.; a few mi. SW of Colonia Tovar (n).
142. *Asplenium monodon* Liebm.?; MO, YU. [6/20]; 6,000 ft.; Colonia Tovar (n).

ad 142. *Asplenium monodon* Liebm.?; YU. [4/?] (s).

142β. *Asplenium monodon* Liebm.; YU. [2/1] (s).
143. *Asplenium abscissum* Willd.; MO, YU. [9/20]; 6,400 ft.; Colonia Tovar (n).
143. *Asplenium oligophyllum* Kaulf.; MO.
143β. *Asplenium abscissum* Willd.; MO, YU. 4/10/54 [1/13] (s).
143γ. *Asplenium melanopus* Sodiro; YU. 19/12/54 [1/1] (s).
144. *Asplenium auriculatum* Sw., vel aff.; MO—2, YU. [11/22]; 6,000–7,000 ft.; Colonia Tovar (n).
145. *Asplenium alatum* Humb. & Bonpl. ex Willd.; MO, US, YU. [6/20]; 6,500 ft.; Colonia Tovar (n).
146. *Diplazium diplazioides* (Klotzsch & Karsten ex Klotzsch) Alston; YU. 28/9/55 [1/2]; 6,500 ft.; seaside of mountains N of Colonia [Tovar] (n).
147. *Diplazium hians* Kunze ex Klotzsch; US, YU—2. 28/6/54 [1/9]; 6,000 ft.; Colonia Tovar (n).
148. *Diplazium hians* Kunze ex Klotzsch; MO, YU—2. [2/5]; 5,600 ft.; Tuy River valley below Colonia [Tovar], seaside of mountains (n).
149. *Diplazium diplazioides* (Klotzsch & Karsten ex Klotzsch) Alston; MO, US, YU. [5/9]; 7,000–8,000 ft.; highest mountains around Colonia [Tovar] (n).
150. *Diplazium* aff. *striatum* (L.) C. Presl; MO, US, YU. [3/13]; 4,000 ft.; San Carlos River valley, a few mi. SW of Colonia [Tovar] (n).
151. *Diplazium mutilum* Kunze; MO, US, YU. [3/11]; 4,500 ft.; a few mi. S and SW of Colonia [Tovar] (n).
152. *Diplazium centripetale* (Baker) Maxon, vel aff.; MO, US, YU. 28/9/54 [1/10]; 6,000 ft.; seaside of mountains N of Colonia [Tovar] (n).
153. *Diplazium celtidifolium* Kunze; MO, US—3, YU. [5/20]; 6,000–7,000 ft.; around Colonia Tovar (n).

154. *Diplazium plantaginifolium* (L.) Urban; MO, US—2, YU. 29/8/54 [1/26]; 5,000–6,000 ft.; Tuy River valley below Colonia [Tovar] (n).
155. *Asplenium serra* Langsd. & Fischer; MO, YU—3. [9/20]; 7,000 ft.; around Colonia Tovar (n).
156. *Asplenium lividum* Mett. ex Kuhn; ISOTYPES, MO, US. Cited by Morton & Lellinger (1966). 25/10/54 [1/17]; 4,000 ft.; San Carlos River valley (n).
157. *Asplenium praemorsum* Sw.; MO, YU. [9/21]; 4,000–7,000 ft.; around Colonia Tovar, also 15 mi. W of Caracas (n).

157β. *Asplenium praemorsum* Sw.; YU. 27/2/57 [1/1] (s).

157?. *Asplenium praemorsum* Sw.; YU. [2/?].

158. *Thelypteris* (*Amauropelta*) *pilosohispida* (Hook.) Alston; GH, MO, YU—2. [9/20]; 6,000–7,000 ft.; Colonia Tovar (n).
159. *Thelypteris* (*Amauropelta*) *diplazioides* (Moritz ex Mett.) Ching; B, CU, GH—2, MO, US, YU—2. [3/16]; 5,500–6,000 ft.; seaside of mountains N of Colonia Tovar (n).
160. *Didymochlaena truncatula* (Sw.) J. Smith; MO, YU—3. [12/18]; 6,000–7,000 ft.; Colonia Tovar, also seaside of mountains N of Colonia Tovar (n).
161. *Nephrolepis occidentalis* Kunze; MO—2, YU. [2/22]; 3,000–4,000 ft.; a few mi. S of Colonia Tovar, also La Victoria (n). "Plant annual from tubers" (s).
162. *Nephrolepis pendula* (Raddi) J. Smith; MO—2, YU—2. [5/21]; 4,000–6,000 ft.; a few mi. S of Colonia [Tovar], also mountains N of Caracas (n).

162β. *Nephrolepis pendula* (Raddi) J. Smith, YU. [?/1].

163. *Athyrium skinneri* (Baker) C. Chr.; YU. 25/1/55 [1/1]; 3,000 ft.; Piedernales near Güigüe (n).
164. *Tectaria heracleifolia* (Willd.) L. Underw.; MO, US, YU. [5/9]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).

164β. *Tectaria heracleifolia* (Willd.) L. Underw.; YU. [2/3].

165. *Tectaria incisa* Cav., vel aff.; MO, YU—3. [6/17]; 4,000 ft.; a few mi. SW of Colonia Tovar (n).

165 additional. *Tectaria trifoliata* (L.) Cav.; YU. 12/12/56 [1/1] (s).

165β. *Tectaria incisa* Cav.; YU. 22/4/58 [1/1]; 4,000 ft.; seaside of mountains N of Petaquire (s).

166. *Tectaria incisa* Cav.; YU. [3/1]; 2,000–4,000 ft.; a few mi. SW of Colonia Tovar (n).
167. *Hemidictyum marginatum* (L.) C. Presl; MO, YU—2. 7/3/57 [1/?]; 3,000 ft.; seaside of mountain range between Valencia and San Estevan (n).
168. *Dryopteris patula* (Sw.) L. Underw.; MO—2, US, YU—2. [3/34]; 7,000 ft.; a few mi. W of Colonia Tovar (n).
169. *Dryopteris patula* (Sw.) L. Underw.; YU. 21/10/54 [1/2]; 3,200 ft.; Maya River valley, a few mi. S of Colonia Tovar (n).
170. *Arachniodes denticulata* (Sw.) Ching; MO. [4/?]; 7,000–8,000 ft.; highest mountains around Colonia Tovar (n).
171. *Polystichum* sp., aff. *polyphyllum* (C. Presl) C. Presl; US; mixed with *Polypodium* sp. [3/?]; 8,200 ft.; highest mountains E of Colonia [Tovar], in an open glade (n).
172. *Polystichum muricatum* (L.) Fée; US—2. [2/?]; 6,500 ft.; Colonia Tovar (n).
173. *Polystichum* sp.; YU; cited by Eaton (1861) as *Aspidium moritzianum* Klotzsch [possibly *P. muricatum* (L.) Fée]. [2/?]; 6,500 ft.; Colonia Tovar (n).
174. *Polystichum muricatum* (L.) Fée; US. [2/?]; 7,000 ft.; Colonia Tovar (n).
175. *Polystichum platyphyllum* (Willd.) C. Presl; YU; cited by Eaton (1861) as *Phegopteris platyphylla* (Willd.) Mett. [3/?]; 6,500 ft.; Colonia Tovar (n).
176. *Thelypteris* (*Amauropelta*) *concinna* (Willd.) Ching, vel aff.; CU, G, GH, MO, US. [2/?]; 2,500–3,000 ft.; Biscaina and Hacienda Carisal S of Colonia Tovar (n).
177. *Thelypteris* (*Amauropelta*) *opposita* (Vahl) Ching; MO, US, YU. [2/7]; 3,200 ft.; Caracas (n).
178. *Thelypteris* (*Amauropelta*) *pilosula* (Mett.) R. Tryon; GH, MO, US, YU. [3/15]; 7,000 ft.; Colonia Tovar (n).
179. *Thelypteris* (*Amauropelta*) *concinna* (Willd.) Ching; MO, YU—3. [2/20]; 7,000 ft.; a few mi. W of Colonia Tovar (n).

179. *Thelypteris* (*Amauropelta*) *oligocarpa* (Humb. & Bonpl. ex Willd.) Ching; MO.

180. *Thelypteris* (*Amauropelta*) *pilosula* (Mett.) R. Tryon; GH, MO, YU. [9/16]; 6,000–6,500 ft.; Colonia Tovar (n).
181. *Thelypteris* (*Amauropelta*) *scalaris* (Christ) Alston; GH, MO, US. [3/7]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).

181. *Thelypteris* (*Amauropelta*) *oligocarpa* (Humb. & Bonpl. ex Willd.) Ching; YU.

182. *Thelypteris* (*Amauropelta*) *opposita* (Vahl) Ching, vel aff.; MO, US, YU. [4/13]; 2,000–4,000 ft.; lower valleys S of Colonia [Tovar], also between Caracas and La Guayra (n).
183. *Thelypteris* (*Amauropelta*) *pilosula* (Mett.) R. Tryon; YU. 24/6/55 [1/1]; 8,000 ft.; highest mountains E of Colonia Tovar (n).
184. *Thelypteris* (*Amauropelta*) *pilosula* (Mett.) R. Tryon; YU. 13/10/54 [1/1]; 6,500 ft.; San Carlos River valley near Colonia [Tovar] (n).
185. *Thelypteris* (*Amauropelta*) *rudis* (Kunze) Proctor & *T. concinna* (Willd.) Ching; MO [*T. rudis* at US]. [4/13]; 5,800 ft.; a few mi. S of Colonia Tovar in wet places of savannah (n).

ad 185. *Thelypteris* (*Amauropelta*) *rudis* (Kunze) Proctor; YU. 1/6/54 [1/?] (s).

185. *Thelypteris* (*Amauropelta*) *proctorii* A. R. Smith & Lellinger?; YU.

186. *Thelypteris* (*Amauropelta*) *deflexa* (C. Presl) R. Tryon; B, G, GH, MO—3, P, YU. [3/20]; 7,000 ft.; a few mi. W of Colonia Tovar (n).
187. *Thelypteris* (*Amauropelta*) *rudis* (Kunze) Proctor; YU—2. 27/8/55 [1/4]; 6,500 ft.; a few mi. W of Colonia Tovar (n).

187. *Thelypteris* (*Amauropelta*) *cheilanthoides* (Kunze) Proctor; GH.

187. *Thelypteris* (*Amauropelta*) *pachyrhachis* (Kunze ex Mett.) Ching var. *pachyrhachis*; GH.

188. *Thelypteris* (*Cyclosorus*) *grandis* A. R. Smith var. *aequatorialis* (C. Chr.) A. R. Smith; MO, YU—2. [4/9]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).
189. *Thelypteris* (*Cyclosorus*) *patens* (Sw.) Small var. *patens*; MO, YU. [3/10]; 3,000 ft.; river valleys near Caracas, also Biscaina S of Colonia [Tovar] (n).
190. *Thelypteris* (*Cyclosorus*) *patens* (Sw.) Small var. *scabriuscula* (C. Presl) A. R. Smith; MO, YU—2.

25/10/54 [1/6]; 3,600 ft.; a few mi. SW of Colonia Tovar (n).

191. *Thelypteris* (*Cyclosorus*) *hispidula* (Decne.) Reed; YU. [3/4]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).
192. *Thelypteris* (*Cyclosorus*) *patens* (Sw.) Small var. *patens*; MO, YU. 20/2/54 [1/6]; 3,200 ft.; near Caracas (n).
193. *Thelypteris* (*Goniopteris*) *gemmulifera* (Hieron.) A. R. Smith; GH, MO, NY, YU. [2/3]; 3,000 ft.; a few mi. S of Colonia [Tovar], also seaside of mountains between Maracai and Choroni (n).

193γ. *Thelypteris* (*Goniopteris*) *gemmulifera* (Hieron.) A. R. Smith; YU. [3/6] (s).

194. *Ctenitis nigrovenia* (Christ) Copel.; MO, US, YU. [3/16]; 4,000 ft.; a few mi. S and SW of Colonia Tovar (n).
195. *Ctenitis submarginalis* (Langsd. & Fischer) Ching; YU. [3/1]; 3,200 ft.; Maya River, a few mi. S of Colonia [Tovar] (n).
196. *Thelypteris* (*Goniopteris*) *tetragona* (Sw.) Small; GH, MO, YU. [3/9]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).
197. *Ctenitis submarginalis* (Langsd. & Fischer) Ching; MO, US, YU—2. [2/16]; 3,200 ft.; valley of Maya, a few mi. S of Colonia [Tovar] (n).
198. *Stigmatopteris nephrodioides* (Klotzsch) C. Chr.; MO, US, YU—2. 29/8/54 [1/30]; 5,600 ft.; River Tuy below Colonia Tovar (n).
199. *Thelypteris* (*Goniopteris*) *poiteana* (Bory) Proctor; GH, MO, YU. [2/6]; 2,000 ft.; Piedernales, also between Caracas and La Guayra (n).
200. *Thelypteris* (*Goniopteris*) *pennata* (Poiret in Lam.) C. Morton; YU. 3,000–5,000 ft.; River Tuy below Colonia Tovar, also between Caracas and La Guayra (n); [2/2] (s).
201. *Thelypteris* (*Goniopteris*) *asterothrix* (Fée) Proctor; GH, MO—2, YU. 19/12/54 [1/22]; 3,200 ft.; Maya River a few mi. S of Colonia Tovar (n).
202. *Ctenitis subincisa* (Willd.) Ching; MO—3, YU—3. [8/20]; 6,000 ft.; Colonia Tovar (n).
203. *Ctenitis sloanei* (Sprengel) C. Morton; YU—2. 5/1/55 [1/1]; Piedernales near Güigüe (n).
204. *Ctenitis ampla* (Humb. & Bonpl. ex Willd.) Ching; MO, US—2, YU. [4/6]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).
205. *Lastreopsis effusa* (Sw.) Tindale subsp. *divergens* (Willd.) Tindale; MO, YU—2. [3/20]; 3,000–4,000 ft.; a few mi. SW of Colonia Tovar (n).
206. *Thelypteris* (*Amauropelta*) *pteroidea* (Klotzsch) R. Tryon; CU, GH, MO, US, YU—3. [5/12]; 7,500 ft.; 9 mi. E of Colonia Tovar (n).
207. *Grammitis phlegmaria* (J. Smith) Proctor; YU. [2/4] 6/5/58; 7,000–8,000 ft.; Colonia Tovar (n).
208. *Grammitis alfarii* (J. D. Smith) C. Morton; MO, YU; these are ISOSYNTYPES of *Polypodium oligosorum* Mett. ex Kuhn, Linnaea 36: 132. 1869 (non Klotzsch, 1847). [4/21]; 7,000–8,000 ft.; highest mountains E of Colonia Tovar, also between Maracai and Choroni (n). Specimens at MO and YU mixed with *G. senilis* (Fée) C. Morton.
209. *Grammitis senilis* (Fée) C. Morton; MO, US, YU, cited by Copeland (1955) as *Ctenopteris senilis* (Fée) Copel. [9/20]; 8,000 ft.; highest mountains around Colonia Tovar (n).
210. *Grammitis cultrata* (Willd.) Proctor; US, YU. [9/20]; 7,000–8,000 ft.; highest mountains around Colonia Tovar (n).
211. *Grammitis truncicola* (Klotzsch) C. Morton; MO, US—2, YU. [13/20]; 7,000–8,000 ft.; highest mountains around Colonia Tovar and W to Valencia (n).

211β. *Grammitis* sp.; YU; cited by Eaton (1861) as *Polypodium truncicola* Klotzsch.

211, pt. *Grammitis trichomanoides* (Sw.) Ching; US.

212. *Grammitis concinna* A. R. Smith, nom. nov.; GH, MO, YU; ISOTYPES of *Polypodium concinnum* Mett. ex Kuhn, Linnaea 36: 132. 1869 (non Willd., 1810). 25/6/54 [1/8]; 7,500 ft.; high mountains E of Colonia Tovar (n).
213. *Grammitis chrysleri* (Copel.) Proctor; MO, US, YU. [10/20]; 6,500 ft.; Colonia Tovar (n).

213β. *Grammitis asplenifolia* (L.) Proctor; YU. 6/5/58 [1/8] (s).

214. *Polypodium moritzianum* Link; MO, US, YU—2. [9/30]; 6,000–7,000 ft.; Colonia Tovar (n).
215. *Grammitis fendleri* (Copel.) Lellinger; MO, US, YU; these are ISOSYNTYPES of *Polypodium radicale* Moritz ex Hieron., Bot. Jahrb. Syst. 34: 511. 1904 (non Baker, 1867). Cited by Copeland (1955). [7/20]; 6,000–8,000 ft.; Colonia Tovar (n).
216. *Grammitis longisetulosa* (Copel.) C. Morton; MO, US, YU. [3/20]; 6,000–7,000 ft.; Colonia Tovar (n).
217. *Grammitis firma* (J. Smith) C. Morton; MO, YU. [6/20]; 6,000–7,000 ft.; Colonia Tovar (n).
218. *Grammitis apiculata* (Kunze ex Klotzsch) Seymour; MO, US, YU; cited by Copeland (1955) as *Ctenopteris apiculata* (Kunze) Copel. [9/20]; 6,000–7,000 ft.; Colonia Tovar (n).
219. *Grammitis xiphopteroides* (Liebm.) A. R. Smith; MO, YU; cited by Copeland (1955) as *Ctenopteris pilosissima* (Mart. & Gal.) Copel. [14/20]; 6,000–8,000 ft.; Colonia Tovar (n).
220. *Polypodium consimile* Mett. var. *consimile*; B, GH, MO, US, YU; cited by Evans (1969). [6/20]; 6,500 ft.; Colonia Tovar (n).

220β. *Polypodium consimile* Mett. var. *consimile*; GH, MO, US, YU; cited by Evans (1969).

221. *Polypodium eurybasis* C. Chr. var. *eurybasis*; MO, YU; det. ME at MO. At YU there are also specimens of *P. plumula* Humb. & Bonpl. ex Willd. and *P. dispersum* A. M. Evans on the same sheet. [12/20]; 6,000–8,000 ft.; Colonia Tovar (n).

221β. *Polypodium eurybasis* C. Chr.; YU. [8/13] (s).

221γ. *Polypodium camptophyllarium* Fée var. *lachniferum* (Hieron.) A. M. Evans; YU. 19/9/55 [1/1] (s).

221δ. *Polypodium* sp.; YU; cited by Eaton (1861) as *P. paradiseae* Langsd. & Fischer.

222. *Niphidium mortonianum* Lellinger; MO, YU; det. DL. [6/18]; 6,000–8,000 ft.; Colonia Tovar (n).
223. *Niphidium crassifolium* (L.) Lellinger; MO, YU; det. DL. [2/11]; 3,500–4,000 ft.; a few mi. SW of Colonia Tovar (n).
224. *Campyloneurum angustifolium* (Sw.) Fée; YU; det. DL. 5/6/55 [1/5]; 7,000–8,000 ft.; highest mountains E of Colonia Tovar, also between Maracai and Choroni (n).

224. *Campyloneurum chlorolepis* Alston; YU. 29/1/57 [1/1] (s).

225. *Campyloneurum chlorolepis* Alston; MO, YU. 3/7/55 [1/6]; 5,000 ft.; a few mi. S of Colonia Tovar (n).
226. *Campyloneurum amphostenon* (Kunze ex Klotzsch)

Fée; MO, YU. [13/20]; 7,000–8,000 ft.; a few mi. W of Colonia Tovar (n).

ad 226. *Campyloneurum amphostenon* (Kunze ex Klotzsch) Fée; YU; det. DL. [2/1]; highest mountains (s).

227. *Campyloneurum phyllitidis* (L.) C. Presl; MO, YU. [6/21]; 2,000–4,000 ft.; a few mi. SW of Colonia Tovar, also between Caracas and La Guayra, Piedernales (n).

228. *Campyloneurum chrysopodum* (Klotzsch) Fée; det. DL; MO—2, YU; these are ISOTYPES of *Campyloneurum fendleri* T. Moore, Ind. Fil. 224. 1861. 5/10/54 [1/19]; 5,500 ft.; seaside of mountains north of Colonia Tovar (n).

228β. *Campyloneurum chrysopodum* (Klotzsch) Fée; det. DL; MO, YU. 7/3/57 [1/6] (s).

229. *Campyloneurum repens* (Aubl.) C. Presl; MO, YU; det. DL. [2/10]; 5,500 ft.; seaside of mountains N of Colonia Tovar (n).

230. *Campyloneurum repens* (Aubl.) C. Presl; MO, YU; det. DL. [5/20]; 6,000 ft.; seaside of mountains N of Colonia Tovar (n).

231. *Campyloneurum decurrens* (Raddi) C. Presl; YU; det. DL. [3/4]; 5,000 ft.; seaside of mountains N of Colonia Tovar (n).

232. *Thelypteris* (*Meniscium*) *salzmannii* (Fée) C. Morton; GH, K, MO, YU—2; cited by Maxon & Morton (1938) as *Dryopteris ensiformis* C. Chr., in part [= *Thelypteris ensiformis* (C. Chr.) R. Tryon]. [2/14]; 4,000 ft.; Piedernales, also seaside of mountains between Valencia and San Estevan (n). One collection at YU contains both species.

232β. *Thelypteris* (*Meniscium*) *arborescens* (Humb. & Bonpl. ex Willd.) C. Morton; YU. [?/1].

233. *Phanerophlebia juglandifolia* (Humb. & Bonpl. ex Willd.) J. Smith; US, YU. [5/23]; 5,500 ft.; Tuy River valley below Colonia Tovar (n).

234. *Polypodium fraxinifolium* Jacq.; YU. 18/10/54 [1/1]; 7,000 ft.; a few mi. W of Colonia Tovar (n).

235. *Polypodium fraxinifolium* Jacq.; MO, YU. 24/6/55 [1/20]; 7,000 ft.; high mountains around Colonia Tovar (n).

236. *Polypodium fraxinifolium* Jacq.; YU; cited by Eaton (1861). 28/9/55 [1/?]; 7,000 ft.; seaside of mountains N of Colonia Tovar (n).

237. *Polypodium* aff. *fraxinifolium* Jacq.; YU. With acicular, spreading rhizome scales. 19/12/54 [1/3]; 6,000 ft. a few mi. S of Colonia Tovar (n). "Rhizome very different from no. 236" (s).

238. *Polypodium dissimile* L.; YU. [2/3]; 4,000–5,000 ft.; seaside of mountain range between Maracai and Choroni (n).

238β. *Polypodium dissimile* L.; YU. [?/1]. Mounted on same sheet as 238.

239. *Polypodium* sp.; YU; cited by Eaton (1861) as *P. latipes* Langsd. & Fischer. 15/7/54 [1/?]; 4,000 ft.; a few mi. SW of Colonia Tovar (n).

240. *Polypodium sessilifolium* Desv.; MO, YU. [6/10]; 7,000–8,000 ft.; high mountains around Colonia Tovar (n).

241. *Polypodium* (*Phlebodium*) *pseudoaureum* Cav.; MO, YU—2. [10/18]; 5,000–7,000 ft.; a few mi. S and SW of Colonia Tovar (n).

242. *Polypodium fuscopetiolatum* A. R. Smith; MO—2, YU—2. [2/23]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).

243. *Polypodium funckii* Mett.; US—2, YU. [2/14]; 8,000 ft.; highest mountains E of Colonia Tovar (n).

243?. *Polypodium* sp.; YU; cited by Eaton (1861) as *P. loriceum* L.

244. *Polypodium lasiopus* Klotzsch; MO, US, YU. [10/21]; 6,000–7,000 ft.; a few mi. S of Colonia Tovar (n).

245. *Polypodium remotum* Desv.; MO, US, YU. [6/17]; 6,200 ft.; Colonia Tovar (n).

246. *Polypodium buchtienii* Christ & Rosenstock; YU. [2/4]; 7,000–8,000 ft.; high mountains around Colonia Tovar (n).

247. *Polypodium steirolepis* C. Chr.; MO, NY, US, YU. ISOTYPES of *P. nigripes* Hook., Sp. Fil. 5: 17. 1863 (non Hassk., 1844). [5/17]; 3,500 ft.; a few mi. S and SW of Colonia Tovar (n).

248. *Microgramma vacciniifolia* (Langsd. & Fischer) Copel.; MO, YU. [2/6]; 1,000 ft.; seaside of mountains near San Estevan, also between Caracas and La Guayra (n).

249. *Pleopeltis macrocarpa* (Bory ex Willd.) Kaulf.; YU. 27/8/55 [1/4]; 6,500 ft.; a few mi. W of Colonia Tovar (n).

250. *Pleopeltis macrocarpa* (Bory ex Willd.) Kaulf.; MO, YU. [14/23]; 7,000 ft.; Colonia Tovar (n).

251. ×*Pleopodium leucosporum* (Klotzsch) Mickel & Beitel [*Pleopeltis macrocarpa* (Bory ex Willd.) Kaulf. × *Polypodium thyssanolepis* A. Braun ex Klotzsch]; MO, US, YU. 23/2/54 [1/?]; 4,000 ft.; mountains N of Caracas (n).

252. *Polypodium thyssanolepis* A. Braun ex Klotzsch; MO, YU. [4/20]; 3,000–4,000 ft.; valley of Macarao W of Caracas (n).

253. *Polypodium polypodioides* (L.) Watt var. *burchellii* (Baker) Weath.; MO, YU. [6/20]; 3,000–4,000 ft.; a few mi. S and SW of Colonia Tovar (n).

254. *Polypodium ursipes* Moritz ex C. Chr.; MO, US; these are ISOSYNTYPES of *P. ambiguum* Mett. ex Kuhn, Linnaea 36: 134. 1869 (non Desv., 1827). [3/?]; 8,000 ft.; highest mountains E of Colonia Tovar (n).

255. *Grammitis jamesonii* (Hook.) C. Morton; US, YU. 7,000–8,000 ft.; Colonia Tovar (n); [5/20] (s). On same sheet as *356* at YU.

256. *Grammitis leptopoda* (C. H. Wright) Copel.; MO, US. [2/?]; 7,000 ft.; Colonia Tovar (n).

257. *Grammitis jungermannioides* (Klotzsch) Ching; YU; cited by Eaton (1861) as *Polypodium jungermannioides* Klotzsch. [2/?]; 6,800 ft.; Colonia Tovar (n).

258. *Vittaria graminifolia* Kaulf.; MO, YU. [9/20]; 6,700 ft.; Colonia Tovar (n).

258. *Selaginella viticulosa* Klotzsch; NY; cited by Alston et al. (1981); erroneous citation?

259. *Vittaria moritziana* Mett. + *V. stipitata* Kunze; MO, YU. [6/19]; 6,000–7,000 ft.; Colonia Tovar (n).

259β. *Vittaria gardneriana* Fée; MO, YU. 6,000 ft. (n); [2/17] (s).

260. *Vittaria remota* Fée; MO, YU. [2/20]; 7,000 ft.; Colonia Tovar (n).

261. *Polybotrya serratifolia* (Fée) Klotzsch; MO—2, YU; det. RM. [5/17]; 6,000 ft.; Colonia Tovar (n).

262. *Polybotrya canaliculata* Klotzsch; MO—2, YU—

3; det. RM. [2/10 + 9]; 5,000 ft.; seaside of mountain range opposite the Colony [Tovar] (n).

263. *Elaphoglossum peltatum* (Sw.) Urban forma *flabellatum* (Humb. & Bonpl. ex Willd.) Mickel; MO, YU. [4/19]; 6,000 ft.; River Tuy below Colony (n).
264. *Elaphoglossum erinaceum* (Fée) T. Moore; MO, YU; det. JM. [6/5]; 5,000–6,000 ft.; Tuy valley below Colonia [Tovar] (n).
265. *Elaphoglossum eximium* (Mett.) Christ; GH, MO—2, PH, YU; these are ISOSYNTYPES of *Acrostichum reichenbachii* Moritz ex Kuhn, Linnaea 36: 42. 1869. [3/20]; 7,200 ft.; headwaters of San Carlos River (n).
266. *Elaphoglossum moritzianum* (Klotzsch) T. Moore; GH, MO, NY, PH, US, YU; det. JM. [6/20]; 5,900 ft.; valley of the Tuy River, below Colonia [Tovar] on rocks (n).
267. *Elaphoglossum piloselloides* (C. Presl) T. Moore; GH, MO, US, YU; det. JM. 19/9/55 [1/17]; 6,600 ft., San Carlos valley in a cave in rocks in the savannah (n).
268. *Elaphoglossum hieracioides* Mickel; HOLOTYPE, US; ISOTYPES, GH, MO, YU. [9/20]; 6,500 ft.; San Carlos valley (n).
269. *Elaphoglossum meridense* (Klotzsch) T. Moore; MO, NY, YU; det. JM. [9/20]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).

269β. *Elaphoglossum deorsum* (Karsten) Vareschi; MO; det. JM.

270. *Elaphoglossum bellermannianum* (Klotzsch) T. Moore; MO, NY, US, YU; det. JM. [7/21]; 6,500–7,000 ft.; mountain range S of Colonia [Tovar].
271. *Elaphoglossum cuspidatum* (Willd.) T. Moore; MO, NY, YU; det. JM. [4/20]; 6,300 ft.; mountains S of Colonia [Tovar] (n).
272. *Elaphoglossum tenuiculum* (Fée) T. Moore; P; this is the HOLOTYPE of *Acrostichum tenuiculum* Fée, Mém. Fam. Foug. 10: 6, t. 2, f. 2. 1865. ISOTYPE, YU. [2/18]; 6,600 ft.; 7 mi. SW of Colonia [Tovar] between rocks in savannahs (n).
273. *Elaphoglossum tectum* (Humb. & Bonpl. ex Willd.) T. Moore; MO, YU; det. JM. [5/23]; 6,500 ft.; Colonia Tovar (n).

ad 273. *Elaphoglossum tectum* (Humb. & Bonpl. ex Willd.) T. Moore; YU. 3/7/55 [1/1] (s).

274. *Elaphoglossum tectum* (Humb. & Bonpl. ex Willd.) T. Moore; YU. 27/8/55 [1/3]; 6,600 ft.; 7 mi. SW of Colonia [Tovar] (n).
275. *Elaphoglossum succubus* Mickel; HOLOTYPE, NY; ISOTYPES, MO, US. [5/21]; 6,000 ft.; Maya valley near Colonia [Tovar] (n).

275α. *Elaphoglossum affine* (Mart. & Gal.) T. Moore; MO, not seen; cited by Mickel in Smith (1985).

276. *Elaphoglossum huacssaro* (Ruiz) Christ; MO, US; det. JM. [3/?]; 6,000 ft.; mountain range S of Colonia [Tovar], in wet ground full of springs (n).
277. *Elaphoglossum* sp.; YU; cited by Eaton (1861) as *Acrostichum leptophyllum* Fée. 23/8/55 [1/?]; 7,500 ft.; Lagunassa, 12 mi. E of Colonia [Tovar] (n).
278. *Elaphoglossum chrysopogon* Mickel; MO, YU; det. JM. [2/14]; 6,900 ft.; 6 mi. SE of Colonia [Tovar] (n).
279. *Elaphoglossum chrysopogon* Mickel; HOLOTYPE, NY; ISOTYPE, NY. [3/8]; 6,700 ft.; Lagunita, 6 mi. SW of Colonia [Tovar], between rocks (n).
280. *Elaphoglossum burchellii* (Baker) C. Chr.; MO, YU; det. JM. these are ISOSYNTYPES of *Elaphoglossum xanthoneuron* Christ. [5/20]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).
281. *Elaphoglossum eximium* (Mett.) Christ; MO, YU; det. JM. [4/20]; 6,800 ft.; headwaters of San Carlos River, 3 mi. W of Colonia [Tovar].
282. *Elaphoglossum brachyneuron* (Fée) J. Smith; GH, MO, NY, US, YU; det. JM. [2/20]; 6,500 ft.; mountain range S of Colonia [Tovar] (n).
283. *Elaphoglossum ambiguum* (Mett. ex Christ) Alston; MO, US, YU—2; these are ISOTYPES of *Acrostichum ambiguum* Mett. ex Christ, Neue Denkschr. Allg. Schweiz. Ges. Gesammten Naturwiss. 36: 60. 1899. [5/20]; 6,400 ft.; Colonia [Tovar] (n).
284. *Elaphoglossum ambiguum* (Mett. ex Christ) Alston; MO, YU—2; det. JM. 28/9/54 [1/11]; 6,000–7,000 ft.; seaside of mountain range near Colonia [Tovar] (n).
285. *Elaphoglossum lingua* (C. Presl) Brackenr.; MO, US, YU; det. JM. [2/6]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).
286. *Elaphoglossum lloense* (Hook.) T. Moore; MO, NY, YU; det. JM. [7/20]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).
287. *Elaphoglossum macrophyllum* (Klotzsch) Christ; MO, NY, YU; det. JM. [3/12], 6,300 ft.; mountain range S of Colonia [Tovar].
288. *Elaphoglossum sellowianum* (Klotzsch ex Kuhn) C. Chr.; YU. [3/1]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).
289. Not located, most likely an *Elaphoglossum*. 27/9/55 [1/?]; 6,800 ft.; Colonia Tovar, plant easily drying, somewhat viscose, sticking to the paper, sterile (n).
290. *Elaphoglossum hoffmannii* (Mett. ex Kuhn) Christ; BM, MO, NY, US, YU; these are ISOSYNTYPES of *Acrostichum attenuatum* Kunze ex Kuhn, Linnaea 36: 56. 1869 (non Fée, 1853). [4/20]; 6,300 ft.; mountains S of Colonia [Tovar], on trunks of trees and upon the ground (n).
291. *Elaphoglossum sporadolepis* (Kunze ex Kuhn) C. Chr.; YU. 2/10/54 [1/1]; 6,300 ft.; mountains S of Colonia [Tovar] (n).
292. *Elaphoglossum tovarense* (Moritz ex Kuhn) T. Moore; BM, MO, NY, US, YU; these are ISOSYNTYPES of *Acrostichum tovarense* Moritz ex Kuhn, Linnaea 36: 60. 1869. [4/20]; 6,300 ft.; mountain range S of Colonia [Tovar], upon the ground (n).
293. *Elaphoglossum sporadolepis* (Kunze ex Kuhn) C. Chr.; MO—2, YU; these are ISOSYNTYPES of *Acrostichum corpulentum* Kunze ex Kuhn, Linnaea 36: 61. 1869. [3/20]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).

293. *Elaphoglossum andicola* (Fée) T. Moore; NY; cited by Mickel in Smith (1985).

294. *Elaphoglossum sporadolepis* (Kunze ex Kuhn) C. Chr.; MO, NY, US, YU; these are ISOLECTOTYPES of *Acrostichum sporadolepis* Kunze ex Kuhn, Linnaea 36: 59. 1869. [5/21]; 6,300 ft.; mountain range S of Colonia [Tovar] (n).

294, pt. *Elaphoglossum sporadolepis* (Kunze ex Kuhn) C. Chr.; B, YU; the former is the HOLOTYPE of *Acrostichum compactum* Mett. ex Kuhn, Linnaea 36: 59. 1869; cited by Mickel in Smith (1985).

295. *Elaphoglossum sellowianum* (Klotzsch ex Kuhn)

C. Chr.; US, YU; these are ISOSYNTYPES of *Acrostichum sellowianum* Klotzsch ex Kuhn, Linnaea 36: 52. 1869. [10/22]; 6,400 ft.; Colonia Tovar (n).

295α, pt. *Elaphoglossum tenuiculum* (Fée) T. Moore; MO, not seen; cited by Mickel in Smith (1985).

295β. *Elaphoglossum sellowianum* (Klotzsch ex Kuhn) Christ; YU; this is an ISOSYNTYPE of *Acrostichum sellowianum* Klotzsch ex Kuhn, Linnaea 36: 52. 1869. [4/16] (s).

296. *Elaphoglossum sporadolepis* (Kunze ex Kuhn) C. Chr.; MO, YU; these are ISOSYNTYPES of *Acrostichum sporadolepis* Kunze ex Kuhn, Linnaea 36: 59. 1869; det. JM. [3/8]; 6,300 ft.; mountains S of Colonia [Tovar].

297. *Pityrogramma trifoliata* (L.) R. Tryon; MO, YU. [2/19]; 3,000–4,000 ft.; warmer parts of river valleys, not far from the water (n).

298. *Pityrogramma calomelanos* (L.) Link; MO, US; these are ISOTYPES of *P. calomelanos* var. *venezuelae* Domin., Rozpr. Ceské Akad. Věd, Tř. 2, Vědy Mat. Přír., II. 51(18): 12. 1941. [2/?]; 3,000 ft.; between Caracas and La Guayra (n).

299. *Pityrogramma tartarea* (Cav.) Maxon; MO, YU—3. [10/20]; 6,300 ft., Colonia Tovar (n).

300. *Eriosorus flexuosus* (H.B.K.) Copel. var. *flexuosus*; G, GH, K, MO, P, US, YU; cited by A. Tryon (1970). [3/13]; 7,400 ft.; 12 mi. E of Colonia [Tovar] (n).

301. *Eriosorus hirtus* (H.B.K.) Copel. var. *hirtus*; B. BM, F, G, GH, K, MO—2, NY, YU—2; cited by A. Tryon (1970). [10/20]; 7,000 ft.; a few mi. W of Colonia [Tovar].

302. *Hemionitis rufa* (L.) Sw.; YU; cited by Eaton (1861) as *Gymnogramme rufa* Desv. 2,500 ft.; Piedernales, a little S of the lake of Valencia (n).

303. *Hemionitis palmata* L.; YU. [2/18]; 2,500–3,000 ft.; Piedernales, a little S of the lake of Valencia, [also] between La Guayra and Caracas (n).

304. *Antrophyum lineatum* (Sw.) Kaulf.; MO, YU. [12/20]; 6,000–7,000 ft.; Colonia Tovar (n).

305. *Antrophyum cajenense* (Desv.) Sprengel; MO, YU. Mixed on same sheet with *Antrophyum brasilianum* (Desv.) C. Chr. at YU. [3/23]; 6,000–7,000 ft.; Colonia Tovar, near Tuy River (n).

306. *Thelypteris* (*Amauropelta*) *aspidioides* (Willd.) R. Tryon; G, MO, US, YU. [4/13]; 5,600 ft.; Tuy River below Colonia [Tovar]; San Carlos River (n).

307. *Thelypteris* (*Amauropelta*) *rupestris* (Klotzsch) Reed; GH, MO, US. [2/?]; Colonia Tovar (n).

308. *Blechnum fragile* (Liebm.) C. Morton & Lellinger, vel aff.; MO. [3/?]; 7,800 ft.; 12 mi. E of Colonia [Tovar] (n).

309. *Blechnum divergens* (Kunze) Mett.; MO. [3/?]; 6,000–7,000 ft.; Colonia Tovar (n).

310. *Blechnum lehmannii* Hieron.; MO. [3/?]; 6,000–7,000 ft.; Colonia Tovar (n).

311. *Bolbitis serratifolia* (Mertens ex Kaulf.) Schott; BM, BR, G, K, MO, P, US, YU; cited by Hennipman (1977). [2/20]; 4,000 ft.; valley of San Carlos, SW of Colonia [Tovar] (n).

312. *Ophioglossum reticulatum* L.; MO. [3/?]; 6,500 ft.; several mi. SW of Colonia [Tovar].

313. *Lycopodium thyoides* Humb. & Bonpl. ex Willd.; MO, YU—2. [4/22]; 6,500–7,500 ft.; a few mi. S of Colonia Tovar (n).

314. *Lycopodium clavatum* L.; MO, YU. [4/12]; 7,000 ft.; a few mi. W of Colonia Tovar (n).

314β. *Lycopodium clavatum* L.; YU. 19/7/56 [1/2]; 7,000 ft. (s).

315. *Lycopodium alopecuroides* L.; YU. [2/17]; 6,000 ft.; a few mi. S of Colonia Tovar, wet places in the savannah (n).

316. *Lycopodium reflexum* Lam.; MO, YU. [7/20]; 7,000 ft.; a few mi. W of Colonia Tovar (n).

317. *Lycopodium acerosum* Sw.; YU. [2/7]; 3,500 ft.; valley a few mi. SW of Colonia Tovar (n).

318. *Lycopodium cernuum* L.; YU. [2/1]; 7,500 ft.; highest mountains E of Colonia Tovar (n).

319. *Lycopodium taxifolium* Sw.; MO, YU; det. BO. [6/17]; 6,500–8,000 ft.; around Colonia Tovar (n).

320. *Lycopodium myrsinites* Lam.; MO, YU; det. BO. [3/20]; 8,000 ft.; highest mountains E of Colonia Tovar (n).

321. *Selaginella pallescens* (C. Presl) Spring in Martius; MO, NY, YU. [4/22]; 2,000–4,000 ft.; valleys SW of Colonia Tovar, also La Victoria (n).

321β. *Selaginella pallescens* (C. Presl) Spring; YU. 23/8/56 [1/1]; 2,000 ft.; [La] Victoria (s).

322. *Selaginella viticulosa* Klotzsch; MO, YU. 16/8/55 [1/18]; 2,500 ft.; seaside of mountains between Caracas and La Guayra (n).

322. *Selaginella cavifolia* A. Braun; BM; this is an ISOSYNTYPE of *S. moritziana* var. *elongata* A. Braun, Ann. Sci. Nat. Bot., V. 3: 285. 1865; cited by Alston et al. (1981).

323. *Selaginella cavifolia* A. Braun; MO, YU; these are ISOSYNTYPES of *S. moritziana* var. *elongata* A. Braun, Ann. Sci. Nat. Bot., V. 3: 285. 1865. [4/17]; 7,000 ft.; high mountains around Colonia Tovar (n).

324. *Selaginella flagellata* Spring; BM, MO, YU; these are ISOSYNTYPES of *S. ambigua* A. Braun, Ann. Sci. Nat. Bot., V. 3: 286. 1865; cited by Alston et al. (1981). [2/22]; 2,300 ft.; La Victoria and Piedernales (n).

324, pt. *Selaginella cladorrhizans* A. Braun, Ann. Sci. Nat. Bot., V. 3: 282. 1865; SYNTYPES, B, BM, YU; cited by Alston et al. (1981). At YU, this species and *S. flagellata* are mixed on the same sheet.

325. *Plagiogyria semicordata* (C. Presl) Christ; MO, YU. 23/8/55 [1/18]; 8,000 ft.; highest mountains, 12 mi. E of Colonia [Tovar] (n).

326. *Asplenium oligophyllum* Kaulf.; MO, US, YU. 3,500 ft.; a few mi. SW of Colonia Tovar, river bottom (n); 17/5/55 [1/26] (s).

327. *Hymenophyllum* (*Sphaerocionium*) *trichophyllum* H.B.K.; GH; YU cited by Morton (1947). 25/8/56 [1/20]; 8,000 ft.; 10 mi. E of Colonia [Tovar], highest mountains (n); Lagunassa (s).

328. *Hymenophyllum* (*Sphaerocionium*) *lanatum* Fée; YU. 12/7/56 [1/8]; 7,500 ft.; a few mi. W of Colonia [Tovar] (n).

ad 328. *Hymenophyllum* (*Sphaerocionium*) *lanatum* Fée; YU. 12/7/56 [1/10]; high mountains, La Victoria pass (s).

329. *Trichomanes* (*Acarpacrium*) *polypodioides* L.; MO, US, YU—2. [2/20]; 6,500–7,000 ft.; seaside of mountains north of Colonia Tovar (n).

330. *Lastreopsis exculta* (Mett.) Tindale; MO. 28/6/56, 8/1/57 [2/?]; 6,000 ft.; Colonia Tovar (n).

331. *Asplenium salicifolium* L.; YU—2. 12/7/56 [1/?]; 6,000–7,000 ft.; Colonia Tovar (n).
331β. *Asplenium auriculatum* Sw.; YU. 22/4/58 [1/?] (s).
332. *Asplenium serra* Langsd. & Fischer; YU—2. [?/2]; 7,000–8,000 ft.; Colonia Tovar (n). "Has been mixed up with no. 155, but pinnae very different; also the meshes of veinlets in the scales of rhizome smaller" (s).
333. *Asplenium serra* Langsd. & Fischer; YU. 22/1/56 [1/3]; 7,000 ft.; seaside of mountains N of Colonia [Tovar] (n).
334. *Diplazium macrophyllum* Desv.; YU—2. [2/1]; 6,000 ft.; seaside of mountains N of Colonia [Tovar], also between Valencia and San Estevan (n).
335. *Lomariopsis fendleri* D. Eaton, Mem. Amer. Acad. Arts, n.s. 8: 195. 1861; SYNTYPES, YU—3 sheets, collected on two different dates; ISOSYNTYPE, K. [2/16]; 6,000 ft.; seaside of mountain range between Colonia [Tovar] and Chichiribichi (n).
ad 335. *Lomariopsis fendleri* D. Eaton; YU. 22/1/56 [1/?] (s).
336. *Bolbitis portoricensis* (Sprengel) Hennipman; MO, YU—2; cited by Hennipman (1977). One collection at YU mixed with juveniles of *Pteris altissima* Poiret in Lam. 29/1/57 [1/13]; 3,500 ft.; seaside of mountain range between Maracai and Choroni (n).
337. Not located, *Lycopodium* (n). 17/7/56 [1/?]; 7,500 ft.; high mountains E of Colonia Tovar, upon trees (n).
338. *Grammitis pilosissima* (Mart. & Gal.) C. Morton; YU. 12/7/56 [1/1]; 7,500 ft.; Colonia Tovar (n).
339. Not located, no data in notebook.
340. *Blechnum schomburgkii* (Klotzsch) C. Chr.; MO. [3/7]; 7,000–8,000 ft.; Petaquire mountains, also highest mountains E of Colonia [Tovar] (n).
341. *Polypodium fuscopetiolatum* A. R. Smith; YU. 26/5/54 [1/1]; 3,500 ft.; Biscaina, S of Colonia [Tovar] (n).
342. *Ophioglossum nudicaule* L. f.; MO. 5,000 ft.; a few mi. S of Colonia [Tovar], beneath low shrubs at margin of woods (n).
343. *Polypodium bolivari* Sota; YU. 3/9/56 [1/3]; 5,000 ft.; a few mi. S of Colonia Tovar (n); near Maya (s).
344. *Cyathea villosa* Willd.; B; this is the HOLOTYPE of *Alsophila vernicosa* Mett. ex Kuhn, Linnaea 36: 155. 1869; ISOTYPES, GH, MO, YU; cited by Barrington (1978) as *Trichipteris villosa* (Willd.) R. Tryon. 21/8/56 [1/6]; 5,800 ft.; a few mi. S of Colonia [Tovar], in savannahs (n).
345. Not located. 2/9/56; 6,000 ft.; Colonia Tovar (n).
346. Not located. 5,000 ft.; beneath low shrubs, margin of woods, Maya near Colonia [Tovar] (n).
347. *Lycopodium* cf. *pendulinum* Hook.; MO, YU. 21/8/56 [1/21]; 6,000 ft.; a few mi. S of Colonia Tovar in wet places in the savannah (n).
348. *Grammitis* cf. *senilis* (Fée) C. Morton; MO. [2/?]; 7,000 ft.; seaside of mountain range between Maracai and Choroni (n).
349. *Grammitis* aff. *subtilis* (Kunze ex Klotzsch) C. Morton; MO, YU. 12/12/56 [1/7]; 6,500 ft.; seaside of mountain range between Maracai and Choroni (n).
350. *Grammitis* sp.; YU; cited by Eaton (1861) as *Polypodium pendulum* Sw. 12/12/56; 6,500 ft.; seaside of mountain range between Maracai and Choroni (n).
351. *Grammitis asplenifolia* (L.) Proctor?; YU. Juvenile. 12/12/56 [1/1]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
352. *Polypodium triseriale* Sw.; YU. 25/1/55 [1/1]; 3,500 ft.; Piedernales near Güigüe (n).
353. *Polypodium loriceum* L.; MO, YU—2. [2/3]; 6,000 ft.; seaside of mountains between Maracai and Choroni (n).
354. *Microgramma reptans* (Cav.) A. R. Smith; MO, YU. [2/11] 2,500 ft.; seaside of mountains between Maracai and Choroni (n).
355. *Cochlidium rostratum* (Hook.) Maxon ex C. Chr.; MO. [2/?]; 6,000 ft.; in crossing the mountains from Maracai towards Choroni (n).
356. *Cochlidium serrulatum* (Sw.) L. E. Bishop; MO, YU. [2/20]; 6,000–7,000 ft.; seaside of mountains between Maracai and Choroni, and between Valencia and San Estevan (n).
357?. *Pityrogramma chrysoconia* (Desv.) Maxon ex Domin; YU. [4/?]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
358. *Eriosorus hirtus* (H.B.K.) Copel. var. *hirtus*; GH, YU; cited by A. Tryon (1970). [3/1]; 6,000–7,000 ft.; a few mi. W of Colonia [Tovar] (n).
359. *Eriosorus hispidulus* (Kunze) Vareschi var. *hispidulus*; K, YU; cited by A. Tryon (1970). 12/12/56 [1/3]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
360. *Thelypteris* (*Amauropelta*) *aspidioides* (Willd.) R. Tryon; YU. 12/12/56 [1/2]; 2,500 ft.; seaside of mountain range between Maracai and Choroni (n).
361. *Elaphoglossum peltatum* (Sw.) Urban; MO, YU. [3/11]; 7,000 ft.; seaside of mountain range between Maracai and Choroni (n).
362. *Elaphoglossum pusillum* (Mett. ex Kuhn) C. Chr.; GH, NY, PH; these are ISOSYNTYPES of *Acrostichum fraseri* Mett. ex Kuhn, Linnaea 36: 43. 1869. 12/12/56 [1/?]; 2,000 ft.; near Esmeralda above Choroni (n).
363. *Elaphoglossum crinitum* (L.) Christ; YU. [2/2]; 2,500 ft.; seaside of mountain range between Maracai and Choroni (n).
364. *Adiantum tetraphyllum* Humb. & Bonpl. ex Willd.; YU. 12/12/56 [1/3]; 2,000 ft.; seaside of mountain range between Maracai and Choroni (n).
364. *Elaphoglossum pusillum* (Mett. ex Kuhn) C. Chr.; MO; det. JM.
365. *Pteris altissima* Poiret in Lam.; YU. 12/12/56 [1/1]; 2,500 ft.; seaside of mountain range between Maracai and Choroni (n).
366. *Doryopteris sagittifolia* (Raddi) J. Smith; MO, YU, [2/19]; 2,500 ft.; seaside of mountain range between Maracai and Choroni (n).
367. *Asplenium cirrhatum* Rich. ex Willd.; YU. [2/1]; 4,000 ft.; seaside of mountain range between Maracai and Choroni (n).
368. *Asplenium tenerrimum* Mett. ex Kuhn, Linnaea 36: 97. 1869; ISOTYPES, MO, NY, US; cited by Morton & Lellinger (1966) as *A. cuspidatum* Lam. var. *tenerrimum* (Mett. ex Kuhn) C. Morton & Lellinger. 21/11/56 [1/?]; 2,300 ft.; near La Victoria (n).

369. *Diplazium expansum* Willd.; YU—2. 12/12/56 [1/1]; 4,000 ft.; seaside of mountain range between Maracai and Choroni (n).
370. *Nephrolepis rivularis* (Vahl) Mett. ex Krug; MO, YU. 29/1/57 [1/7]; 5,000 ft.; seaside of mountain range between Maracai and Choroni (n).
371. *Thelypteris* (*Steiropteris*) *praetervisa* (Kuhn) A. R. Smith; K, YU; these are ISOTYPES of *Aspidium praetervisum* Kuhn, Linnaea 36: 111. 1869; cited by Smith (1980). 12/12/56 [1/2]; 2,500 ft.; seaside of mountains between Maracai and Choroni (n).
372. *Thelypteris* (*Steiropteris*) *fendleri* (D. Eaton) Reed; YU—2; HOLOTYPE of *Aspidium fendleri* D. Eaton, Mem. Amer. Acad. Arts, n.s. 8: 210. 1861; ISOTYPES, B, GH, K; cited by Smith (1980). [2/9]; 2,500 ft.; seaside of mountains between Maracai and Choroni (n).
373. *Thelypteris* (*Steiropteris*) *decussata* (L.) Proctor var. *decussata*; MO, YU—2; cited by Smith (1980). [2/8]; 3,000 ft.; seaside of mountains between Choroni and Maracai, also between Valencia and San Estevan (n).
374. *Dennstaedtia obtusifolia* (Willd.) T. Moore; YU. 12/12/56 [1/4]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
375. *Saccoloma inaequale* (Kunze) Mett.; MO, YU—2. [2/9]; 5,000 ft.; seaside of mountain range between Maracai and Choroni (n).
376. *Saccoloma elegans* Kaulf.; YU. 12/12/56 [1/2]; 3,000 ft.; seaside of mountain range between Maracai and Choroni (n).
377. *Lindsaea stricta* (Sw.) Dryander var. *stricta*; B, BR, C, F, G, GH, GOET, K, MO, PH, US, YU; cited by Kramer (1957). [2/22]; 4,000 ft.; seaside of mountain range between Maracai and Choroni (n).
378. *Lindsaea lancea* (L.) Beddome var. *lancea*; MO, YU; this number cited by Kramer (1957) as this species and also as *L. stricta* (Sw.) Dryander var. *stricta*. 12/12/56 [1/18]; 4,500 ft.; seaside of mountain range between Maracai and Choroni (n).

378, pt. *Lindsaea stricta* (Sw.) Dryander var. *stricta*; YU. This sheet is, in part, juvenile material of some other species of *Lindsaea*.

379. = 63*β* (n & s), which is *Lindsaea klotzschiana* Moritz in Ettingshausen. Without locality data in notebook.
380. *Lindsaea stricta* (Sw.) Dryander var. *stricta*; cited by Kramer (1957). 12/12/56 [1/6]; 5,000 ft.; seaside of mountain range between Maracai and Choroni (n).
380. *Lindsaea klotzschiana* Moritz in Ettingshausen; YU. 12/12/56 [1/?]; 5,000 ft. (s).
381. *Grammitis taxifolia* (L.) Proctor; YU. 30/1/58 [1/1]; 6,500 ft.; seaside of mountains between Agua Blanca and Cumbote (n).
382. *Cyathea gibbosa* (Klotzsch) Domin; YU. 12/12/56 [1/1]; 5,000 ft.; seaside of mountain range between Maracai and Choroni (n).
383. *Cyathea senilis* (Klotzsch) Domin; YU—2. [2/3]; 6,500 ft.; seaside of mountain range between Maracai and Choroni and further west (n).
384. Not located. 29/1/57 [1/?]; 6,000 ft.; seaside of mountains between Maracai and Choroni (n).
385. *Cnemidaria horrida* (L.) C. Presl; MO, YU; cited by Stolze (1974). [3/13]; 2,000–3,000 ft.; seaside of mountain range between Maracai and Choroni, also between Valencia and San Estevan (n).
386. *Cnemidaria karsteniana* (Klotzsch) R. Tryon; MO; cited by Stolze (1974). [3/8]; 5,000 ft.; seaside of mountain range between Maracai and Choroni and further west (n).
387. *Hymenophyllum* (*Sphaerocionium*) *lanatum* Fée; GH, MO, YU; cited by Morton (1947). 12/12/56 [1/11]; 6,000 ft.; seaside of mountains between Maracai and Choroni (n).
388. *Trichomanes* (*Achomanes*) *crispum* L.; YU. [2/21]; 4,000–5,000 ft.; seaside of mountains between Maracai and Choroni (n).
388*β*. *Trichomanes* (*Achomanes*) sp., undescribed? (same as 389); YU. 29/1/57 [1/2] (s).
389. *Trichomanes* (*Achomanes*) sp., undescribed?; MO, YU. [3/10]; 5,000 ft.; seaside of mountains between Maracai and Choroni (n).
390. *Trichomanes* (*Neurophyllum*) *pinnatum* Hedwig; MO, YU. [2/11]; 4,000 ft.; seaside of mountains between Maracai and Choroni (n).
391. *Elaphoglossum glabellum* J. Smith; YU. [2/4]; 7,000 ft.; in crossing mountains from Maracai to Choroni (n).
392. Not located. 12/12/54 [1/?]; 6,500 ft.; Colonia Tovar (n).
393. *Hymenophyllum* (*Mecodium*) *apiculatum* Mett. ex Kuhn; YU. 12/12/56 [1/1]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
394. *Hymenophyllum* (*Mecodium*) *polyanthos* (Sw.) Sw.; YU. 12/12/56 [1/3]; 6,500 ft.; seaside of mountain range between Maracai and Choroni (n).
395. *Trichomanes* (*Lacosteopsis*) *capillaceum* L.; YU. 6,500 ft.; Colonia Tovar, on rocks near a rivulet (n); 4,000 ft.; (s).
396. *Schizaea elegans* (Vahl) Sw.; MO. 12/12/56 [1/?]; 4,500 ft.; seaside of mountain range between Maracai and Choroni (n).
397. *Selaginella diffusa* (C. Presl) Spring; MO, YU. 12/12/56 [1/12]; 4,000 ft.; seaside of mountain range between Maracai and Choroni (n).
398. *Lycopodium* (n), not located. 12/12/56 [1/?]; 5,000 ft.; seaside of mountain range between Maracai and Choroni (n).
399. *Lycopodium cernuum* L.; YU. 12/12/56 [1/3]; 5,500 ft.; seaside of mountains between Maracai and Choroni (n).
399*β*. *Lycopodium cernuum* L.; YU, mounted on same sheet as *399*. 12/12/56 [1/1]; 6,000 ft.; mountains between Maracai and Choroni on dry south side (s).
400. *Lycopodium thyoides* Humb. & Bonpl. ex Willd.; YU. 12/12/56 [1/1]; 6,500 ft.; seaside of mountains between Maracai and Choroni (n).
401. Not located. 6/1/57 [1/?]; highest mountains E of Colonia Tovar (n).
402. *Selaginella porphyrospora* A. Braun; YU. 12/12/56 [1/3]; 5,000 ft.; seaside of mountains between Maracai and Choroni (n).
403. *Selaginella flagellata* Spring; YU. 12/12/56 [1/4]; 3,000 ft.; seaside of mountains between Maracai and Choroni (n).
404. *Cheilanthes* sp.; YU; cited by Eaton (1861) as *Pellaea decomposita* Hook. [could be *C. marginata* H.B.K.]. 7/3/57 [1/?]; 3,500 ft.; seaside of

mountain range between Valencia and San Estevan (n).

405. *Athyrium filix-femina* (L.) Roth; MO, YU. 6/1/57 [1/22]; 8,000 ft.; 12 mi. E of Colonia Tovar, highest mountains (n).
406. *Grammitis moniliformis* (Lagasca ex Sw.) Kaulf.; YU; cited by Eaton (1861). 29/1/57 [1/?]; 7,000 ft.; seaside of mountains between Maracai and Choroni (n).
407. *Polypodium hygrometricum* Splitg.; YU. 28/1/57 [1/1]; 3,000 ft.; seaside of mountains between Maracai and Choroni (n).
408. *Bolbitis hemiotis* (Maxon) Ching; YU. 29/1/57 [1/5]; 4,000 ft.; seaside of mountains between Maracai and Choroni (n).
409. *Campyloneurum occultum* (Christ) L. D. Gómez; YU. 29/1/57 [1/3]; 6,000 ft.; seaside of mountains between Maracai and Choroni (n).
410. *Campyloneurum magnificum* T. Moore; YU—4 sheets, collected on two different dates; these are SYNTYPES of *Polypodium fendleri* D. Eaton, Mem. Amer. Acad. Arts, n.s. 8: 199. 1861; ISOSYNTYPES, MO—2. [2/13]; 4,000 ft.; seaside of mountains between Petaquire and the sea (n).
411. *Asplenium* sp.; YU; cited by Eaton (1861) as *A. salicifolium* L. 12/2/58 [1/?]; 4,000 ft.; seaside of mountains between Petaquire and Cariaca (n).
412. *Tectaria plantaginea* (Jacq.) Maxon var. *plantaginea*; MO, YU—2. 9/2/57 [1/18]; 4,000 ft.; seaside of mountains between Petaquire and the sea (n).
413. *Polypodium sessilifolium* Desv.; YU. 9/2/57 [1/2]; 5,000 ft.; seaside of mountains between Petaquire and the sea (n).
414. *Polypodium* aff. *fraxinifolium* Jacq.; YU. 29/1/57 [1/1]; 6,500 ft.; seaside of mountains between Maracai and Choroni (n).
415. *Polypodium triseriale* Sw.; YU. 29/1/57 [1/1]; 6,000 ft.; seaside of mountains between Maracai and Choroni (n).
416. *Thelypteris* (*Amauropelta*) *oligocarpa* (Humb. & Bonpl. ex Willd.) Ching; YU. 12/12/56 [1/1]; 2,500 ft.; seaside of mountain range between Maracai and Choroni (n).
417. *Polypodium* (*Phlebodium*) *aureum* L.; YU. [2/1]; 3,000 ft.; seaside of mountain range between Maracai and Choroni (n).
418. *Polypodium lasiopus* Klotzsch; YU. 29/1/57 [1/3]; 6,500 ft.; seaside of mountains between Maracai and Choroni (n).
419. *Microgramma tecta* (Kaulf.) Alston; MO, YU. [2/22]; 2,000 ft.; seaside of mountains between Petaquire and the sea (n).
420. *Microgramma lycopodioides* (L.) Copel.; MO, YU. [2/15]; 2,500 ft.; seaside of mountains between Maracai and Choroni (n).
421. *Pleopeltis percussa* (Cav.) Hook. & Grev.; MO, YU. [3/3]; 4,000 ft.; seaside of mountains between Maracai and Choroni (n).
422. *Polypodium sororium* Humb. & Bonpl. ex Willd.; MO, YU. 9/2/57 [1/6]; 8,000 ft.; highest mountains E of Colonia Tovar (n).
423. *Dicranoglossum furcatum* (L.) J. Smith; YU. 9/2/57 [1/2]; 3,000 ft.; seaside of coast range of mountains (n).
424. *Vittaria costata* Kunze; YU. 29/1/57 [1/1]; 5,500 ft.; seaside of mountain range between Maracai and Choroni (n).
425. *Anetium citrifolium* (L.) Splitg.; YU. 29/1/57 [1/2]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
426. *Olfersia cervina* (L.) Kunze; MO, YU—3. 9/2/57 [1/4]; 4,000 ft.; seaside of mountain range between Petaquire and Chichiribichi (n).
427. Not located. 29/1/57 [1/?]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
428. *Elaphoglossum herminieri* (Bory & Fée ex Fée) T. Moore; YU. 29/1/57 [1/1]; 3,500 ft.; seaside of mountain range between Maracai and Choroni (n).
429. *Elaphoglossum lingua* (C. Presl) Brackenr.; YU. 3,500 ft.; seaside of mountain range between Maracai and Choroni (n); 29/1/57 [1/2] (s).
430. *Elaphoglossum* sp.; YU; cited by Eaton (1861) as *Acrostichum apodum* Kaulf. 29/1/57 [1/?]; 3,500 ft.; seaside of mountain range between Maracai and Choroni (n).
431. *Hypolepis stuebelii* Hieron.; MO, YU. [3/4]; 3,000 ft.; seaside of mountain range between Petaquire and the sea, also farther west (n).
432. *Asplenium auriculatum* Sw.; YU. 29/1/57 [1/1]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
433. *Asplenium pteropus* Kaulf.; MO, YU. [2/8]; 5,000 ft.; seaside of mountain range between Petaquire and Choroni (n).
434. *Asplenium cirrhatum* Rich. ex Willd.; YU. 9/2/57 [1/3]; 5,000 ft.; seaside of mountain range between Petaquire and the sea (n).
435. *Diplazium pedatum* Klotzsch; YU. [2/1]; 5,000 ft.; seaside of mountain range between Maracai and Choroni and between Petaquire and the sea (n).

435β. *Diplazium pedatum* Klotzsch; YU. 12/12/56 [1/1] (s).

436. *Diplazium pedatum* Klotzsch; MO, YU. 29/1/57 [1/7]; 6,000 ft.; seaside of mountain range between Maracai and Choroni (n).
437. *Thelypteris* (*Amauropelta*) *diplazioides* (Moritz ex Mett.) Ching; YU. 26/1/57 [1/1]; 100 ft.; near Colombia N of Choroni (n).
438. *Thelypteris* (*Amauropelta*) *balbisii* (Sprengel) Ching; YU. 26/1/57 [1/1]; 200 ft.; near Colombia on the coast (n).
439. *Thelypteris* (*Amauropelta*) sp., aff. *gracilis* (Heward) Proctor; YU. 29/1/57 [1/1]; 3,500 ft.; seaside of mountain range between Maracai and Choroni (n).
440. *Thelypteris* (*Amauropelta*) *pilosula* (Mett.) R. Tryon; YU. 6/1/57 [1/1]; 8,000 ft.; highest mountains E of Colonia Tovar (n).
441. *Thelypteris* (*Cyclosorus*) *hispidula* (Decne.) Reed; YU. [2/1]; 4,000 ft.; a few mi. SW of Colonia Tovar (n).
442. Not located. 25/1/57 [1/?]; 300 ft.; seaside of mountains between Maracai and Choroni (n).
443. *Cyclopeltis semicordata* (Sw.) J. Smith; MO. 25/1/57 [1/?]; 200 ft.; between Choroni and Colombia (n).
444. "*Ctenitis microchlaena*" (Fée) A. R. Smith, comb. ined.; YU. 9/2/57 [1/1]; 5,000 ft.; seaside of mountains between Petaquire and the sea (n).
445. *Thelypteris* (*Goniopteris*) *nephrodioides* (Klotzsch) Proctor; YU. 9/2/57 [1/1]; 3,000 ft.; seaside of mountains between Petaquire and the sea (n).
446. *Thelypteris* (*Goniopteris*) *paucijuga* (Klotzsch) A. R. Smith, vel aff.; YU. 9/2/57 [1/3]; 4,000 ft.;

seaside of mountains between Petaquire and the sea (n).

447. *Ctenitis pulverulenta* (Poiret) Copel.; K, YU—2; cited by Christensen (1920) as *Dryopteris karsteniana* (Klotzsch) Hieron. 9/2/57 [1/3]; 3,000 ft.; seaside of mountains between Petaquire and the sea (n).
448. *Dennstaedtia bipinnata* (Cav.) Maxon; MO, YU—2. [3/5]; 4,000 ft.; seaside of mountains north of Colonia Tovar (n).
449. = 450*β* (n).
450. *Dicranopteris seminuda* (Klotzsch) Maxon; MO, YU—2. [3/20]; 6,500 ft.; high mountains NE of Colonia [Tovar] (n).
450*β*. *Dicranopteris flexuosa* (Schrader) L. Underw.; MO, YU. 9/2/57 [1/6] (s).
451. *Trichomanes* (*Acarpacrium*) *trigonum* Desv.; YU. 28/1/57 [1/1]; 4,500 ft.; seaside of mountain range between Maracai and Choroni (n).
452. *Trichomanes* (*Didymoglossum*) *punctatum* Poiret subsp. *sphenoides* (Kunze) W. Boer; B, G, GH, MO, YU; cited by Wessels Boer (1962). 29/1/57 [1/19]; 4,500 ft.; seaside of mountains between Maracai and Choroni (n).
453. *Trichomanes* (*Lecanium*) *membranaceum* L.; MO, YU. 10/2/57 [1/20]; 3,000 ft.; seaside of mountain range between Petaquire and the sea (n).
454. *Trichomanes* (*Didymoglossum*) *lineolatum* (Bosch) Hook.; B, G, GH, MO, YU; cited by Wessels Boer (1962). 10/2/57 [1/16]; 3,500 ft.; seaside of mountain range between Petaquire and the sea (n).
455. *Trichomanes* (*Microgonium*) *ekmanii* W. Boer; B, G, GH, L, MO, US; cited by Wessels Boer (1962). 13/12/56 [1/?]; 5,500 ft.; seaside of mountains between Maracai and Choroni (n).
456. *Trichomanes* (*Lacosteopsis*) *rupestre* (Raddi) Bosch; YU. 29/1/57 [1/2]; 3,000 ft.; seaside of mountains between Maracai and Choroni (n).
457. *Hymenophyllum* (*Sphaerocionium*) *elegans* Sprengel forma *minor* C. Morton; GH, MO, YU; cited by Morton (1947). 29/1/57 [1/19]; 6,200 ft.; seaside of mountains between Maracai and Choroni (n).
458. *Hymenophyllum* (*Sphaerocionium*) *hirsutum* (L.) Sw. 29/1/57 [1/?]; 6,000 ft.; seaside of mountain ridge between Maracai and Choroni (n).
459. *Trichomanes* (*Lacosteopsis*) *debile* Bosch; MO, YU—2. 10/3/57 [1/14]; 5,000 ft.; seaside of mountains between Valencia and San Estevan (n).
460. *Danaea elliptica* J. E. Smith; MO, YU. 3,500 ft.; seaside of mountain range between Petaquire and Chichiribichi (n); 9/2/57 [1/10] (s).
461. *Selaginella haematodes* (Kunze) Spring in Martius; MO, YU. 9/2/57 [1/16]; 2,500 ft.; seaside of mountain range between Petaquire and Chichiribichi (n).
462. = *313*, not located.
463. *Elaphoglossum ornatum* (Mett.) Christ; K, YU; cited by Mickel in Smith (1985). [2/4]; 3,000 ft.; seaside of mountain range between Agua Blanca and Cumbote (n).
464. *Pleopeltis percussa* (Cav.) Hook. & Grev.; YU. [?/1]; 6,500 ft.; Colonia Tovar (n). On same sheet as *421*.
465. *Grammitis* sp.; YU; cited by Eaton (1861) as *Polypodium truncicola* Klotzsch. [2/?]; 6,000 ft.; seaside of mountains between Valencia and San Estevan and between Agua Blanca and Cumbote (n).
466. *Elaphoglossum* sp.; YU; cited by Eaton (1861) as *Acrostichum perelegans* Fée. 7/3/57 [1/?]; 4,000 ft.; seaside of mountain range between Valencia and Campanero (n).
467. *Grammitis chrysleri* (Copel.) Proctor; YU. 30/1/58 [1/3]; 6,500 ft.; seaside of mountains between Agua Blanca and Cumbote (n).
468. *Adiantum latifolium* Lam.; YU. 7/3/57 [1/2]; 1,000 ft.; between Valencia and San Estevan, seaside of mountain range (n).
469. *Adiantum petiolatum* Desv.; YU. [2/4]; 500–1,000 ft.; near San Estevan a few mi. N of Puerto Cabello (n).
469*β*. *Adiantum* sp.; YU; cited by Eaton (1861) as *A. kaulfussii* Kunze [may be *A. petiolatum* Desv.].
470. = *469β* (n), not located.
471. *Polypodium triseriale* Sw.; YU. 7/5/57 [1/1]; 7,000 ft.; high mountains E of Colonia [Tovar] (n).
472. *Thelypteris* (*Amauropelta*) *pachyrhachis* (Kunze ex Mett.) Ching var. *pachyrhachis*; GH, MO, YU. [2/6]; 4,000 ft.; seaside of mountains between Agua Blanca and Cumbote, and between Valencia and San Estevan (n).
473. *Thelypteris* (*Cyclosorus*) *conspersa* (Schrader) A. R. Smith; YU. [2/3]; 4,000 ft.; Macarao River valley W of Caracas, also seaside of mountains between Valencia and San Estevan (n).
473. *Thelypteris* (*Cyclosorus*) *hispidula*; YU. [?/3].
474. *Thelypteris* (*Goniopteris*) *straminea* (Baker) Reed; YU; this is an ISOTYPE of *Polypodium stramineum* Baker in Hook. & Baker, Syn. Fil. 316. 1867. [1/4]; 2,300 ft.; Piedernales near Güigüe (n).
475. *Thelypteris* (*Cyclosorus*) *hispidula* (Decne.) Reed; YU. 7/3/57 [1/1]; 2,500 ft.; seaside of mountains between Valencia and San Estevan (n).
476. *Thelypteris* (*Steiropteris*) *leprieurii* (Hook.) R. Tryon var. *costalis* (Baker) A. R. Smith; K; this is an ISOTYPE of *Aspidium costale* Mett. ex Kuhn, Linnaea 36: 111. 1869. 7/3/57 [1/?]; 1,500 ft.; seaside of mountains between Valencia and San Estevan (n).
477. *Thelypteris* (*Steiropteris*) *leprieurii* (Hook.) R. Tryon var. *costalis* (Baker) A. R. Smith; YU. 7/3/57 [1/1]; 1,500 ft.; seaside of mountain range between Valencia and San Estevan (n).
478. Not located. 7/3/57 [1/?]; 1,000 ft.; seaside of mountain range between Valencia and San Estevan (n).
479. *Lindsaea stricta* (Sw.) Dryander var. *stricta*; G, GH, GOET, K, MO, PH, YU; cited by Kramer (1957). 7/3/57 [1/12]; 4,000 ft.; seaside of mountain range between Valencia and San Estevan (n).
480. *Cnemidaria spectabilis* (Kunze) R. Tryon var. *spectabilis*; GH, K, MO, YU—2; cited by Stolze (1974). 7/3/57 [1/9]; 4,500 ft.; seaside of mountain range between Valencia and San Estevan (n).
481. *Hymenophyllum* (*Sphaerocionium*) *dependens* C. Morton; GH, US, MO, YU; cited by Morton (1947). 29/1/58 [1/?]; 5,000 ft.; seaside of mountain range between Agua Blanca and Cumbote (n).
482. *Dicranopteris pectinata* (Willd.) L. Underw.; MO, YU. 7/3/57 [1/6]; 6,000 ft.; seaside of mountains between Valencia and San Estevan (n).
483. *Dicranopteris pectinata* (Willd.) L. Underw.; MO, YU. 7/3/57 [1/5]; 5,500 ft.; seaside of mountains between Valencia and San Estevan (n).

484. Not located. 7/3/57 [1/?]; 5,500 ft.; seaside of mountains between Valencia and San Estevan (n).
485. *Schizaea poeppigiana* Sturm in Martius; MO. 27/2/57 [1/?]; 5,800 ft.; a few mi. S of Colonia Tovar (n).
486. = *322*, *Selaginella* (n), not located. 7/3/57 [1/?]; 4,000 ft.; seaside of mountains between Valencia and San Estevan (n).
487. *Selaginella cruciformis* Alston ex Crabbe & Jermy; BM; cited by Alston et al. (1981). 7/3/57 [1/?]; 3,000 ft.; seaside of mountains between Valencia and San Estevan (n).
487?. *Lophosoria quadripinnata* (J. Gmelin) C. Chr.; YU. [?/7].
488. *Polypodium fraxinifolium* Jacq.; YU. 26/3/57 [1/1]; 8,000 ft.; high mountains E of Colonia Tovar (n).
489. *Asplenium serratum* L.; YU. 7/3/57 [1/3]; 3,500 ft.; seaside of mountain range between Valencia and San Estevan (n).
490. Not located. 7/3/57 [1/?]; 4,000 ft.; seaside of mountain range between Valencia and San Estevan (n).
491. *Cyathea barringtonii* A. R. Smith ex Lellinger; YU; cited by Barrington (1978) as *Trichipteris cordata* (Klotzsch) R. Tryon. [2/2]; 6,300 ft.; seaside of mountain range between Maracai and Choroni (n).
492. *Cyathea villosa* Willd.; YU. [2/4]; 5,800 ft.; seaside of mountain range between Agua Blanca and Cumbote, also savannahs S of Colonia [Tovar] (n).
492?. *Cyathea villosa* Willd.; YU.
493. *Selaginella flabellata* (L.) Spring var. *latifrons* A. Braun, Ann. Sci. Nat. Bot., V. 3: 278. 1865; ISOTYPES, BM, MO, YU; cited by Alston et al. (1981). 30/1/58 [1/4]; 3,000 ft.; seaside of mountains between Agua Blanca and Cumbote (n).
494. *Selaginella cavifolia* A. Braun; YU. [2/4]; 6,000 ft.; Colonia Tovar (n).
495. *Elaphoglossum variolatum* Mickel; YU. 4,000 ft.; seaside of mountain range between Agua Blanca and Cumbote (n); 30/1/58 [1/1] (s).
496. *Adiantum* sp.; YU; cited by Eaton (1861) as *A. capillus-veneris* L. 20/2/58 [1/?]; 3,000 ft.; Hacienda Curisal (n).
497. *Diplazium celtidifolium* Kunze; YU. 22/4/58 [1/1]; 4,500 ft.; seaside of mountain range between Petaquire and the sea (n).
498. *Diplazium flavescens* (Mett.) Christ; MO, YU. 22/4/58 [1/?]; 4,000 ft.; seaside of mountain range between Petaquire and the sea (n).
499. *Rumohra adiantiformis* (G. Forster) Ching; YU; cited by Eaton (1861) as *Aspidium coriaceum* Sw. 22/4/58 [1/?]; 5,500 ft.; seaside of mountains between Petaquire and the sea (n).
s.n. *Lindsaea klotzschiana* Moritz in Ettingshausen; YU; originally det. *L. quadrangularis* Raddi.

INDEX

Below is an alphabetical list of pteridophyte species collected in Venezuela by Fendler. The numbers refer to the Fendler collection numbers in the list of determinations.

Adiantopsis radiata (L.) Fée—67
Adiantum braunii Mett. ex Kuhn—68
A. capillus-veneris L.—72, pt
A. concinnum Humb. & Bonpl. ex Willd.—73, pt; ad 73; 73/76; 75; ad 75; 75β; 76; 77
A. deflectens Martius—81
A. fructuosum Sprengel—83, pt
A. henslovianum Hook.—72, pt; 78
A. latifolium Lam.—468
A. lunulatum Burm. f.—73, pt; 82
A. macrophyllum Sw.—88
A. patens Willd.—79
A. petiolatum Desv.—87; 469
A. poiretii Wikstr.—71
A. polyphyllum Willd.—80
A. pulverulentum L.—83, pt; 86
A. raddianum C. Presl—74
A. serratodentatum Willd.—84
A. tenerum Sw.—69; 70
A. tetraphyllum Humb. & Bonpl. ex Willd.—ad 85; 364, pt
A. villosum L.—85
A. sp.—469β; 496
Anemia ferruginea H.B.K. var. *ferruginea*—7
A. hirsuta (L.) Sw.—8; 15
A. oblongifolia (Cav.) Sw.—9; 9β; 10
A. pastinacaria Moritz ex Prantl—11
A. phyllitidis (L.) Sw.—13
A. villosa Humb. & Bonpl. ex Willd.—6
A. sp., undescribed?—12; 12β
Anetium citrifolium (L.) Splitg.—425
Antrophyum brasilianum (Desv.) C. Chr.—305, pt
A. cajenense (Desv.) Sprengel—305, pt
A. lineatum (Sw.) Kaulf.—304
Arachniodes denticulata (Sw.) Ching—117, pt; 170
Asplenium abscissum Willd.—143, pt; 143β
A. alatum Humb. & Bonpl. ex Willd.—145
A. auriculatum Sw.—331β; 432
A. auriculatum Sw., vel aff.—144
A. auritum Sw. var. *obtusum* Kunze ex Mett.—141
A. cirrhatum Rich. ex Willd.—140, pt; 367; 434
A. claussenii Hieron.—138; 139γ
A. cristatum Lam.—124; ad 124; 134, pt
A. aff. *cristatum* Lam.—124β
A. flabellulatum Kunze—125, pt
A. flabellulatum Kunze var. *partitum* Klotzsch—125, pt; 127β
A. formosum Willd.—133
A. harpeodes Kunze—135
A. laetum Sw., vel aff.—136
A. lividum Mett. ex Kuhn—156
A. melanopus Sodiro—143γ
A. monanthes L.—134, pt
A. monodon Liebm.—142β
A. monodon Liebm.?—142; ad 142
A. obtusifolium L.—131
A. oligophyllum Kaulf.—143, pt; 326
A. praemorsum Sw.—157; 157β
A. pteropus Kaulf.—433
A. pumilum Sw.—130
A. raddianum Gaud.—137
A. radicans L.—126; 126β; 127; 140, pt
A. ruizianum Klotzsch—139; 139β
A. rutaceum (Willd.) Mett.—123
A. salicifolium L.—331
A. serra Langsd. & Fischer—155; 332; 333
A. serratum L.—489
A. squamosum L.—132
A. tenerrimum Mett. ex Kuhn—368

A. sp.—411
Athyrium filix-femina (L.) Roth—405
A. skinneri (Baker) C. Chr.—163
Blechnum ×*caudatum* Cav.—112; 113
B. cordatum (Desv.) Hieron.—118; 119
B. aff. *cordatum* (Desv.) Hieron.—121
B. divergens (Kunze) Mett.—309
B. fragile (Liebm.) C. Morton & Lellinger, vel aff.—308
B. fraxineum Willd.—114
B. lehmannii Hieron.—310
B. occidentale L.—106; 107; 108
B. polypodioides Raddi—110
B. schomburgkii (Klotzsch) C. Chr.?—340
B. sp.—110β; 111; 115; 116; 120; 122
Blechnum hybrid?—109
Bolbitis hemiotis (Maxon) Ching—408
B. portoricensis (Sprengel) Hennipman—336
B. serratifolia (Mertens ex Kaulf.) Schott—311
Botrychium sp.—4
Campyloneurum amphostenon (Kunze ex Klotzsch) Fée—226; ad 226
C. angustifolium (Sw.) Fée—224, pt
C. chlorolepis Alston—224, pt; 225
C. chrysopodum (Klotzsch) Fée—228; 228β
C. decurrens (Raddi) C. Presl—231
C. magnificum T. Moore—410
C. occultum (Christ) L. D. Gómez—409
C. phyllitidis (L.) C. Presl—227
C. repens (Aubl.) C. Presl—229; 230
Cheilanthes concolor (Langsd. & Fischer) R. & A. Tryon—92
C. marginata H.B.K.—90
C. microphylla (Sw.) Sw.—65
C. sp.—404
Cnemidaria horrida (L.) C. Presl—385
C. karsteniana (Klotzsch) R. Tryon—386
C. spectabilis (Kunze) R. Tryon var. *spectabilis*—480
Cochlidium rostratum (Hook.) Maxon ex C. Chr.—355
C. serrulatum (Sw.) L. E. Bishop—356
Ctenitis ampla Humb. & Bonpl. ex Willd.) Ching—204
"*C. microchlaena*" (Fée) A. R. Smith, comb. ined.—444
C. nigrovenia (Christ) Copel.—194
C. pulverulenta (Poiret) Copel.—447
C. sloanei (Sprengel) C. Morton—203
C. subincisa (Willd.) Ching—202
C. submarginalis (Langsd. & Fischer) Ching—195; 197
Cyathea barringtonii A. R. Smith ex Lellinger—491
C. caracasana (Klotzsch) Domin var. *caracasana*—56; ad 56
C. ebenina Karsten—50
C. fulva (Mart. & Gal.) Fée—51; 52
C. gibbosa (Klotzsch) Domin—54; 382
C. pungens (Willd.) Domin—55
C. senilis (Klotzsch) Domin—383
C. speciosa Willd.—46; 46β
C. squamata (Klotzsch) Domin—53
C. tryonorum (Riba) Lellinger—49; 49β
C. villosa Willd.—47; 344; 492; 492?
Cyclopeltis semicordata (Sw.) J. Smith—443
Danaea elliptica J. E. Smith—460
D. moritziana C. Presl—1
Dennstaedtia arborescens (Willd.) Ekman ex Maxon—60
D. bipinnata (Cav.) Maxon—448
D. cicutaria (Sw.) T. Moore—58
D. dissecta (Sw.) T. Moore—59
D. obtusifolia (Willd.) T. Moore—374
Dicksonia sellowiana Hook.—57
Dicranoglossum furcatum (L.) J. Smith—423
Dicranopteris flexuosa (Schrader) L. Underw.—44; 449; 450β
D. pectinata (Willd.) L. Underw.—482; 483
D. seminuda (Klotzsch) Maxon—450
Didymochlaena truncatula (Sw.) J. Smith—160
Diplazium caracasanum (Willd.) Kunze ex T. Moore—129; 129β
D. celtidifolium Kunze—153; 497
D. centripetale (Baker) Maxon, vel aff.—152
D. cristatum (Desr.) Alston—128; 128β
D. diplazioides (Klotzsch & Karsten ex Klotzsch) Alston—146; 149
D. expansum Willd.—369
D. flavescens (Mett.) Christ—498
D. hians Kunze ex Klotzsch—147; 148
D. macrophyllum Desv.—334
D. mutilum Kunze—151
D. pedatum Klotzsch—435; 435β; 436
D. plantaginifolium (L.) Urban—154
D. aff. *striatum* (L.) C. Presl—150
Diplopterygium bancroftii (Hook.) A. R. Smith—45
Doryopteris pedata (L.) Fée var. *palmata* (Willd.) Hicken—91
D. sagittifolia (Raddi) J. Smith—366
Dryopteris patula (Sw.) L. Underw.—168; 169
Elaphoglossum affine (Mart. & Gal.) T. Moore—275α
E. ambiguum (Mett. ex Christ) Alston—283; 284
E. andicola (Fée) T. Moore—293, pt
E. bellermannianum (Klotzsch) T. Moore—270
E. brachyneuron (Fée) J. Smith—282
E. burchellii (Baker) C. Chr.—280
E. chrysopogon Mickel—278; 279
E. crinitum (L.) Christ—363
E. cuspidatum (Willd.) T. Moore—271
E. deorsum (Karsten) Vareschi—269β
E. erinaceum (Fée) T. Moore—264
E. eximium (Mett.) Christ—265; 281
E. glabellum J. Smith—391
E. herminieri (Bory & Fée ex Fée) T. Moore—428
E. hieracioides Mickel—268
E. hoffmannii (Mett. ex Kuhn) Christ—290
E. huacssaro (Ruiz) Christ—276
E. lingua (C. Presl) Brackenr.—285; 429
E. lloense (Hook.) T. Moore—286
E. macrophyllum (Klotzsch) Christ—287
E. meridense (Klotzsch) T. Moore—269
E. moritzianum (Klotzsch) T. Moore—266
E. ornatum (Mett.) Christ—463
E. peltatum (Sw.) Urban forma *flabellatum* (Humb. & Bonpl. ex Willd.) Mickel—263
E. peltatum (Sw.) Urban var. *peltatum*—361
E. piloselloides (C. Presl) T. Moore—267
E. pusillum (Mett. ex Kuhn) C. Chr.—362; 364, pt

NOTES

A NEW *ECHEANDIA* (LILIACEAE) FROM VENEZUELAN GUAYANA

Echeandia bolivarensis Cruden, sp. nov. TYPE: Venezuela. Bolívar: Igneous forested slopes, Serranía de Pijiguao, 160 km SW of Caicara del Orinoco, 6°35′N, 66°45′W, 100–125 m, 12 Sep. 1985, *Steyermark, Holst & Manara* 131761 (holotype, MO, on two sheets, 3472626, 3472627; isotype, UC).

Regio penaria radicum ab cormo 4–5 cm, 4–5 cm longa. Folia basalia 6–10, anguste oblanceolata, marginibus denticulatis-serrulatis, 45–60 cm longa, 11–18 mm lata. Scapus glaber, 4–5 ramosus. Folia caulina 4–5, longiattenuata. Tepala flava. Filamenta squamata, linearia. Antherae librae. Capsula late oblonga.

Storage region of the roots 4–5 cm from the corm, 4–5 cm long. Basal leaves 6–10, ascending, narrowly lanceolate above the base, bases persistent as a fibrous collar, minutely denticulate-serrulate, usually 45–60 cm long and 11–18 mm wide. Scape glabrous, 98–118 cm high, 5-branched. Cauline leaves 4–5, long-attenuate. Tepals yellow, ca. 10 mm long. Filaments minutely to noticeably scaled, linear, 6.5 mm long. Anthers free, 2.4–3 mm long, appearing to dehisce laterally. Ovary 2 mm long. capsule broadly oblong, 10–11 mm long, 6.5–7.5 mm wide. Seeds black, colliculose, 2.5–3 mm across.

Known only from the type locality, this species is easily distinguished from other yellow-flowered South American *Echeandia* species by the combination of scaled filaments, many branches, and the storage organs developing at some distance from the corm. It is unusual for yellow-flowered species to occur at such low elevations.

—Robert William Cruden, *Department of Botany, University of Iowa, Iowa City, Iowa 52242, U.S.A.*

Ann. Missouri Bot. Gard. 76: 350. 1989.

SOLANUM TOLIARAEA, A NEW SPECIES FROM MADAGASCAR

Solanum toliaraea D'Arcy & Rakotozafy, sp. nov. TYPE: Madagascar: *D'Arcy & Rakotozafy 15460* (holotype, MO; isotypes, K, P, TAN).

Frutex armatus spinis brevibus validis rectis, foliis rotundis parvis stellato-tomentosis; flores solitari v-geminati, calyce inermi sed in statu fructu accrescenti, echiniformi, acinum tegenti.

Slender, branched shrub or tree to 3 m tall; twigs slender, at first appressed tomentose with reddish hairs, soon puberulent with reduced buff-colored trichomes and deeply furrowed, armed with short, stout-based, nearly straight, puberulent spines. Leaves mostly paired in fasciculate short-shoots, entire, rotund, apically rounded, basally rounded, truncate or cordate, mostly 8–20 mm long, thick, felty with dense short-stalked, stellate hairs, the costa evident, the minor venation obscure; peduncles canaliculate adaxially but often appearing terete because of the dense tomentum, mostly 5–10 mm long, with occasional small straight spines. Inflorescences solitary flowers or paired fascicles from the leafy short-shoots; pedicels resembling the petioles but somewhat longer. Flowers with calyx ca. 4 mm long, lobed about ⅓ way down, the lobes convex, obtuse, tomentose, unarmed; corolla pale purple, mauve, or white, ca. 10 mm long, lobed ⅓ way down, tomentose outside except on the membranaceous inter-lobe fringing areas, glabrous within, the nervature drying conspicuous within; stamens 5, equal, the anthers yellow, slender, 5 mm long, opening by minute terminal pores; ovary glabrous, drying somewhat lobed, the style slender, exserted slightly beyond the stamens, with a few short, gland-tipped simple hairs near the base. Berry green, juicy, 4-lobed, ca. 5 mm diam., entirely but loosely enveloped in the calyx, the spiny, accrescent calyx echinoid, subglobose, ca. 2 cm diam.; seeds (*Descoings 2375*) compressed, dark, 2.5 mm long.

At time of flowering the calyx of this species is devoid of spines, in contrast to its copiously spiny, echinoid condition when in fruit.

Collections of this species were first confused with *Solanum dubium* Fresen of Ethiopia, which has similar spiny accrescent calyces, but that species is herbaceous and has much larger, lobed leaves. The species described here differs from the other two arborescent species of southwestern Madagascar in its accrescent, spiny calyx and in its rotund, concolorous leaves. *Solanum toliaraea* is sympatric, at least in part, with other arborescent solanums, *S. bummeliifolium* Dunal and *S. heineanum* D'Arcy & Keating, which differ in usually spineless calyces and porrect, scutellate hairs.

Solanum toliaraea was seen as scattered individuals in didieriad woodlands of southwestern Madagascar. Most collections were made from plants growing on sand near the coast just north of the major city of Tulear and hence just north of the Tropic of Capricorn.

The name *toliaraea* is derived from the Malagasy spelling for the city of Tulear.

Material seen. MADAGASCAR: TULEAR (Toliary): bush à *Didierea* sur dunes, embouchure de Fiherenana, Belalanda, Nov. 1956, *Bosser 10472* (MO, P); scrub forest on pure shifting sand, 8 km N of Tulear on road to Morombe, 5 Feb. 1975, *Croat 30778* (MO); road to 5 km N of Belalanda, 17 May 1983, *D'Arcy & Rakotozafy 15460* (MO, K, P, TAN); Sable, Manombo, région de Tuléar, *Decary 16214, 18714* (P); route de Manombo sur sable, 7 Jan. 1957, *Descoings 2375* (MO); bush à *Didierea* sur dunes, embouchure de Fiherenana, Belalanda, May 1960, *Keraudren 690* (P); bush à Euphorbiés, route de Monombo, près de la côte, environs de Tuléar, 3 Nov. 1960, *Léandri & Jean de Dieu 3627, 3635, 3804* (P); thorn scrub of *Euphorbia* and *Didierea* on

NOTE CONCERNING *FESTUCA HENRIQUESII* (GRAMINEAE) IN NORTHERN PORTUGAL

The species *Festuca henriquesii* Hackel (Gramineae), first described in 1883, is endemic to Portugal. In various floras and subsequent publications, namely Coutinho (1939), Sampaio (1946), Litardière (1952), and Tutin et al. (1980), the location of this species has been given as restricted solely to the Serra da Estrela, a mountain range in northeastern Portugal. Little information is available concerning its ecology, except that specimens have generally been collected from high places in this mountain range.

Recently, however, I recorded this species from a grassland area in the Serra do Gerês, in northern Portugal (Hale, in press). I had believed that this was the first record for the species outside of the Serra da Estrela range. The location, in grazed grassland within an area generally of ericaceous shrubland, is known as "Lagoas" because of two small nearby lakes. The plants were growing on an acid soil over granitic parent material at an altitude of 1,150 m (grid reference X326 071; Carta Militar 31).

Further investigation revealed, however, that this record for the species in the Serra do Gerês was not unique. Besides two records from the Serra da Estrela, three specimens of *F. henriquesii* exist in the Herbarium of the Institute of Botany "Dr. Gonçalo Sampaio" in Porto, collected from the Serra do Gerês and nearby areas (Table 1). Despite the existence of these specimens, however, this species appears not to have been previously reported from these mountain ranges.

It is clear from these records that *Festuca henriquesii* is not restricted to the Serra da Estrela; the range includes the serras of Gerês, Peneda, and Barroso. The species might be a glacial relict restricted to a few mountain ranges and not noticed before outside of the Serra da Estrela; alternatively, its distribution may be expanding. In view of the apparently discontinuous distribution, these other mountain ranges being nearly 200 km from that of Estrela, it is quite possible that the species might turn up in other intervening mountain ranges in the north of Portugal.

TABLE 1. *F. henriquesii* records outside Estrela.

Location	Habitat	Date of Collection
Lamas do Homem, Gerês	Dry ground	6/7/1948
Barca do Homem, Gavieira, Peneda	Grassland	–/7/1961
S. Fins, Montalegre, Barroso	Roadside	11/8/1978
Lagoas, Gerês	Grassland	6/7/1984

I thank the staff of the Herbarium of the Institute of Botany "Dr. Gonçalo Sampaio," Porto, for confirming the identification of the "Lagoas" specimen and for access to the previous records of the species.

PASSIFLORA CITRINA, A NEW SPECIES IN SECTION *XEROGONA* (PASSIFLORACEAE), FROM MESOAMERICA

The center of diversity for *Passiflora* L. subg. *Plectostemma* Masters sect. *Xerogona* (Raf.) Killip is in northern Central America, where at least six species occur in Guatemala alone. The section is notable in the genus *Passiflora* for its unusual capsular fruit. Killip (1922, 1924, 1927) described five species of this section from Central America and southern Mexico that had been confused with *P. rubra* L. or *P. capsularis* L. Newly described here is the yellow-flowered *P. citrina*, yet another member of this section that has been hidden under misapplication of the name *P. capsularis*.

Passiflora citrina MacDougal, sp. nov. TYPE: Honduras. Comayagua: El Carrizal, 14 km NW of Siguatepec, 900 m, 27 June 1971, *Molina & Molina 26057* (holotype, F; isotypes, EAP, NY, US). Figure 1.

Passiflora pubescens scandens; caulis sub5-angulatus; petioli eglandulosi; folia bilobata vel trilobata, lobis lateralibus acuminatis vel rotundis, lobo centrali obtuso vel obsoleto, marginibus integris, angula inter lobos laterales (30–)35–55(–70)°; bracteae nullae vel raro floribus bractea solitaria, 2–4 mm longa praeditis; flores aurei vel citrini vel viridiflavi, prope bases subcylindrico; coronae filamenta uniseriata, connata per maiorem longitudinem et perianthio adnata; androgynophorum 21–28 mm longum; ovarium dense pubescens; fructus fusiformis vel obovoideus, conspicue 6-carinatus; semina 6–7(8) sulcata.

Small vine, pubescent to hirsutellous throughout with 0.10–1.0(–1.2) mm ± erect, slightly antrorsely inclined or bent trichomes. Stems subpentangular, striate, densely pubescent with 0.2–0.8-mm bent trichomes. Stipules 4–7(–11) × 0.5–0.9 mm, linear-triangular, falcate, the apices not necrescent. Petioles 0.3–1.2(–2.0) cm long, eglandular. Laminas (2–)3–6.5(–9) × (1.5–)3–7(–9.5) cm at fertile nodes, widely obovate (obtriangular to widely oblong) in general outline, rounded to truncate (very shallowly cordate) at the base, entire, adaxially sometimes variegated along the main veins of the lateral lobes, evenly pubescent or often the trichomes in 2 distinct size classes and then the leaf scabrous and lightly hirsutellous, abaxially densely pubescent, 2(–3)-lobed 0.07–0.4(–0.6) the distance to the base, the lateral lobes acuminate to rounded, the central lobe (acute) obtuse to obsolete, the angle between the lateral lobes (30–)35–55(–70)°, the ratio of lateral to central lobe lengths (1.0–)1.2–2.0(–2.5), the ratio of laminar width to length (0.50–)0.6–0.9(–1.1); juvenile leaves variegated, deeply 2-lobed, the lobes acuminate, the angle between the lobes 80–100° or more; laminar nectaries absent. Posture of shoot apex ± straight. Prophyll of vegetative ramifying bud 1, narrowly lanceolate-triangular. Peduncles (solitary) geminate at the nodes, (0.3–)0.7–3.2(–4.3) cm long, uniflorous, ebracteate or rarely with one bract near the apex, 2–4 × 0.2–0.4 mm, linear to linear-triangular. Flowers yellow or bright yellow (to greenish yellow), sometimes drying with reddish brown speckles, inodorous, cylindrical in bud, the ventricose hypanthium 5–9 mm diam., sometimes with some of the trichomes borne on slightly raised bases; floral stipe 1.5–4 mm long; sepals 20–28(–34) × 2.5–5 mm, narrowly oblong-lanceolate or slightly oblanceolate, basally connate 2–6 mm, ecorniculate, strongly 3-veined, the veins raised and hirsutellous; petals 19–28 × 1.7–2.6 mm, narrowly oblong-lanceolate, basally adnate to the sepals; coronal filaments in 1 series, 9–14 mm long, erect, variably connate much of their length and adnate to the perianth, free distally 3–6 mm, pale yellow with yellow tips, not banded; operculum 1.0–2.1 mm long, membranous, only barely plicate near the erose apex; nectary 5(10)–ventricose, an additional annulus absent; limen (disk) ca. 2 mm diam., closely surrounding the base of androgynophore; staminal filaments connate 21–28 mm along the androgynophore, the free portions 4.5–6.0 mm long; anthers 4.4–6.0 mm long; ovary 2.8–4.2(–5.0) × 1.5–2.3 mm, obovoid-ellipsoid, densely pubescent, the trichomes mostly 0.2–0.5 mm; styles 5.0–6.8 mm total length; stigmas ca. 1.3 mm diam. Fruit (2.5–)3–4.3 × 1.2–2.3 cm, fusiform-ellipsoid or slightly obovoid, basally conical

or slightly attenuate, apically conical, acutely 6-carinate with thin 1–2-mm-high ridges, pubescent, reddish, dehiscent?, the stipe 1–8 mm long; arils unknown; nearly mature seeds 3.5–4 × 2.2–2.4 mm, slightly obcampylotropous with the chalazal beak strongly inclined toward the raphe, transversely sulcate with 6–7(–8) sulcae, the ridges continuous, smooth, and rather flat.

Habitat and distribution. *Passiflora citrina* is endemic to the pinehills country of central to western Honduras and adjacent eastern Guatemala. There it has been collected in moist (often open) pinewoods, *Pinus–Liquidambar* forest, or edges of moist mixed forest; it usually is climbing over grasses, tall herbs, and small shrubs in thickets.

Vernacular names. The name "moco" is recorded on an herbarium sheet from Chiquimula, Guatemala. "Calzoncillo," a vernacular name used for several of the bilobed passifloras in Mesoamerica, is recorded from Intibucá, Honduras.

Misapplied names. *Passiflora capsularis* auct., non L.: Killip (1936, 1938), in part; Standley & Williams (1961), in part.

The specific epithet refers to the color of the flowers.

Additional specimens examined. GUATEMALA. CHIQUIMULA: La Cumbre, old road to Quezaltepeque, 1,500 m, 28 Sep. 1971 (fl), *Molina & Molina 26821* (F); Volcán Quezaltepeque, 3–4 mi. Téllez 12932* (DUKE, MEXU); El Moral on Cordillera Merendón, 1,600 m, 27 Aug. 1968 (fl), *Molina 22263* (F, NY).

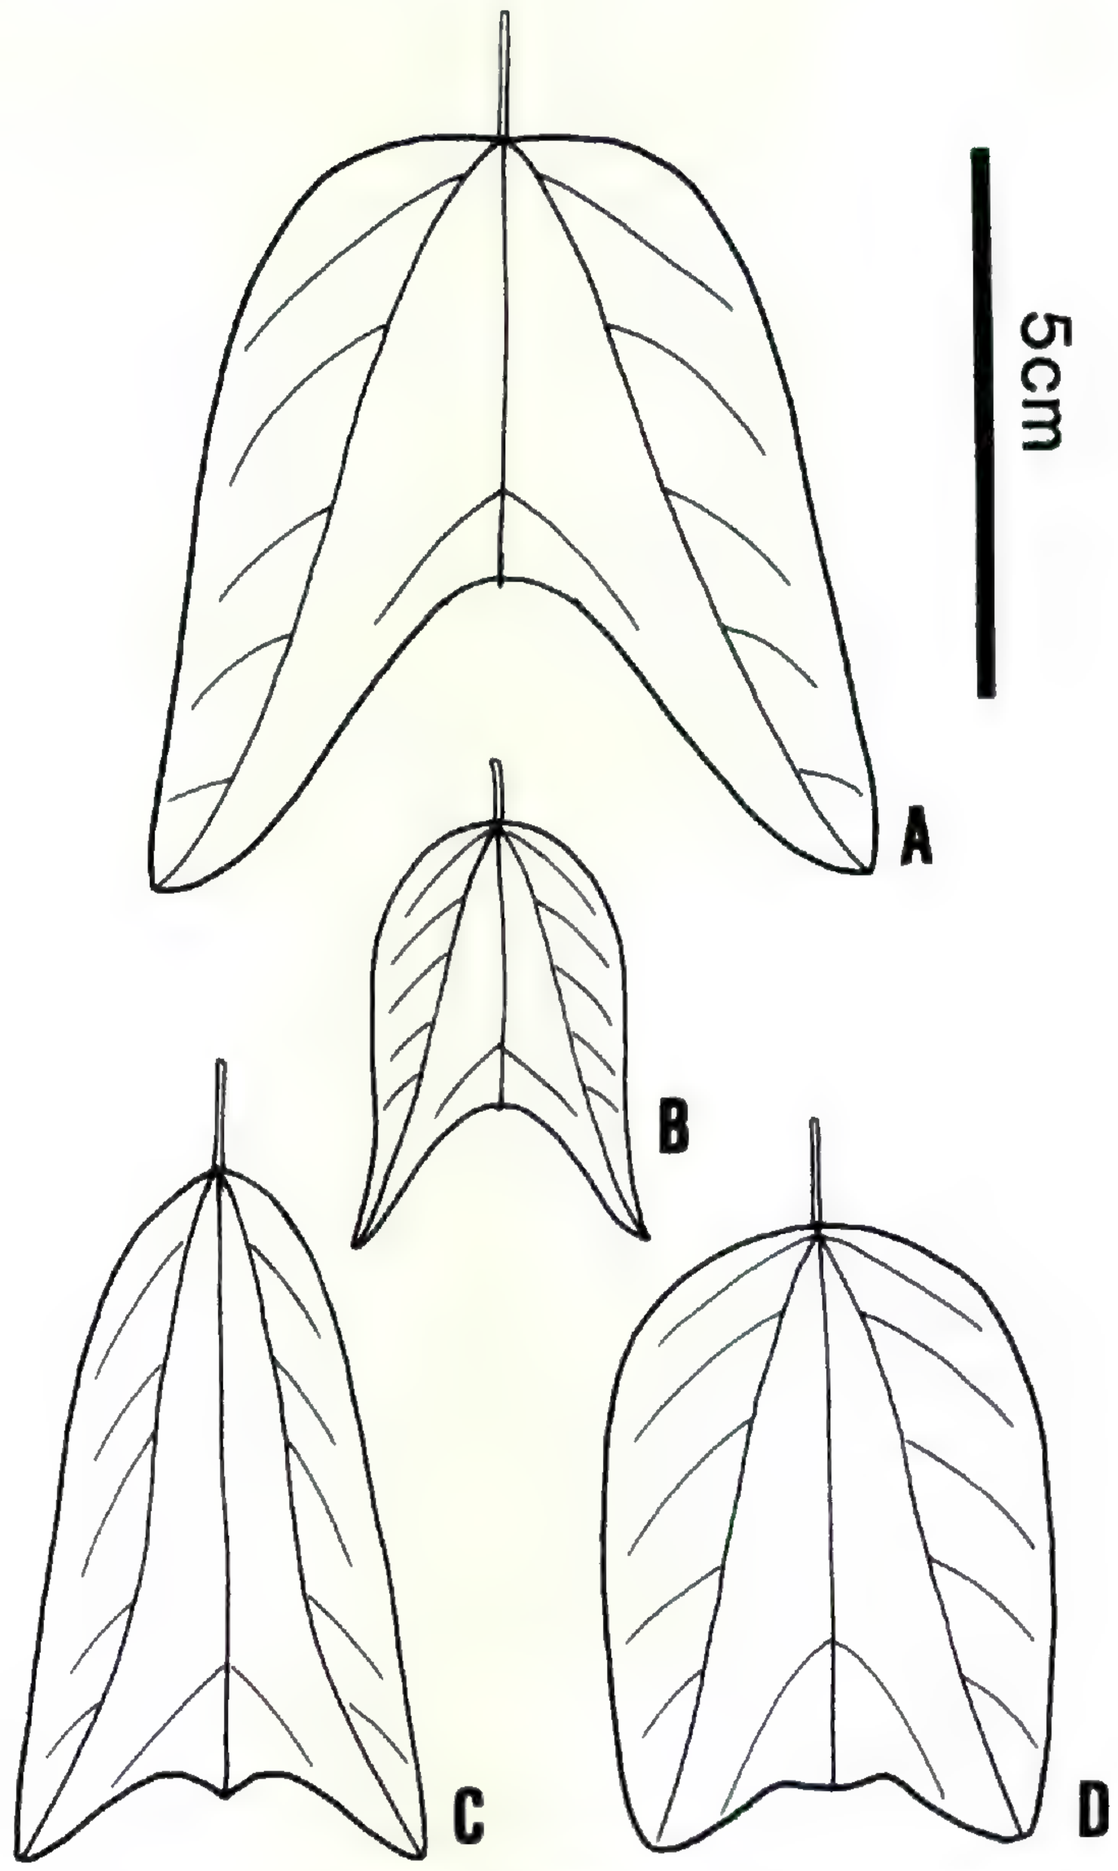

FIGURE 1. Variation in shape of leaves of *Passiflora citrina*.—A. *Molina 5826*.—B. *Molina & Molina 14086*.—C. *Molina & Molina 26057*.—D. *Molina & Molina 31167*.

Passiflora citrina may be referred to subg. *Plectostemma* sect. *Xerogona* because of the subpentangular stem, absence of petiolar or laminar nectaries, absence or near absence of floral bracts, elongate fruits with six keels, and seeds with a transversely grooved sclerotesta having a chalazal beak that is sharply angled towards the raphe. Mature fruits are unknown; however, a fruit that is probably of full size with nearly mature seeds is found on the isotype at NY. On a different collection, *Howard et al. 637*, the collector observed the fruits to be "red," but no fruits are included with the specimens. It is unknown whether the fruit

of this species is six-valvately dehiscent, as is usual in the other members of sect. *Xerogona*.

Passiflora citrina is remarkable for its elongate yellow flowers that are tubular in the basal half. The androgynophore is distinctively long and sets the species apart from all other members of sect. *Xerogona* except *P. sanguinolenta* Masters from southern Ecuador. Though very similar to *P. citrina*, *P. sanguinolenta* has nearly triangular stems, peduncles solitary at the nodes, pink to purplish red flowers that retain a diminutive second series of coronal filaments, and seeds with slightly rugulose ridges. Both species have slightly elongate flowers of similar morphology, flowers that have departed from the usual bowl-shaped hymenopteran-adapted groundplan in sect. *Xerogona* (Lindman, 1906) by reduction and fusion of the coronal filaments and partial connation and adnation of the perianth. In *P. citrina* the sepals are free from each other to within 2–6 mm of their bases, but they are submarginally adnate to the edges of the petals; the petals, in turn, are adnate to the connate portion of the coronal filaments. The net effect is a cylindrical structure formed by the adnation of the basal half of the perianth to the tubular and basally connate coronal filaments. The coronal filaments are free only in the distal 3–6 mm and are usually not visible on herbarium sheets without dissection. In dissected and living specimens, I could detect no trace of a second series of coronal filaments near the operculum.

The derived floral morphology of *P. sanguinolenta* is related to a shift in pollinators: the species is primarily hummingbird pollinated in its native habitat (C. Hofmann, pers. comm.). It is probable that *P. citrina* has also shifted away from pollination by hymenopterans.

The butterfly *Heliconius charitonius* was observed using *MacDougal et al. 3048* as a host plant.

Floral bracts are fundamentally absent in *P. citrina*, but in *Molina 6510* the peduncles occasionally bear a single bract at the apex.

This species was first identified as undescribed while the author was a National Science Foundation Fellow at Duke University, and I gratefully acknowledge the financial support of the NSF, the assistance of the curators from the herbaria cited above, and Donald E. Stone for inspiration and guidance during my doctoral studies. The Jessie Smith Noyes Foundation generously provided postdoctoral support for research on Passifloraceae at the Missouri Botanical Garden.

A NEW SPECIES OF *STRYPHNODENDRON* (FABACEAE: MIMOSOIDEAE) FROM AMAZONIAN ECUADOR

Stryphnodendron Mart. (Fabaceae: Mimosoideae) is a genus of 25 known species, primarily Brazilian in distribution. It is well represented in Amazonia by forest trees and in the Brazilian cerrado region by shrubby species (Occhioni Martins, 1974, 1981; Occhioni, in prep.). Recent collections by the senior author and associates in eastern Ecuador, in the course of fieldwork for a floristic study of the trees of the region, have revealed a new species of *Stryphnodendron* at the western edge of the Amazon basin and in the adjacent foothills of the Andes.

Stryphnodendron porcatum Neill & Occhioni f., sp. nov. TYPE: Ecuador. Napo: 1 km N of Coca, Tropical Moist Forest, alluvial soil, floodplain near mouth of Río Coca, secondary forest and pasture, 250 m, 00°25′S; 77°00′W, 15 Sep. 1986 (fl, frt), *David Neill & Walter Palacios 7359* (holotype, QCNE; isotypes, MO, RFA, QCA, QAME, AAU, NY, K, GB, US, about 10 additional isotypes to be distributed). Figure 1.

Stryphnodendro guianensi (Aubl.) Benth. subsp. *glanduloso* Forero foliis simile, sed calyce et corollae lobis aureopubescentibus recedit; a speciebus ceteris epicarpii ornamento, ordinatione irregulare cristarum in fructus valvis differt.

Trees attaining 40 m with trunk to 60 cm diam. Outer bark grayish brown, lenticellate. Young branchlets, inflorescence axis, and petioles with minute dense brown scurfy tomentum. Leaves 15–16(–22) cm long; petiole terete, puberulent 3.5–5.0 cm, with a 1-mm verruciform gland about 2.5 cm from its base; rachis villous 11–12(–18) cm, with rounded glands between the distal 5–8 pairs of pinnae. Pinnae 11–13 pairs, opposite or subopposite, 5–6(–9) cm long, with small rounded glands between the pairs of leaflets, excepting the 2–3 basal pairs. Leaflets 10–13-jugate (6–7-jugate in the proximal 1–2 pinnae), alternate, elliptic, 6–10(–14) × 3–4(–5) mm, the apex retuse or slightly emarginate, the base unequal; venation inconspicuous; upper surface glabrous, lustrous; lower surface sparsely and evenly villous, the midrib and margins more densely so, with a dense tuft of villi near the base of the blade; margins slightly revolute and thickened; petiolules 0.5 mm, villous. Inflorescence spicate, cylindric, axillary, solitary or 2 together; peduncle terete, brown-scurfy, 1–1.5 cm long; rachis densely pubescent, 5–8 cm long. Flowers hermaphroditic, or sometimes all staminate, 3.5–4 mm long, bracts conchiform, deciduous. Calyx cupular, 1 mm with 5 deltoid lobes, densely golden pubescent. Corolla narrowly campanulate, 2–2.5 mm; lobes acute, 1 mm; basal half of corolla glabrous or with a few scattered golden hairs, the lobes densely golden pubescent externally. Stamens 10, free; filaments 3–4 mm; anthers elongate, 0.5 mm, with a stipitate deciduous apical gland. Ovary 1.5 mm, short-stipitate, densely white-pilose; style 2 mm, filiform, glabrous or with a few hairs. Legume subligneous, 10–12(–14) × 2–2.5(–3) cm, slightly curved, dark brown with scurfy epidermis, the epicarp ornamented with a pattern of ridges aligned at an angle from the center of each valve trending proximally toward the edges, forming a repeated, irregular chevron-like pattern. Seeds transverse, ellipsoid-oblong, 8–10 × 5 mm, dark brown, surrounded by sweet gelatinous pulp.

Additional specimens examined. ECUADOR. NAPO: Cañón de Los Monos, 15 km al N de Coca, 250 m, 00°20′S, 77°01′W, 5 Apr. 1985 (frt), *Neill, Baker, Palacios & Zaruma 6365* (MO, QAME, RFA); Estación Experimental INIAP-Payamino, 5 km al N de Coca, Reserva Florística El Chuncho, 250 m, 00°25′S, 77°00′W, 8–11 Aug. 1986 (frt), *Neill, Palacios & Zaruma 7227* (MO, QAME, RFA); 2 km al N de Coca, 250 m, 4 Oct. 1987 (flr), *Neill, Palacios, Cerón & Manning 7837* (MO, QAME); Reserva Biológica Jatun Sacha, Río Napo, 8 km río abajo de Misahuallí, 450 m, 01°08′S, 77°30′W, 2 Oct. 1986 (flr.), *Walter Palacios 1369* (MO, QAME, RFA). PASTAZA: 2 km al NE de Mera, 1,100 m, 01°27′S; 78°06′W (sterile), *Neill, Baker, Palacios & Zaruma 6161* (MO, QAME). MORONA-SANTIAGO: Taisha, 500 m, 02°23′S; 77°30′W, Oct. 1975 (fl, frt), *E. L. Little, Jr. et al. 690* (QAME, US); Sucúa, 1,200–1,500 m, 02°34′S, 78°10′W, 7–9 Oct. 1975 (flr, frt), *E. L. Little, Jr. et al. 670* (QAME, US).

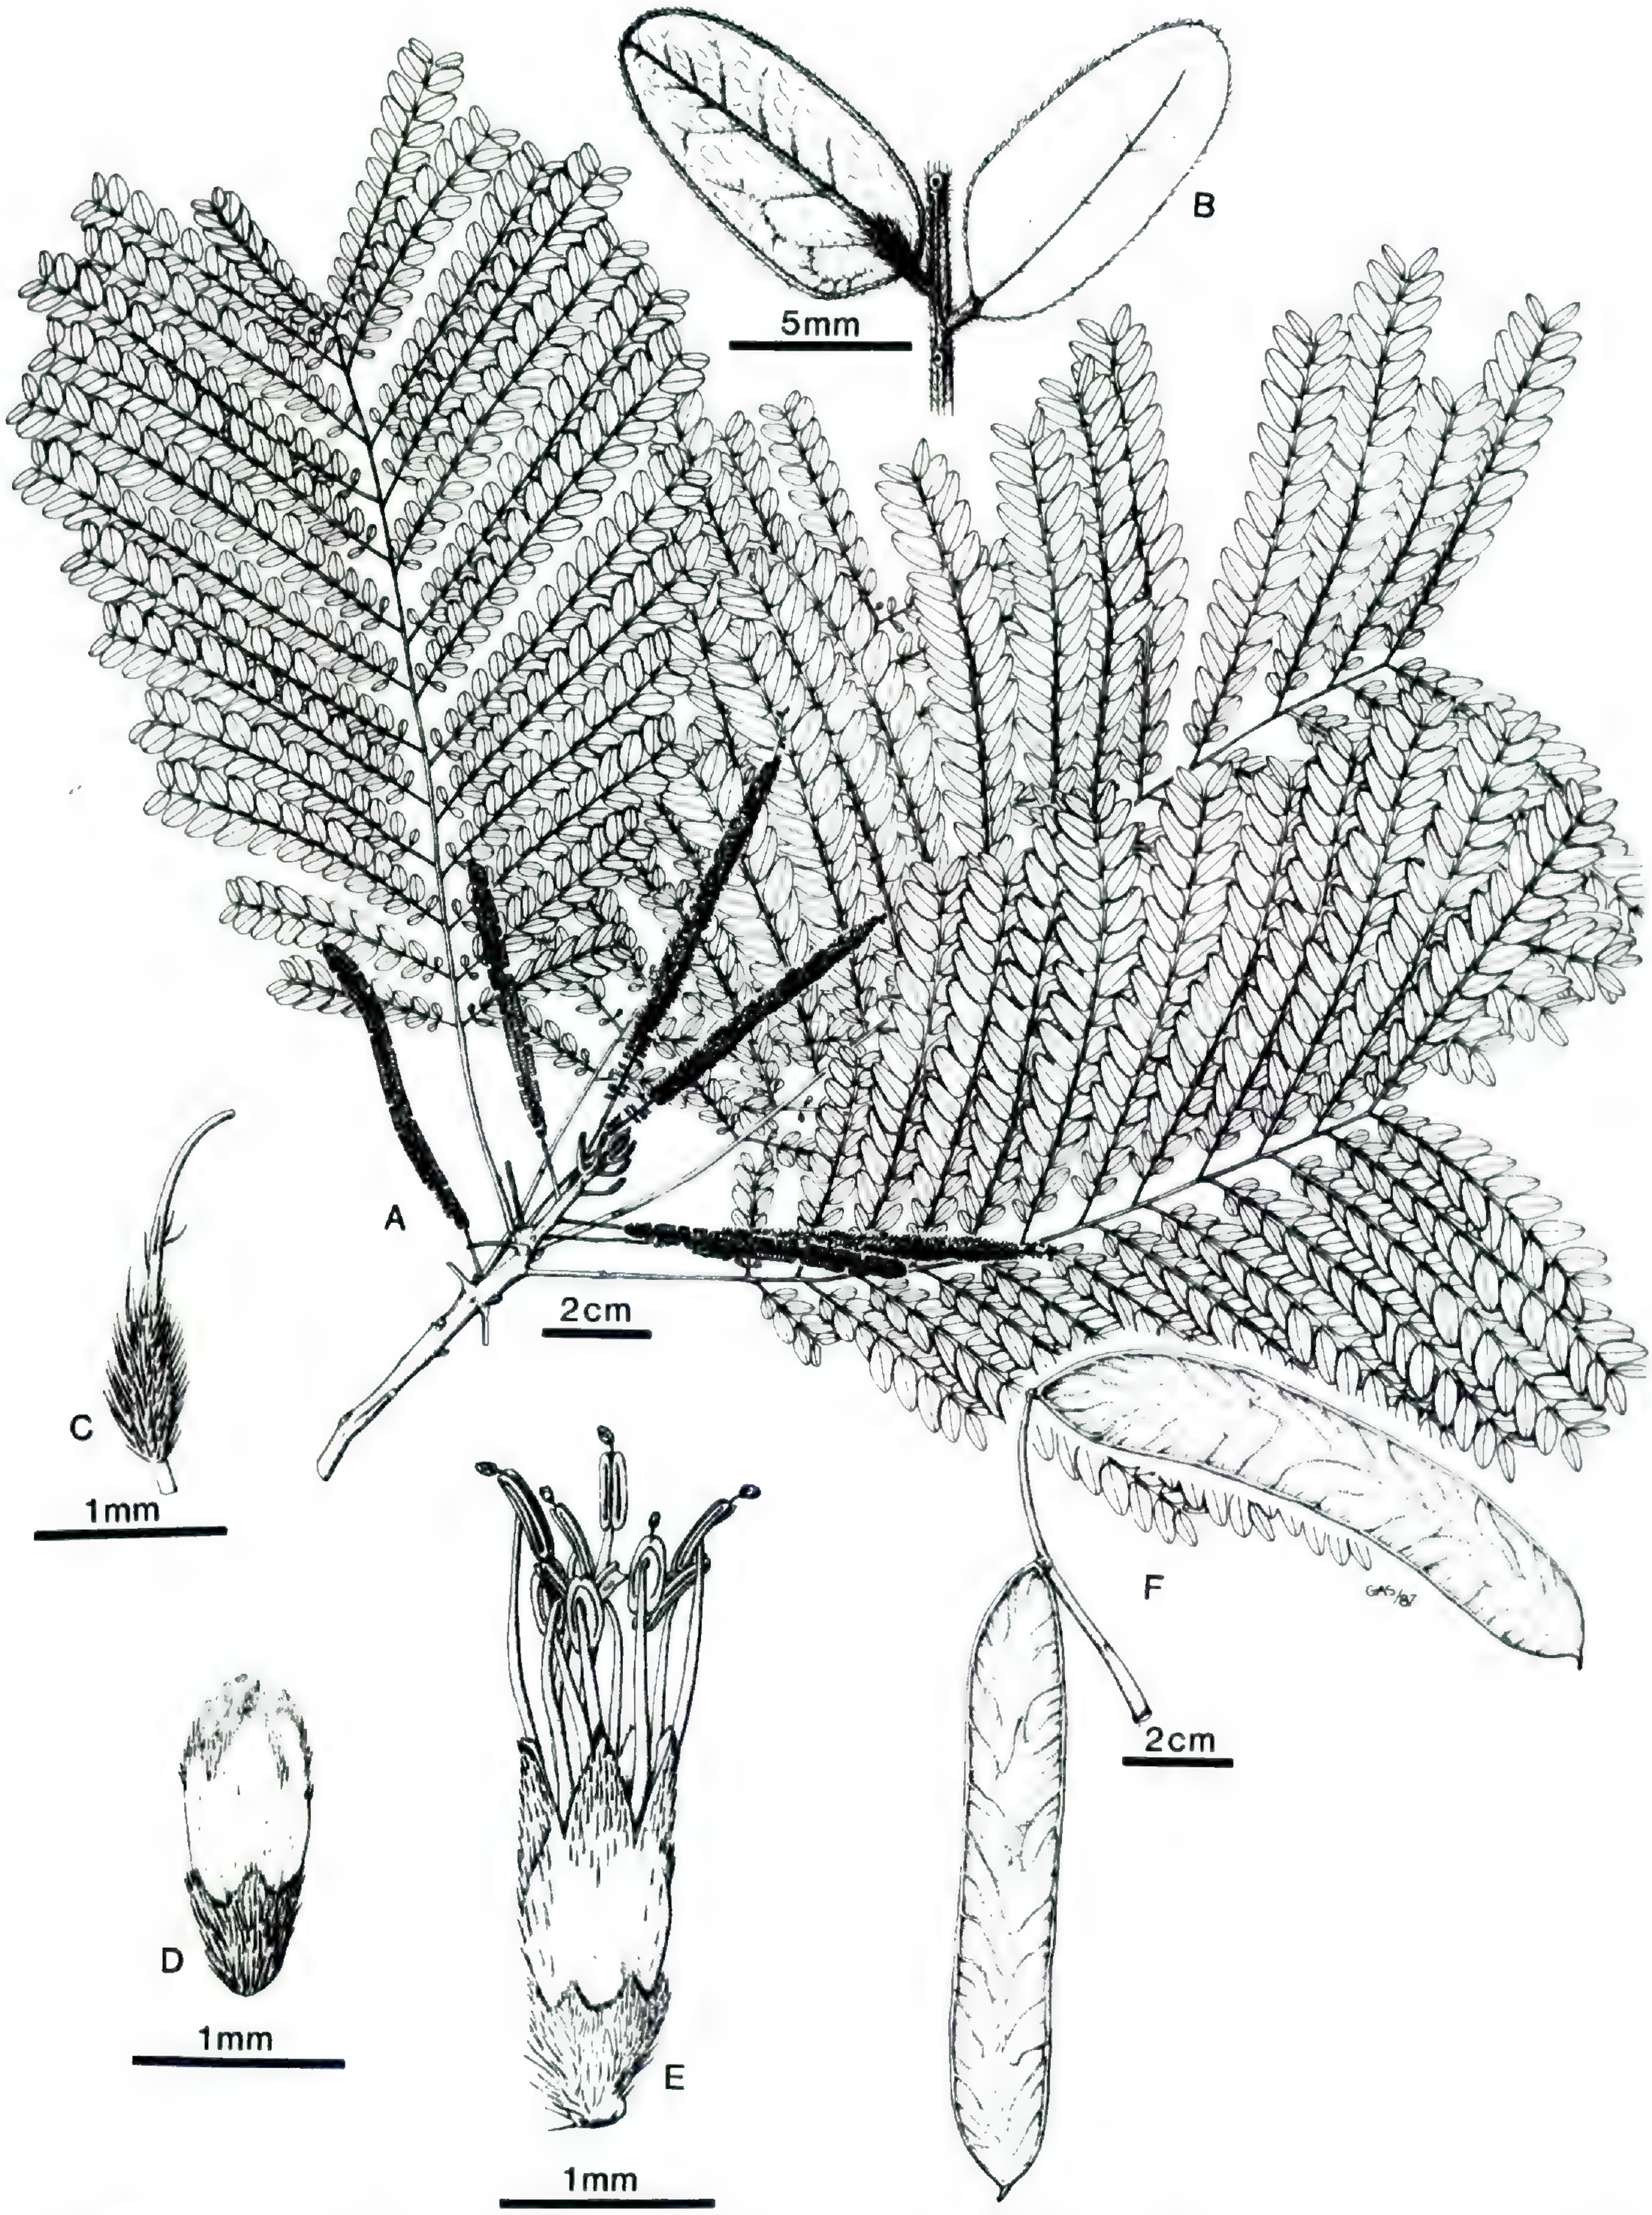

FIGURE 1. *Stryphnodendron porcatum.*—A. Habit.—B. Pair of leaflets, showing upper (right) and lower (left) surfaces, and small glands between each pair of leaflets.—C. Pistil.—D. Flower bud.—E. Open flower.—F. Mature fruits, showing pattern of ridges on epicarp.

Stryphnodendron porcatum is probably most closely allied with *S. guianense* (Aubl.) Benth. subsp. *glandulosum* Forero, known from Peru, Bolivia, and Amazonia in western Brazil, which has similar pubescence of foliage, including the tuft of hairs near the base of the blade, and densely pilose ovary. In *S. guianense* subsp. *glandulosum*, however, the calyx and corolla are short-puberulent externally, whereas in *S. porcatum* the calyx and corolla lobes are densely pubescent with longer, golden hairs, while the corolla tube is nearly glabrous with scattered golden hairs. The typical subspecies of *S. guianense*, which ranges widely in Amazonia and the Guianas, lacks the tuft of hairs at the base of the leaflet blades, and all floral parts are glabrous.

The most distinctive feature of *S. porcatum*, which readily separates it from all other species in the genus, is the striking ornamentation of the legume, an irregular chevron-like pattern of ridges on the surface of the valves. The specific epithet refers to this sculptured surface of the fruits (Latin *porca* = "ridge between two furrows made in plowing"; Stearn, 1966).

Some individuals of *S. porcatum* are evidently female-sterile; the flowers of *Palacios 1369* completely lack pistils.

To our knowledge, this is the first published report of the genus *Stryphnodendron* for Ecuador. No other species are known to occur sympatrically with *S. porcatum* in the Amazon region of the country.

Stryphnodendron porcatum occurs on rich silty alluvial soils of river floodplains, and in Amazonian Ecuador, on upland Oxisol hills up to 1,500 m on the lower slopes of the Andes. In primary forest it attains a height of 40 m with a diameter at breast height of 70 cm. In the region around Coca, Napo Province, Ecuador, *S. porcatum* is also frequent in secondary forests and is often left in pastures after the surrounding forest is cut.

The sweet pulp surrounding the seeds is similar to that of *Prosopis* and *Gleditsia*. Several trees at the INIAP-Payamino agricultural experiment station near Coca stand in experimental pastures established for raising tropical hair sheep. The sheep eat with great relish the *Stryphnodendron* pods that fall to the ground, apparently attracted by the sweet pulp. The new species therefore shows some promise for inclusion in agronomic trials as part of the agroforestry and silvo-pastoral production systems involving sheep, pastures, and forage legumes now being developed for and implemented by settlers in the Napo region of Ecuador.

The support of the U.S. Agency for International Development (USAID) and the Forestry Directorate of the Ecuadorian Ministry of Agriculture, for the research in eastern Ecuador, is gratefully acknowledged. The authors thank Enrique Forero for bringing us together through correspondence, and Alejandro Suárez for preparing the illustration.

A NEW SPECIES OF *HYBANTHUS* (VIOLACEAE) FROM PANAMA

Hybanthus is a very poorly known genus of 150 species of herbs, trees, and shrubs from the Old and New World. The last synopsis of the genus throughout its range enumerated 32 species in the New World (Melchior, 1925); Morton (1944) provided the most recent synopsis of the Central American species. The new species proposed here, *Hybanthus jefensis*, is clearly distinct from all species in Central America and is not placed within any species presently known from Colombia (Smith & Fernández-Pérez, 1954).

Hybanthus jefensis Todzia, sp. nov. TYPE: Panama. Panamá: Cerro Jefe, near Río Indio, 2,100–2,200 ft., 17 Feb. 1968, *Dwyer 1969* (holotype, MO). Figure 1.

Frutices caulibus juvenibus strigulosis; stipulae anguste triangulares in siccitate chartaceae; folia alterna crenulata glabra in siccitate rubropunctata in pagina inferna; inflorescentiae axillares fasciculatae in brachyblastis, floribus 1–4 in pedicellis 1–2 cm longis; petalum panduratum 0.7–1 cm longum rotundatum ad apicem; capsulae 7–8 mm longae.

Shrubs 1–2.5 m tall; older stems terete, reddish brown, glabrous, sparsely branched; younger stems terete to quadrangular, dark to light brown, strigulose with hairs curving upwards, with leaves erect and ± adpressed to stems; stipules narrowly triangular, 1.5–2 mm long, ca. 0.5 mm broad at base, drying chartaceous, brown. Leaves alternate, elliptic to narrowly obovate, 3–12 cm long, 1–3.8 cm broad; petioles terete, 0.5–1 cm long, glabrous; the blade acute at apex, attenuate at base, smooth, glabrous, drying chartaceous with red dots and reticulations beneath, each side with 5–7 usually obscure, gradually arcuate lateral veins; the margin crenulate with 8–17 glandular teeth on each side. Inflorescences 1–4-flowered, axillary, fasciculate on short shoots ca. 2 mm long; bracts inserted at base of pedicels, lanceolate, 1–2 mm long, acute, drying chartaceous, brown; bracteoles on lower half of pedicels 0.5–1 mm long, lanceolate; pedicels 1–2 cm long, slender, glabrous, articulate above the middle. Flowers white, zygomorphic; sepals 5, lanceolate, 2–2.5 mm long, acute, glabrous; lateral petals 4, 4–5 mm long, falcate, with irregularly crenate margins; anterior petal pandurate, 0.7–1 cm long, with claw 4–5 mm long, sparsely pilose, lip 3–5 mm long, 4–5 mm broad at widest point, rounded at apex, glabrous; stamens 5, sessile, free or connate; filaments very short, the anterior 2 stamens with a subglobose gland dorsally; anthers 1–1.5 mm long, sparsely pilose dorsally and at base; connective appendages ca. 2 mm long, 0.5–1 mm broad, rounded at apex, membranaceous; ovary globose, ca. 1 mm long, glabrous, with 3 locules containing 1–2 ovules each; style 2–3 mm long, curved at apex. Capsules loculicidally and elastically 3-valvate, 7–8 mm long, glabrous, with 3–6 seeds, often with persistent style and sepals; seeds globose to ovoid, 2–3 mm diam., smooth, black.

Distribution, habitat, and phenology. Endemic to the Cerro Jefe region of the Prov. Panamá, Panama, at 650–1,000 m elevation in disturbed and undisturbed premontane wet forest. Flowering and fruiting October, November, December, January, and February.

Representative specimens examined. PANAMA. PANAMÁ: region of Cerro Jefe, ca. 1,000 m, 3 Oct. 1969, *Correa et al. 1598* (MO); between Cerro Azul and Cerro Jefe, 24 Dec. 1967, *Dressler 3270* (MO); between Cerro Jefe and La Eneida, 17 Jan. 1968, *Dwyer et al. 8195* (MO); 6.5 km by road N of Lago Cerro Azul, 650–730 m, 13 Jan. 1974, *Nee 9292* (MO).

This species is distinctive by virtue of its small crenulate leaves with red dots and punctations when dried; axillary inflorescences fasciculate on short shoots ca. 2 mm long; stipules that are chartaceous when dry; and pedicels 1–2 mm long. The anterior petal, one of the most diagnostic characters of the genus, is pandurate, 0.7–1 cm long, and rounded apically. In southern Central America *H. jefensis* appears to be most similar to *H. guanacastensis* Standley from which the new species differs by its chartaceous (vs. indurate) stipules, crenulate (vs. doubly serrate) leaf margins, shorter anterior petals (0.7–1 cm long vs. ca. 1.2 cm long), and smaller capsules (0.7–0.8 cm long vs. 1.5–2 cm long). *Hybanthus jefensis* is probably most closely related to *H. sylvicola* Standley & Steyerm. of southern

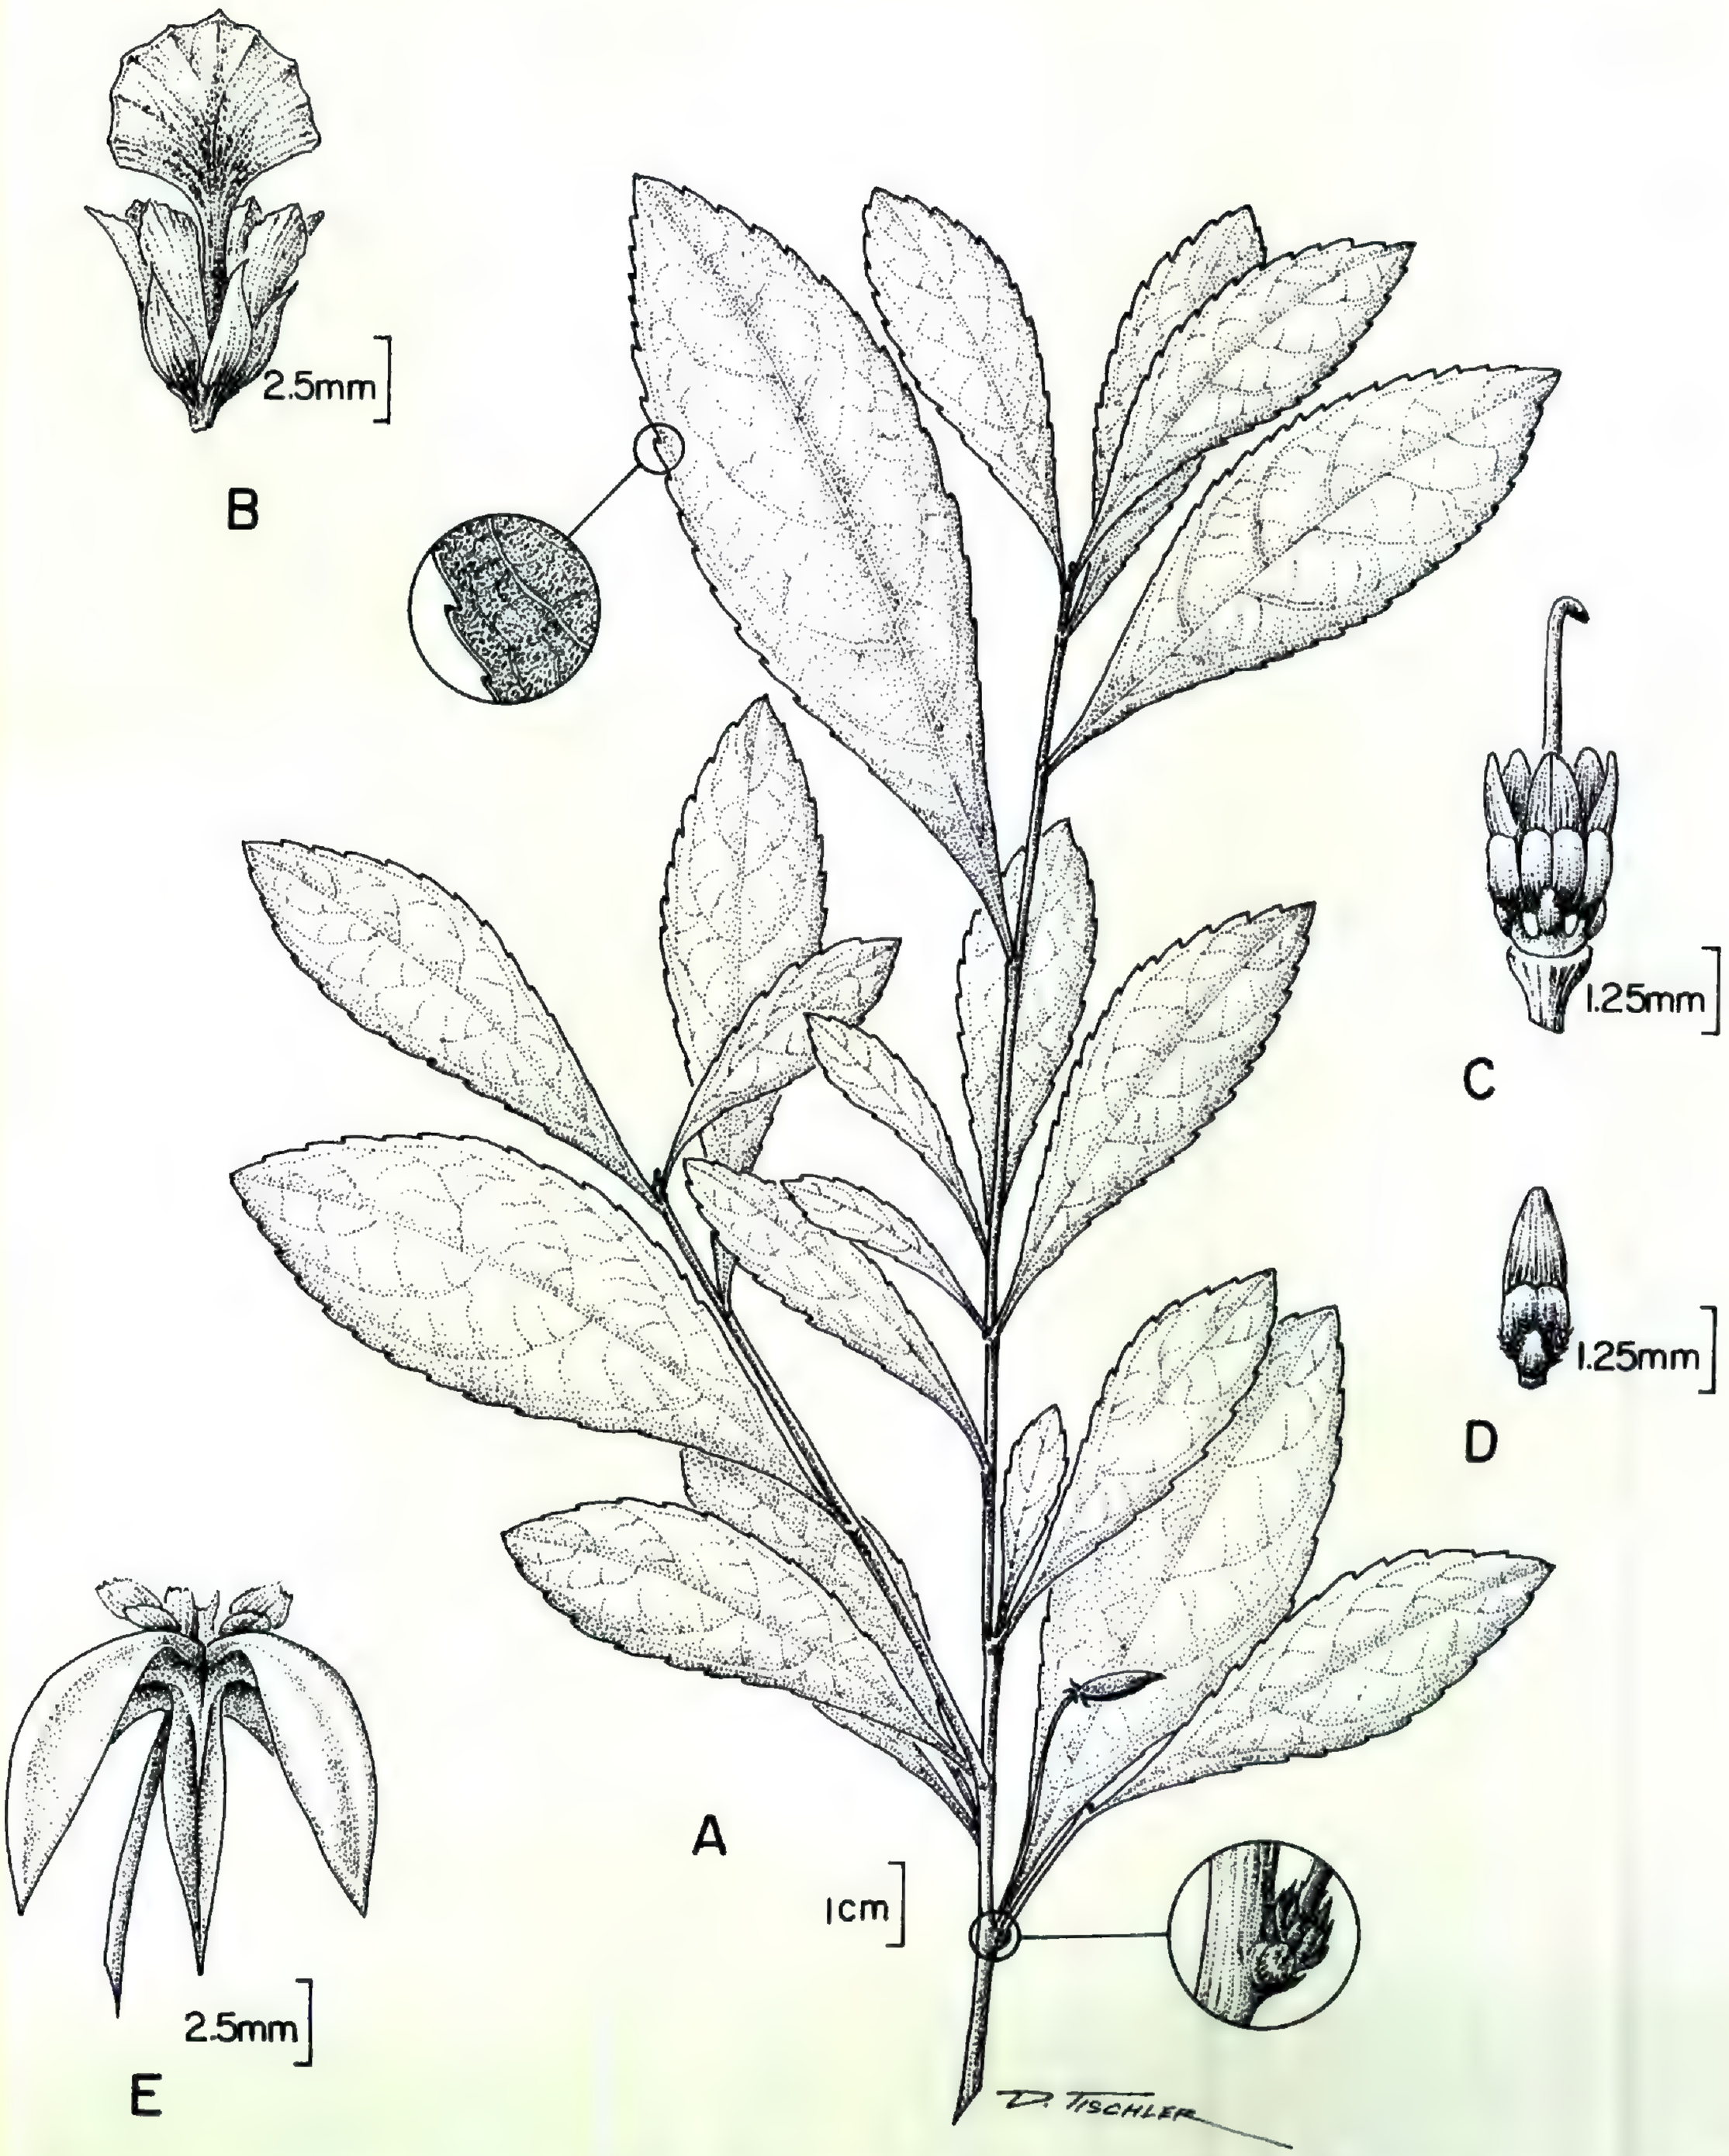

FIGURE 1. *Hybanthus jefensis.*—A. Habit with close-ups of leaf margin and leaf axil showing bracts at base of fascicles.—B. Flower.—C. Close-up of anthers and style with sepals and petals removed.—D. Close-up of an anterior anther. (A–D from *Dwyer 1969.*)—E. Fruit (from *Dwyer 8195*).

Mexico and Guatemala but differs by having strigulose (vs. glabrous) young branches, leaves with (vs. without) red punctations beneath, and lip 0.7–1 cm vs. 1.1–1.3 cm long.

Hybanthus jefensis is yet another endemic to the region of Cerro Jefe in central Panama (Lewis, 1971). In addition to the three *Hybanthus* species reported in the *Flora of Panama* (Robyns, 1967), two other species are presently known from Panama (D'Arcy, 1987; pers. obs).

KEY TO *HYBANTHUS* IN PANAMA

1a. Shrubs or small trees, woody; flowers in fascicles borne on short shoots.
  2a. Shrubs or small trees 1–7 m tall; capsules 0.7–2 cm long.
    3a. Stipules drying white, indurate; leaves sharply serrate, drying uniform in color beneath, without red dots; anterior petal 1.2–4 cm long; capsules 1–2 cm long.
      4a. Anterior petal up to 4 cm long; capsules 1.5–2 cm long; seeds 4–5 mm long ..... *H. prunifolius*
      4b. Anterior petal ca. 1.2 cm long; capsules 1–1.3 cm long; seeds 2–3 mm long ..... *H. guanacastensis*
    3b. Stipules drying brown, chartaceous; leaves crenulate, drying with red dots and reticulations beneath; anterior petal 0.7–1 cm long; capsules 0.7–0.8 cm long ..... *H. jefensis*
  2b. Shrubs less than 1 m tall; capsules 0.3–0.6 cm long ..... *H. galeottii*
1b. Annual or perennial herbs, not woody; flowers solitary, not borne on short shoots.
  5a. Leaves opposite to subopposite at base, elliptic to lanceolate, long-attenuate at apex; plants annual ..... *H. attenuatus*
  5b. Leaves alternate, ovate to oblong-ovate, acute at apex; plants perennial ..... *H. thiemii*

I thank Guy Nesom for providing the Latin description, Doris Lee Tischler for the handsome illustration, and James W. Grimes, George Rogers, and Henk van der Werff for reviewing the manuscript. This work was supported by a Noyes Foundation grant to the Missouri Botanical Garden.

BOOK REVIEW

Mora-Osejo, Luis Eduardo. 1987. *Estudios Morfológicos, Autoecológicos y Sistemáticos en Angiospermas*. Academia Colombiana de Ciencias Exactas, Físicas y Naturales, Serie Jorge Alvarez Lleras 1: 1–195. Retail price: $15.00. (Available from Dr. L. E. Mora-Osejo, Academia Colombiana de Ciencias Exactas, Físicas y Naturales, Apartado Aéreo 44763, Bogotá D.E. 1, Colombia.)

Morphological, Autecological and Systematic Studies in Angiosperms is an important addition to the increasing botanical literature of high scientific quality being produced in Latin America. It has been published by the Colombian Academy of Sciences as the first volume of a new series called "Serie Jorge Alvarez Lleras." The actual text is 188 pages long, with 75 figures, including several color photographs, and a bibliography with over 90 citations. The text is divided into two parts. The first part deals with the morphological and autecological studies and includes five chapters (1–5), while the second deals with the systematic studies and is made up of one chapter (6).

The author indicates that one of his objectives is to present to a broader audience the "typological" method, which has been developed in Germany but is not well known among Spanish- and English-speaking phytomorphologists. In the first chapter he discusses the general principles of the typological method, including such concepts as homology, position, continuity, similarity, etc.; the procedures employed in the study of specific problems; the contribution of typology to our understanding of the organization and architecture of the angiosperms; and the relationship of typology with taxonomy and phylogeny. In Chapter 2, the typological theory and its relation to the evolution of the inflorescence is discussed. Chapter 3 deals with new concepts developed by the author on the diversity and evolution of organizational patterns found in the floral meristems in angiosperms, based on his observations of a number of families, including Melastomataceae, Araliaceae, Bignoniaceae, Asteraceae, Cyperaceae, Juncaceae, Poaceae, Bromeliaceae, and Scheuchzeriaceae. Chapters 4 and 5 deal with the author's original typological studies in *Lilaea*, *Triglochin*, and *Scheuchzeria*, which include the study of the architecture of the meristem and its correlation with the reproductive strategies of these plant groups. In Chapter 6, Mora-Osejo gives an example of the applicability of the typological method to the taxonomic study of *Oreobolus* R. Br., a genus of Cyperaceae.

There are several aspects of this publication that I find outstanding, the most important being the thorough discussion of the theory and practice of the typological method. The author explains how this method allows for a comparative analysis of architectural patterns in plants as opposed to a purely descriptive analysis. The method also allows for interpretation of information derived from the detailed analysis of plant structures through the understanding of the interconnections among them. At the same time, it provides valuable tools for understanding adaptations to the environment as well as reproductive strategies in angiosperms.

Aside from its obvious scientific value, the reader is also very favorably impressed by the good quality of the printed product and by the quantity and quality of the illustrations, which include numerous schematic representations, color and black and white photographs, details of plant parts, and more.

The volume is a substantial contribution to our understanding of this important subject, as are most of Professor Mora-Osejo's publications. His study of the biology of the Haloragaceae, published as part of his treatment of the family for the *Flora de Colombia*, is another example of his scientific excellence. It is to be expected that this volume will be given proper consideration by phytomorphologists in the United States and in Latin America. Its contents are well worth careful study. This work is the result of many years of careful research by one of Latin America's most prominent scientists.—Enrique Forero, *Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri 63166, U.S.A.*

NOTICES

The 1988 Jesse M. Greenman Award

The 1988 Jesse M. Greenman Award has been won by John H. Wiersema for his publication "A Monograph of *Nymphaea* Subgenus *Hydrocallis* (Nymphaeaceae)," which appeared in Systematic Botany Monographs, volume 16. This monograph is derived from a Ph.D. dissertation submitted to the University of Alabama, under the direction of Dr. Robert R. Haynes. Dr. Wiersema based his classification on numerical taxonomy, scanning electron microscopy of seeds and pollen, chromosome numbers, floral biology, artificial hybridization, flavonoid chemistry, and general morphology. Fourteen species are recognized in the subgenus, which is restricted to the American tropics and subtropics, and one new subspecies is proposed.

This Award is named for Jesse More Greenman (1867–1951), who was curator of the Missouri Botanical Garden Herbarium from 1919 until 1943. A cash prize of $250 is presented each year by the Garden, recognizing the paper judged best in vascular plant or bryophyte systematics based on a doctoral dissertation that was published during the previous year.

Nominations for papers published during 1988 are now being accepted for the 21st annual award, which will be presented in the summer of 1989. Reprints of such papers should be sent to: Greenman Award Committee, Research Division, Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri 63166-0299, U.S.A. In order to be considered for the 1989 award, reprints must be received by June 1, 1989.

Reprints

Copies of "The Genus Xyris (Xyridaceae) in Venezuela and Contiguous Northern South America" (Ann. Missouri Bot. Gard. 75: 522–722. 1988) can be obtained by sending $15.00 to: Dr. Robert Kral, Herbarium, Box 1705, Station B, Vanderbilt University, Nashville, Tennessee 37235, U.S.A.

Volume 75, Number 4, pp. 1169–1670 of the Annals of the Missouri Botanical Garden was published on 8 March 1989.

Tropical florulas

Recognizing the utility of floras of restricted tropical areas to workers in a variety of biological disciplines, Missouri Botanical Garden staff members have produced several during the past few years. Available titles are:

La Flora de Jauneche

C. H. Dodson, A. H. Gentry & F. M. Valverde

This is the first in a series of florulas of the life zones of Ecuador. It treats the plants of the Jauneche field station, located in tropical moist forest between Quito and Guayaquil, at an altitude of 50–70 meters. The station occupies 130 hectares and has a known flora of 728 species. All are treated, and each is illustrated with a line drawing of its habit and details of critical features. The book is bilingual: all information is in both English and Spanish.

xxxix + 512 pages, 184 plates, 14 figures; soft bound. Published by Banco Central de Ecuador. 1986. $25.00

Flora of the Río Palenque Science Center

C. H. Dodson & A. H. Gentry

This flora is similar in plan to the Jauneche work, but it treats more species, about 1100. The Río Palenque station occupies 167 hectares at an altitude of 150–220 meters in the tropical rainforest life zone.

xxx + 628 pages, 278 plates, 22 figures; soft bound. Published as Selbyana, vol. 4, 1978. $35.00

Flora of Barro Colorado Island

Thomas B. Croat

About 1350 species of vascular plants are described and many illustrated from Barro Colorado Island, the Smithsonian Institution's 15.6 sq. km reserve in the Panama Canal. "Croat's well-executed effort sets the precedent for the kind of work perquisite to fuller understanding." David Barrington, *Plant Science Bulletin.*

ix + 943 pages, illustrated. Stanford University Press. 1978. $60.00.

To place an order, use this form or a photocopy of it. U.S. shipments: add $1.50 for one book and $.50 for each additional book; non-U.S. shipments: check or money order in U.S. funds, payable to U.S. bank; add $2.50 for one book and $.50 for each additional book. Orders should be prepaid; a $1.00 fee will be added to orders requiring invoices. No shipments are made until payment is received. Mail form with your check or money order, payable to Missouri Botanical Garden, to:

NEW SPECIES AND COMBINATIONS IN TROPICAL AMERICAN *POLYSTICHUM* (DRYOPTERIDACEAE)[1]

David S. Barrington[2]

ABSTRACT

A taxonomic history for the fern genus *Polystichum* in Latin America and an analysis of the important characters at the species level in the genus provide the context for the recognition of new and overlooked taxa. Three new species are described from Latin America, and a new combination is provided for a *Polystichum* species from the southern Andes.

In the course of preparing a treatment of the genus *Polystichum* for the *Flora Mesoamericana*, I have discerned a set of new and neglected species from Central America and the northern Andes, which I report here. The species now included in the genus *Polystichum* have only once been included in a monograph (Mettenius, 1858); there has been no modern monographic work on the genus in the New World. An inquiry into species and speciation phenomena in Costa Rica (Barrington, 1985a, b; Barrington, et al., 1986) has led in turn to an inquiry into the significance of hybrids with respect to species concepts in the ferns (Barrington et al., in press). I report here on the morphological characters important in distinguishing species of Latin American *Polystichum*. This review of characters provides the context for the descriptions of species, which make up the central contribution of this work.

TAXONOMIC HISTORY

The genus *Polystichum* Roth, terrestrial ferns characterized by fastigiate leaves with inequilateral leaf segments and peltate indusia (when present), is prominent and diverse in montane regions

[1] I thank Luis Diego Gómez P. for his energy and support of my fieldwork in the Sierra Talamanca, Steven R. Hill for his critical reading of the Latin descriptions, and Lynn Bohs for her thorough review of the manuscript. Several nomenclatural and taxonomic problems were resolved with Rolla Tryon's help. The curators of the following herbaria supported this project through loan of materials: A, AAU, CR, ENCB, F, GH, MO, NY, UC, US, USNA, YU. The University of Vermont provided support for laboratory and fieldwork through its Institutional Grants BRSG-79 and BSCI85-1.

[2] Pringle Herbarium, Department of Botany, University of Vermont, Burlington, Vermont 05405-0086, U.S.A.

throughout the world. The generic name originates with Roth (1799), but it was K. B. Presl (1836) who first circumscribed the genus as it is now recognized. The most important influence on the taxonomic history of *Polystichum* was the treatment of W. J. Hooker (1862), in which most of the twice-pinnate taxa in the world were combined into one species. As a result, the morphological and taxonomic diversity of species was left unstudied by the otherwise productive taxonomists of the late nineteenth century. Christensen (1906) maintained Hooker's counterproductive species concept in *Polystichum*, which has perpetuated the tendency for taxonomists to ignore the diversity of twice-pinnate species. Christensen did recognize 41 forms, many of which were associated with names whose types represent distinct species.

Latin America and eastern Asia are the two centers of diversity for the genus *Polystichum*. Although the diversity and biology of species are well known in Asia (Tagawa, 1940; Daigobo, 1972), we know little about the genus in the New World tropics. Maxon (1909) was the first to recognize natural species in the American tropics, but his work was confined to the West Indies. Only recently (A. R. Smith, 1981; Stolze, 1981) has similar progress been made in defining the continental species. In the past few years, the extent of the taxonomic problem has become clear with the demonstration of extensive hybridization and allopolyploidy in the American tropics (Barrington, 1985a, b; Barrington et al., 1986). I reviewed the present taxonomic status of the genus *Polystichum* in Latin America (Barrington, 1985c).

Morphology

The analysis leading to the descriptions of the new species provided here and the work on hybridization and polyploidy have revealed the most useful characters for delineating *Polystichum* species in Latin America. Since there has been no previous morphological review for the genus in the Neotropics, I provide an analysis of the important characters for *Polystichum*. I have also commented on ontogenetic and environmentally induced variation, which is unusually confusing in the genus.

Indument

Indument in *Polystichum* consists entirely of scales and scale homologs (squamules and microscales); true hairs, bristles, and spines are absent, at least in Latin American species. The general form, texture, and frequency of scales are important in delineating taxa of *Polystichum*. Particularly important are histological features of the scales: they may be conform (sensu Tryon, 1970) or they may have a margin of cells different in shape and orientation from the scale body. Scale color is important too, although variable with position on the plant and age of the plant. Tagawa (1940) contended that the smallest scales on the abaxial lamina surface (the microscales) are important in defining subgeneric groups in *Polystichum*. In Latin America, variation in microscales is extremely conservative, consistent with Tagawa's contention. Most species have the acicular microscales typical of sect. *Metapolystichum*.

I have followed Smith (1981) in describing the processes that arise from the edges of scales and squamules as cilia, although this is an oversimplification. In fact, scales and squamules bear a continuum of processes from cilia (long and delicate) to setae (short and stiff). I have chosen to call all of these processes cilia and use adjectives to describe their length and stiffness. The kinds and proportions of these cilia on the different scales and squamules are important taxonomic characters in *Polystichum*.

Lamina

The dissection and texture of the lamina provide critical characters for distinguishing species of *Polystichum*, although they are phenotypically and ontogenetically variable. Particularly confusing is the tendency for older plants to have larger, more dissected leaves. Nevertheless, species can be circumscribed within the context of the ontogenetic variation encountered. In addition, the shape, angle of attachment, and revoluteness of leaf segments (pinnae and pinnules) are all important, although phenotypically variable (especially revoluteness). Development of the spinules (extensions of vein tips) varies among species. The complex interaction of ontogeny, environment, and genotype that shapes *Polystichum* leaves perhaps explains the recognition of large, poorly resolved taxa by both Hooker and Christensen.

Sori and Sporangia

The placement of the sorus relative to the vein tips is important in *Polystichum*, even though it is variable across a segment. Indusium presence or absence is an important character, although the indusium is sometimes deciduous in neotropical *Polystichum* species. In addition, the diameter, shape, and histology of the indusium vary among, but usually not within, species. Color is sometimes use-

ful but is variable with age. The design of the perispore is usually constant within species.

Color of the indument is a useful character in *Polystichum*, as in many ferns. The color names used in the descriptions here are the National Bureau of Standards color names as defined in *National Bureau of Standards Special Publication 440* (and its predecessor, *Circular 553*), evaluated by comparison of indument with the ISCC-NBS Color-Name Chart (a supplement to *NBS Special Publication 440*), which is a partial set of color chips representing the color centroid. I standardize color terminology in this way, rather than using the Ridgway-Dade terminology and standardization (Stearn, 1983), because those color names are much less familiar, and the color chips on which they are based are much harder to locate. Indument is variable and systematically useful in all three dimensions of the color centroid (hue, value, and chroma); it is also variable in these dimensions with position on the plant and age of the individual.

Hybridization and Species Definition

Hybrids between the new Costa Rican species described here and several other species were encountered during fieldwork. Several of these hybrids have been described elsewhere (Barrington, 1985a, b). All of them meet two criteria of hybridity: intermediacy and spore irregularity. Since all of the hybrids have irregular spores, they are probably sterile and hence provide evidence of species-level divergence between their progenitors (Barrington et al., in press). This evidence provides a first working hypothesis for species definition in tropical American *Polystichum* and the basis for recognizing the new species described here.

Descriptions of New Species

Polystichum concinnum Lellinger ex Barrington, sp. nov. TYPE: Costa Rica. San José: Villa Mills, S of Pan American Highway about one km E of Hotel La Georgina, ca. 3,100 m, 3 Jan. 1980, *D. S. Barrington 694* (holotype, GH; isotype, VT). Figure 1.

Filix grandis terrestris. Caudex erectus base ascendente. Squamae petiolorum anguste lanceolatae, coriaceae, badiae, pallidomarginatae, cilia proximalia squamarum petiolorum longa tenuiaque, distalia brevia, indurata, saepe processibus recurvatis unciformibus. Lamina 0.4–2.0+ m longa, bipinnata, indumento paginae rhachidis abaxialis constans e squamis lanceolatis umbrinis. Pinnae patentes attenuatae, pinnis medianis circa 7–18 cm longis. Pinnulae crenatae patentes fere planae vix spinulosae circa 0.8 cm longae 0.4 cm latae, squamis minimis acicularibus, pallidibus. Sorus terminalis in ramo acroscopico venae locatus, indusio peltato circa 0.5–0.7 mm diametro.

Plant terrestrial, the spreading-ascendent leaves to 2 m long. Stem erect from an ascendent base, sometimes with weak lateral branches. Petiole with 8 vascular bundles, 2 large adaxial and 6 small abaxial; petiole scales narrow-lanceolate, coriaceous, conform, blackish red to dark reddish brown with sharply delimited narrow lighter borders, the color transition to border abrupt; the proximal cilia frequent, long and delicate, the distal cilia scattered, short, indurate, often with recurved hooklike processes. Petiole squamules unguiculate and deltate, wrinkled, very dark red with deep orange borders, with cilia scattered on the unguiculate squamules to dense on the deltate squamules. Lamina 0.4 to more than 2 m long, chartaceous, acuminate, 2-pinnate, abaxial rachis scales strong brown, ciliate and lanceolate to sparsely ciliate and unguiculate. Pinnae ca. 20–35 on each side of the rachis, attached at right angles to the rachis, attenuate, the median pinnae ca. 7–18 cm long, basal pinnae about $\frac{9}{10}$ as long; pinna-rachis squamules strong brown, sparsely ciliate, lanceolate or rarely unguiculate. Pinnules ca. 10–25 on each side of the pinna rachis, attached at nearly right angles to the pinna rachis, flat, truncate at the base and obtuse to rounded, crenulate (the basal acroscopic pinnules of each pinna often pinnatisect above the auricle), weakly spinulose, about 0.8 cm long and 0.4 cm wide, the basal pinnules of each pinna abruptly shorter than the next distal pinnules; microscales of costules and veins acicular, pale, without glandular cells. Sorus terminal on an acroscopic vein branch, covered by a thin, peltate, casually deciduous indusium ca. 0.5–0.7 mm diam., the indusium flange of cubical to radially elongate, slightly sinuate cells organized into radial files, the indusium-flange margin a single row of narrow, radially elongate cells. Spores with a well-developed cristate perispore.

Distribution. Endemic to high, wet forests of the Sierra Talamanca, Costa Rica and Panamá, 2,000–3,000 m, occasionally to 3,400 m in disturbed areas above treeline.

The affinity of this large, graceful species is with the large group of indusiate and two-pinnate species most diverse in southern Mexico. *Polystichum concinnum* is most similar to two Mexican species, *P. rachichlaena* Fée and *P. erythrosorum* A. R. Smith: all three are large indusiate, flat-leaved, two-pinnate species with crenate pinnules, and they are

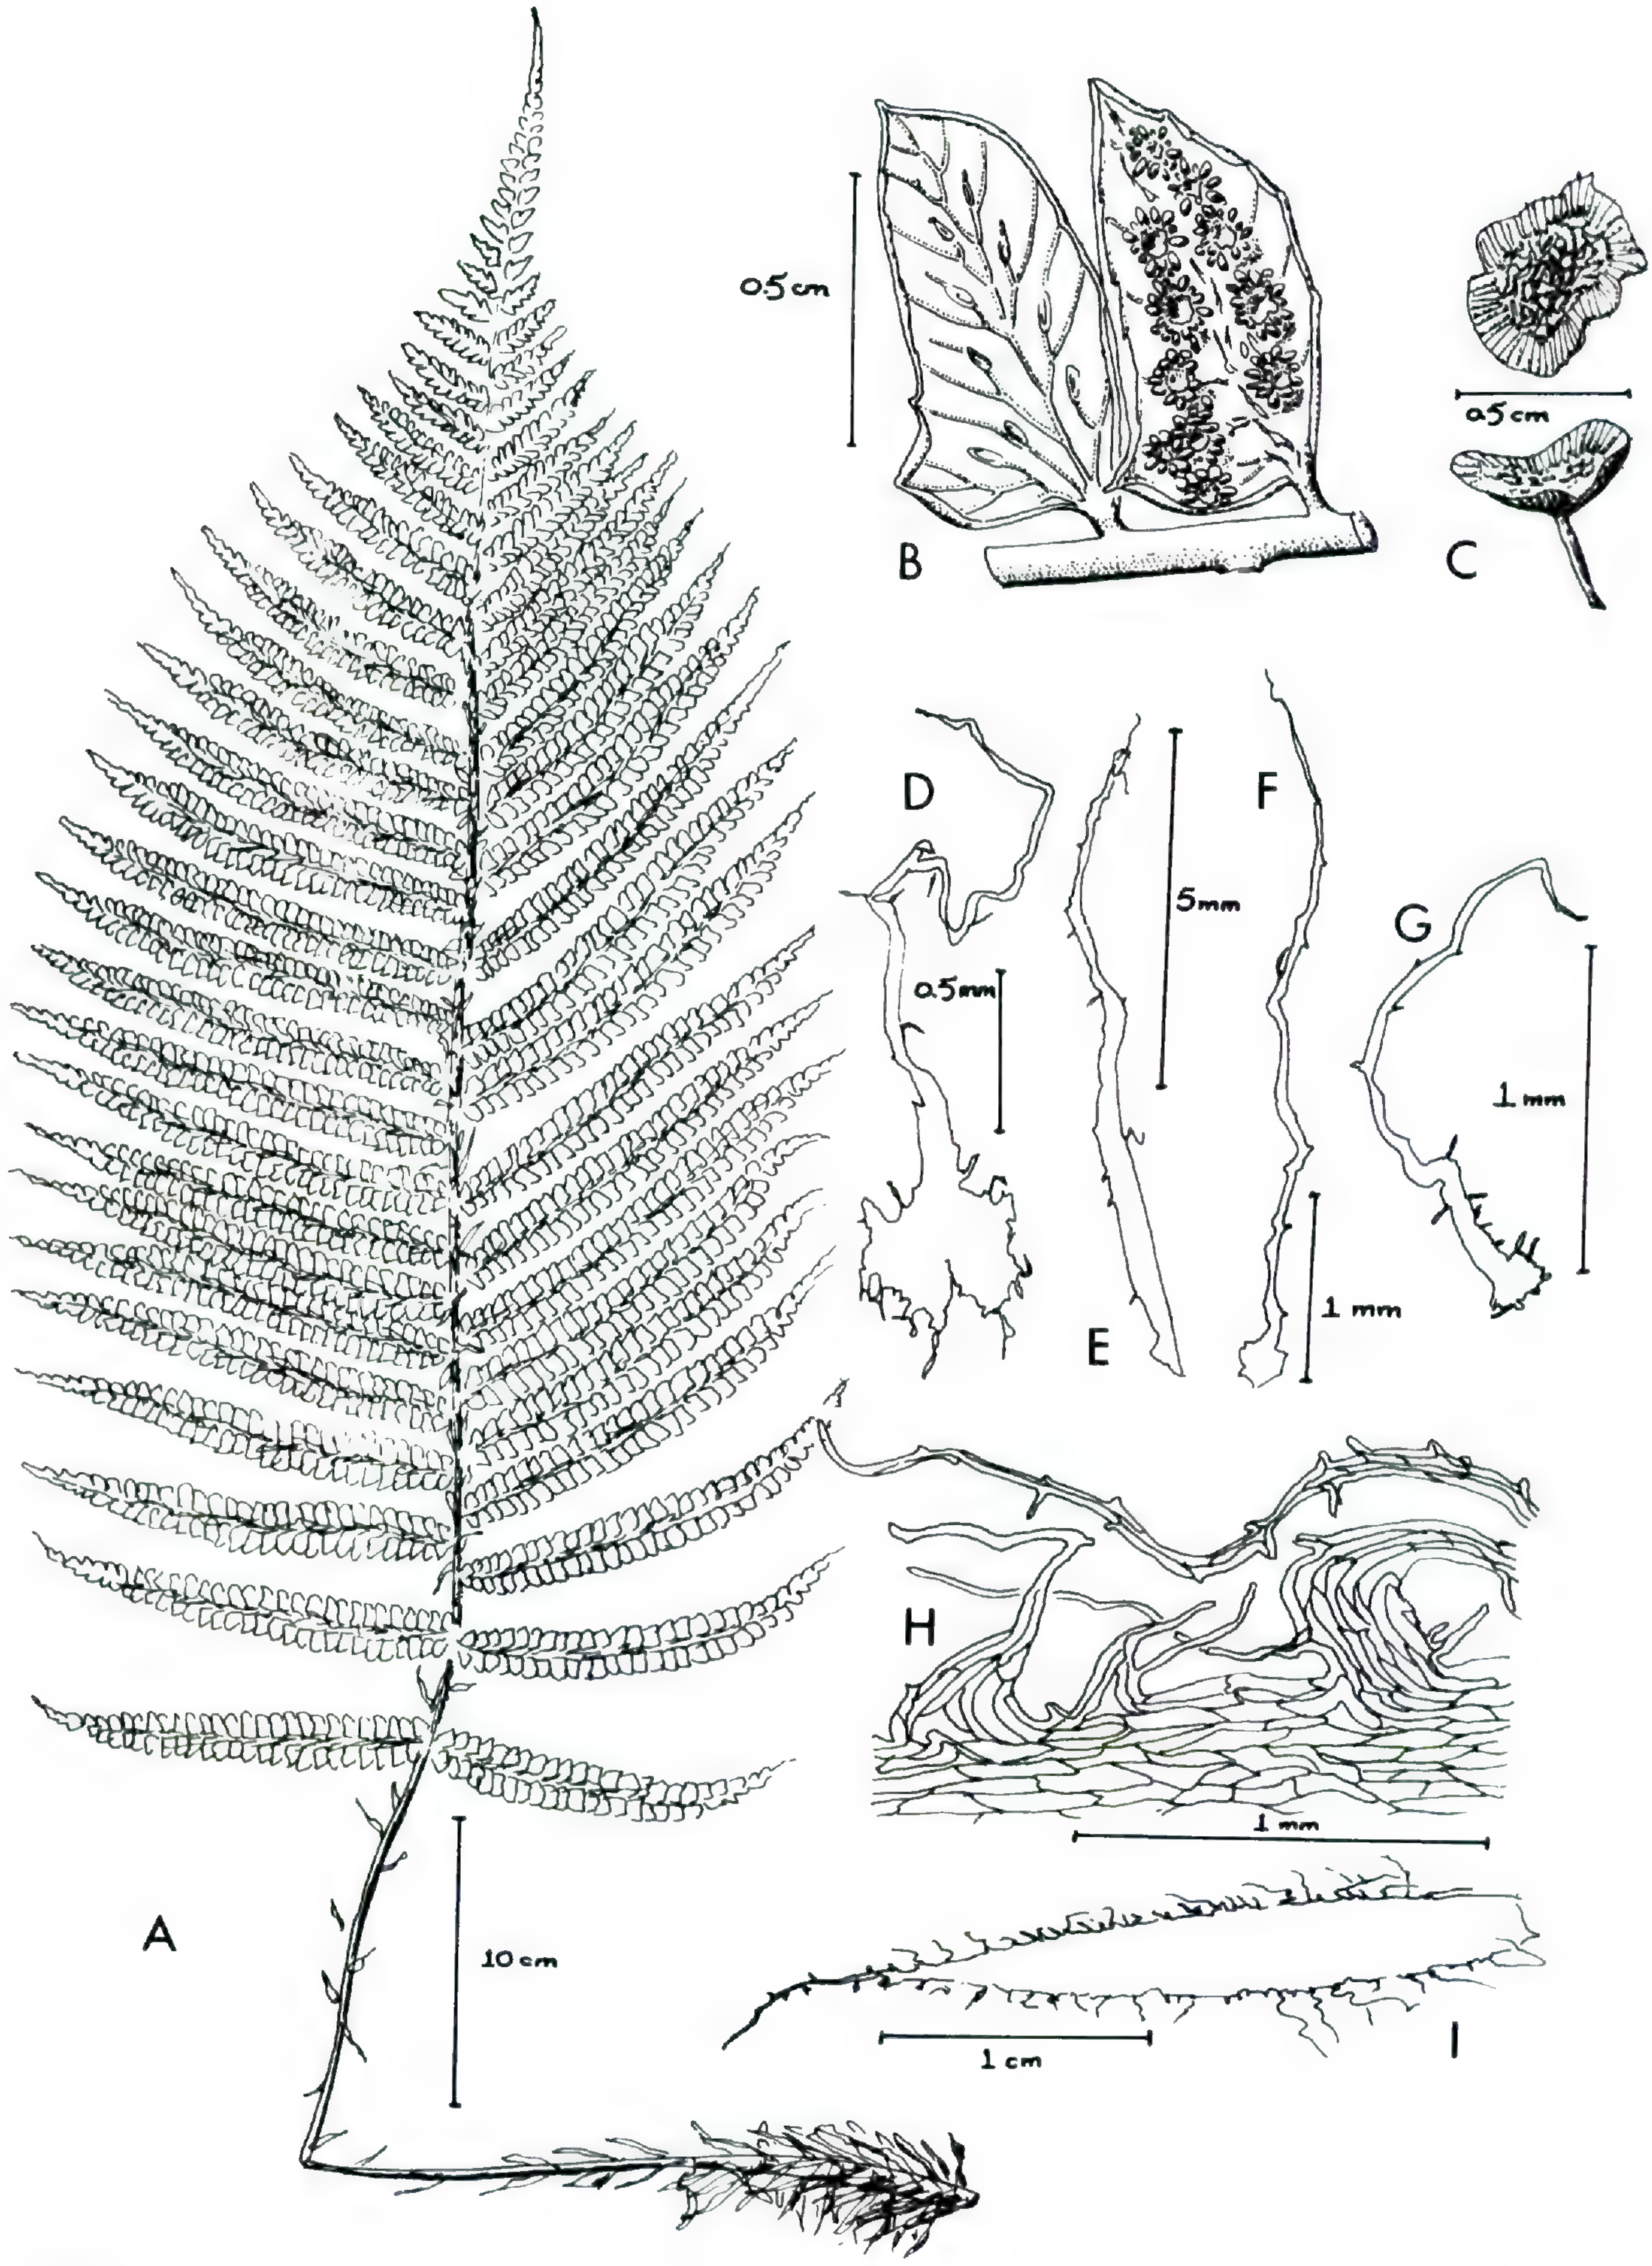

FIGURE 1. *Polystichum concinnum.*—A. Leaf.—B. Two pinnules, the left one with sori removed.—C. Indusium, from above (upper) and side.—D. Rachis scale.—E, F. Rachis squamules.—G. Pinna-rachis squamule.—H. Medial edge of petiole scale (below), petiole scale apex.—I. Petiole scale.

all confined to high-altitude forests. *Polystichum rachichlaena* is notable for the large size (over 1 mm diam.) and persistence of its indusia; it also has petiole scales virtually devoid of cilia. The lamina and sorus of *P. concinnum* are similar to those of *P. erythrosorum*, but the petiole scales of *P. erythrosorum* are broader, marginate, and strongly bicolorous (basally lustrous and black with brownish orange borders). In addition, the long, delicate cilia of *P. concinnum* are lacking in *P. erythrosorum*, and the small distal cilia are not dark and indurated as they are in *P. concinnum*. *Polystichum concinnum* is well represented in herbaria; it has been determined most often as either *Polystichum muricatum* (L.) Fée (which differs in having short petiole-scale cilia) or *Polystichum ordinatum* (Kunze) Liebm. (which differs in having narrow leaf bases and strongly bicolorous petiole scales with thick bases).

David B. Lellinger, of the United States National Herbarium, first distinguished *P. concinnum* and coined its species epithet.

Several chromosome counts of plants from the Talamanca range yielded $n = 41$ pairs at meiosis I.

Additional specimens examined. COSTA RICA. CARTAGO: Villa Mills, 1 km N of Restaurant La Georgina, 30 May 1978, *Barrington 576* (GH, VT). SAN JOSÉ: Cerro Chirripó, SW slopes, along ridge trail from Canaan to summit, 8,500–10,000 ft., 22 & 27 Aug. 1967, *Evans, Lellinger & Bowers 73* (US). PANAMA. CHIRIQUÍ: Cuesta de Las Palmas, southern slope of Cerro de la Horqueta, 1,700–2,100 m, 18 Mar. 1911, *Maxon 5527* (US).

Hybrids. Hybrids between this species and the distinctive *P. speciosissimum* have been collected four times from roadcuts on the Pan-American Highway in the Sierra Talamanca area of Costa Rica (*Barrington 705, 1274, 1516*, VT; *W. D. Stevens 14317*, MO). Hybrids with the following species are discussed under that taxon.

Polystichum talamancanum Barrington, sp. nov. TYPE: Costa Rica. Cartago: Cerro de la Muerte, roadcut 0.4 mi. W of highest point on Pan-American Highway, SE aspect, 3,330 m, 4 Jan. 1980, *D. S. Barrington 708* (holotype, GH; isotypes, CR, VT). Figure 2.

Filix terrestris. Rhizoma repens frondibus fasciculatis. Squamae petiolorum lanceolatae, plerumque papyraceae, luteofuscae, ciliis longis tenuibusque. Lamina foliorum fecundorum 12–70+ cm longa, rigide erecta in locis apricis, indumento paginae rhachidis abaxialis constanti e squamis longilanceolatis croceis. Pinnae ascendentes acuminatae vel breviter attenuatae, pinnae medianae circa 5 8 cm longae. Pinnulae patentes fere (70–80° e rhachidi), revolutissimae in locis apricis crescente, vix spinulosae, circa 0.8 cm longae, 0.4–0.5 cm latae, squamis minimis aicularibus pallidis. Sorus terminalis insidens ramo acroscopico venae, indusio genuino nullo vel spathulato, raro peltato, 0.05–0.07 mm lato.

Plant terrestrial, the rigidly erect leaves to 60 cm long. Rhizome short-creeping, with small lateral branches. Petiole with 2 large adaxial and 6 small abaxial vascular bundles; petiole scales lanceolate, herbaceous or rarely chartaceous, conform except at cilia, medially dark yellow-brown, the border similar or distally moderate olive-brown, the color transition to border gradual; the cilia proximally common, long, arising from broad bases of several cells ± perpendicular to the scale axis, thin and delicate; petiole squamules unguiculate, strong brown, ± flat, with broad and short cilia common at base. Lamina of fertile leaves 12 to 70+ cm long, rigidly erect (spreading-erect in shade), lanceolate, 2-pinnate; abaxial rachis scales narrow-lanceolate, uniformly medium to deep orange-yellow, with short cilia throughout and long cilia distally; abaxial rachis squamules like those of the petiole, deep orange, crumpled, the cilia well developed at squamule base. Pinnae about 40 on each side of the pinna rachis, attached at about a 40° angle to the rachis, acuminate to short-attenuate, the median pinnae ca. 5–8 cm long, basal pinnae ½–9/10 as long; abaxial pinna-rachis squamules deep orange with long cilia at the base and scattered short cilia distally, the larger long-lanceolate, the smaller unguiculate. Pinnules ca. 11–14 on each side of the pinna rachis, attached at about a 70–80° angle to the pinna rachis, strongly revolute in sun (only the sides of the pinnules revolute, not the tips), barely revolute in shade, cuneate at base and acute-tipped, crenulate (the basal acroscopic pinnules of each pinna often pinnatisect above the auricle), with spinules only at auricle and pinnule apex, ca. 0.7–0.9 cm long, 0.4–0.5 cm wide (wider at the well-developed auricle), the basal pinnules of a pinna about the same length as the more distal pinnules; microscales acicular, pale, without glandular cells. Sorus terminal (rarely subterminal) on an acroscopic vein branch, without true indusia or less commonly with a spatulate or rarely reniform to peltate indusium 0.05–0.07 mm diam., the spatulate indusia composed of a narrow proximal portion with cells elongate parallel to the axis and a broader distal portion with cells irregularly placed and shaped. Spores with a well-developed long-cristate perispore.

Distribution. Endemic to the subalpine rain-páramo areas and disturbed sites in the tropical

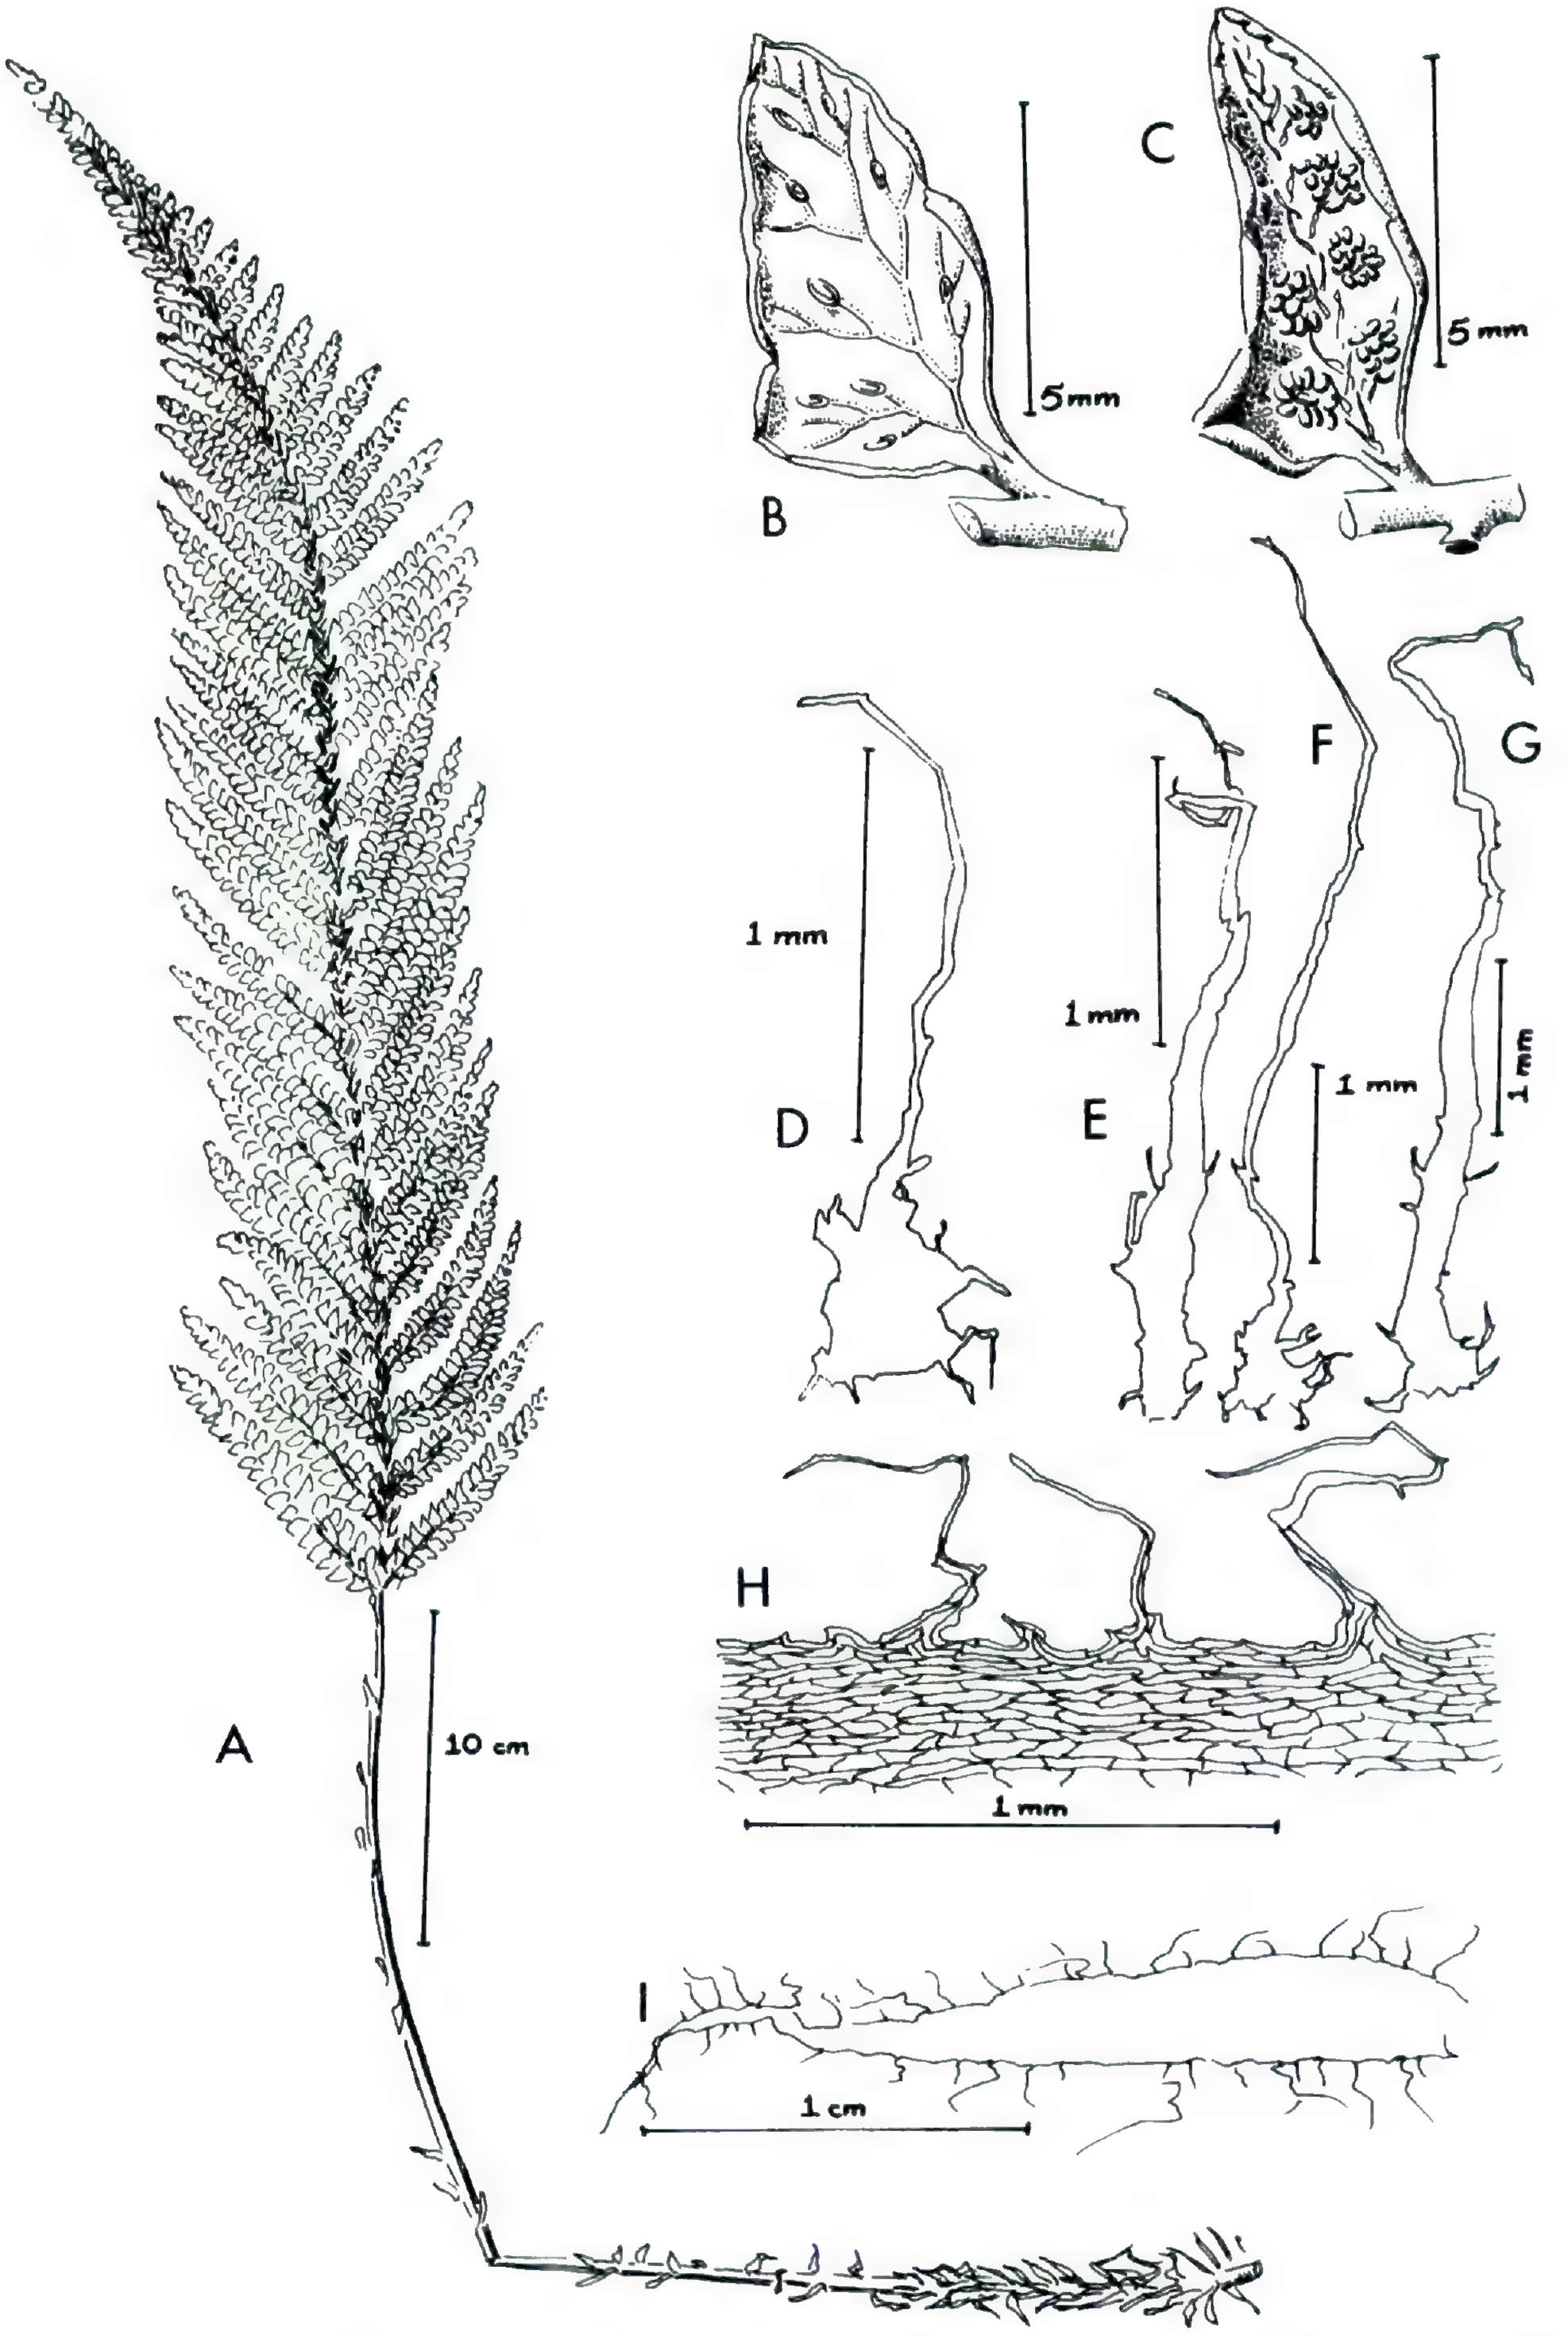

FIGURE 2. *Polystichum talamancanum*.—A. Leaf.—B. Pinnule of plant from shade site, sori removed.—C. Pinnule of plant from sunny site.—D. Petiole squamule.—E, F. Rachis squamules.—G. Pinna-rachis squamule.—H. Medial edge of petiole scale.—I. Petiole scale.

montane rainforest of Costa Rica and western Panamá, 3,000–3,500 m.

Polystichum talamancanum is the allotetraploid derivative of *P. concinnum* (described above) and an unknown diploid species that is also a progenitor of Costa Rican plants of the widespread tetraploid *P. orbiculatum* (Desvaux) Gay (Barrington, 1985b; Barrington et al., 1986, and unpublished data). (*Polystichum orbiculatum* is the

correct name of the widespread Latin American alpine *Polystichum* commonly known as *Polystichum polyphyllum* (Presl) Presl.) *Polystichum talamancanum* is prominent in rock clefts and on roadbanks along the Pan-American Highway above treeline in Costa Rica. It tends to have more patent pinnae and flat pinnules in shade. The indusia are variously developed: some sporophytes never have indusia; others regularly produce spatulate indusia. This variation complicates discrimination of *P. concinnum*, *P. talamancanum*, and their backcross hybrid.

Polystichum talamancanum, endemic to the region above treeline in the Sierra Talamanca, may be confused with *Polystichum orbiculatum* and allied taxa. *Polystichum orbiculatum* in Costa Rica has flaccid petiole scales that are paler and more orange than those of *P. talamancanum* and has long, delicate cilia throughout. In addition, *P. orbiculatum* has apically as well as laterally revolute pinnules, and it is never indusiate, whereas *P. talamancanum* has pinnules that are revolute only laterally and sometimes has indusia.

In the Andes from Venezuela to Peru, an array of plants has been collected from those like *P. orbiculatum* in Costa Rica to plants much like *P. talamancanum*. The Andean plants most like *P. talamancanum* differ from it in lacking indusia and having broader, larger petiole scales with narrow white borders bearing short, stiff cilia; if they are hybrids, their progenitors differ from those of *P. talamancanum* and are best determined as *P. pycnolepis* (Kze. ex Kl.) Mett. The taxonomy and evolution of *P. orbiculatum* and its allies in the Andes is a complex and intriguing problem: the hybrid origin of *P. talamancanum* on the Sierra Talamanca is likely to be one part of a much broader, Andean set of evolutionary events, including the origin of *P. orbiculatum* and other high-altitude *Polystichum* species.

Additional specimens examined. COSTA RICA. CARTAGO: Cerro de la Muerte, Pan-American Highway, 5 km above Millsville (about 8 km above Nivél), Cordillera de Talamanca, 3,400–3,500 m, 25 July 1949, *Holm & Iltis 590* (MO). SAN JOSÉ: Cerro Asunción del Macizo de Buena Vista, 3,325 m, 31 July 1964, *Jiménez M. 2235* (CR). PANAMA. CHIRIQUÍ: summit of Chiriquí Volcano, 3,374 m, 27 Feb. 1918, *Killip 5459* (US).

Hybrids. *Polystichum talamancanum* hybridizes with three species on the Sierra Talamanca in Costa Rica, making recognition of the taxa involved difficult. It hybridizes with its diploid progenitor *P. concinnum* to yield a highly variable triploid backcross, reported by Barrington (1985b) as *P. muricatum* × *P. polyphyllum*. Representative specimens of this hybrid are *Barrington 596*, *719*, and *1278* (all CR, GH, VT), all from Cerro de la Muerte, Costa Rica. In addition, sterile putative hybrids of *P. talamancanum* with *P. orbiculatum* (*Barrington 1283*, CR, GH, VT) and *P. speciosissimum* (*Barrington 1500*, CR, GH, VT) have been collected from disturbed sites above treeline in the Sierra de Talamanca.

Polystichum bulbiferum Barrington, sp. nov.
TYPE: Ecuador. Prov. Zamora-Chinchipe: road Loja–Zamora, km 39, 1,600–1,650 m (79°04′W, 3°59′S), 21 April 1973, *L. Holm-Nielsen, S. Jeppesen, B. Løjtnant & B. Øllgaard 4095* (holotype, AAU). Figure 3.

Filix terrestris. Rhizoma parvum, ascendens. Squamae petiolarum lanceolatae, papyraceae, emarginatae (conformes), umbrinae, ciliis longis tenuibusque. Lamina 0.3–0.4 m longa chartacea, acuminata, pinnata, abaxialiter bulbilo squamato prope apicem praedita; indumentum rhachidis paginae abaxialis constans e squamis parvis filiformibus fuscis. Pinnae patentes, planae, crenatae, falcatae, attenuatae, vix spinulosae; pinnae medianae circa 7 cm longae 1.5 cm latae, indumento rhachidis pinnae constanti e squamulis numerosis filiformibus fuscis sine ciliis, squamis minimis costularum venarumque acicularibus pallidis. Sorus abaxialis, in venis acroscopicis fasciculi venarum.

Plant terrestrial. Stem ca. 0.5 cm long, 1.0 cm diam., erect from an ascendent base. Petiole scales lanceolate, papyraceous, conform, light yellow-brown, petiole-scale cilia long and delicate; petiole squamules narrow-lanceolate, crumpled, pale orange-yellow, with abundant short cilia. Lamina 0.3–0.4 m long, chartaceous, acuminate, 1-pinnate, with a scale-covered bulbil abaxially near the distal end of the rachis; abaxial rachis scales filiform, deep brown, with very sparse short cilia. Pinnae ca. 15 on each side of the rachis and attached to it at right angles, flat, auriculate, falcate-attenuate, crenate (crenulate to entire above), weakly spinulose at auricle and pinna apex; the median pinnae ca. 7 cm long and 1.5 cm wide, the basal pinnae ca. $\frac{9}{10}$ as long; pinna-rachis squamules abundant, dark brown, filiform, without cilia; microscales of costules and veins acicular, pale, without glandular cells. Sorus abaxial on an acroscopic vein branch, indusia absent. Spores with a well-developed folded perispore.

In its leaf dissection and pinna shape, *Polystichum bulbiferum* resembles the Madagascar species *P. kalambatitrense* Tard. and *P. maevaranense* Tard. Among New World polystichums, it is the only one-pinnate species with bulbils attached below the apex of the leaf. In contrast to the Madagascar species, it is exindusiate, as are all of the polystichums endemic to the northern Andes. The detection of a morphologically distinctive species such

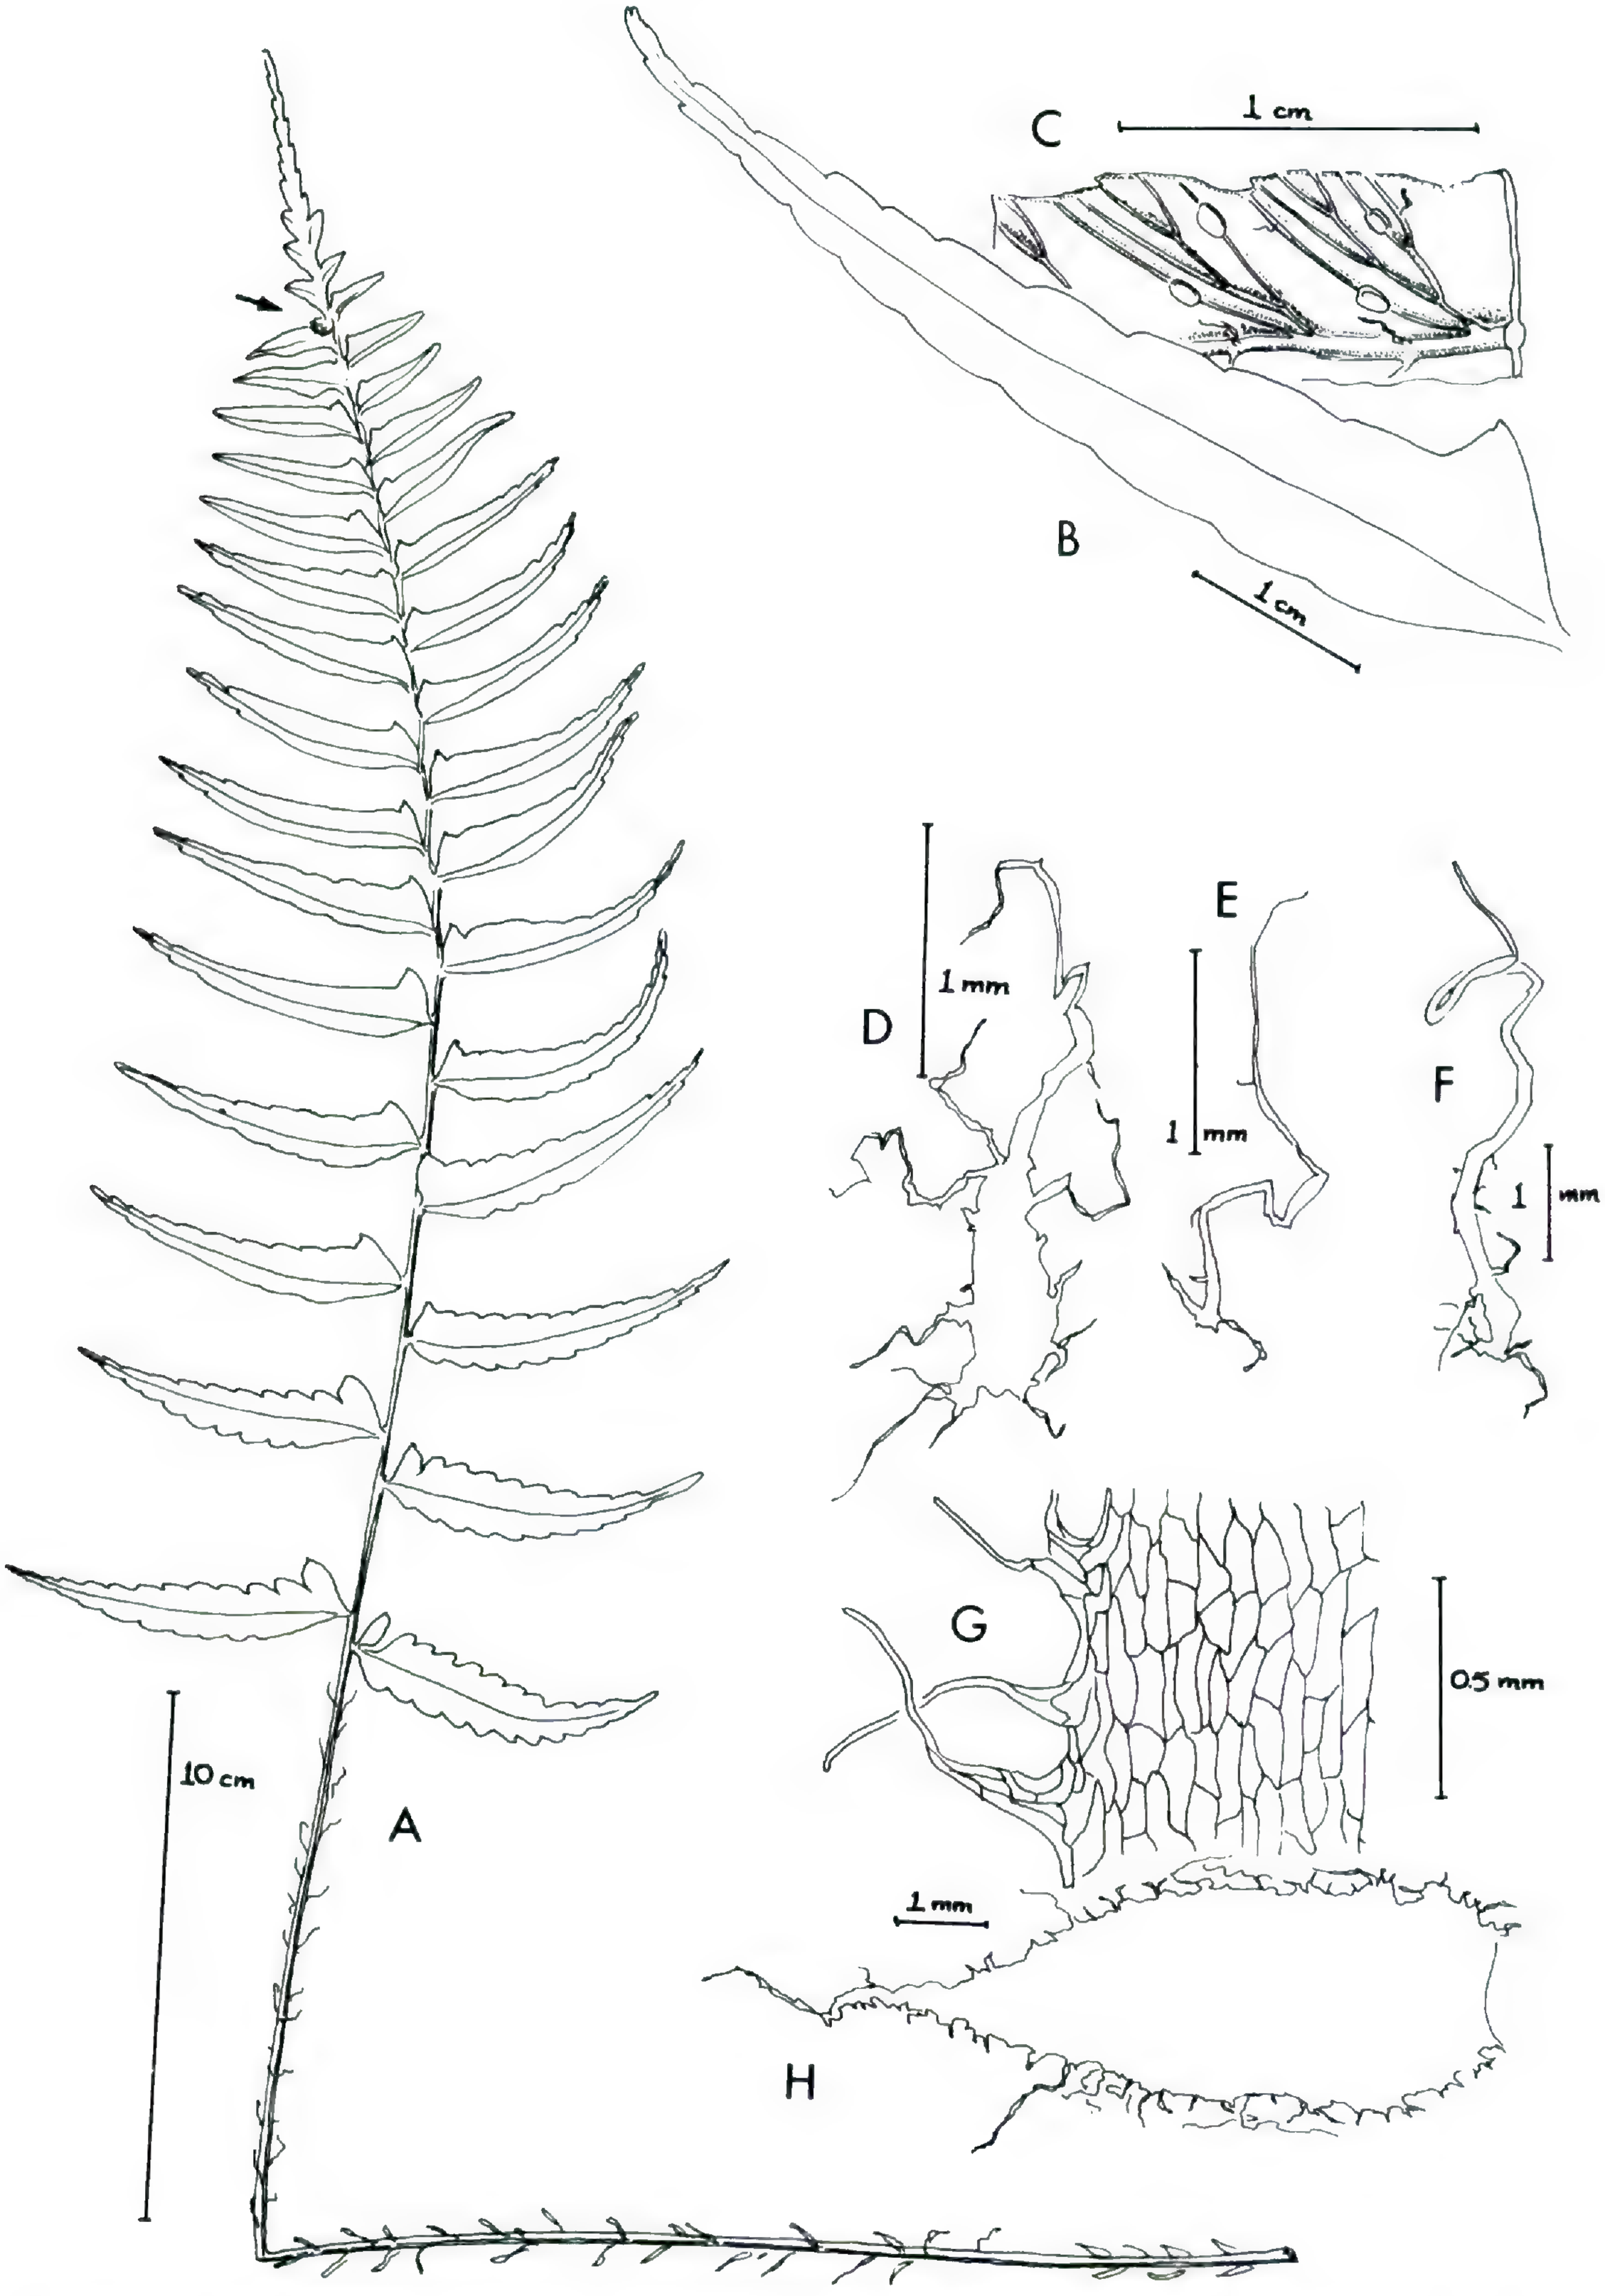

FIGURE 3. *Polystichum bulbiferum.*—A. Leaf with bulbil on rachis (at arrow).—B. Pinna outline.—C. Portion of pinna with sori removed.—D. Petiole squamule.—E, F. Rachis squamules.—G. Medial edge of petiole scale.—H. Petiole scale.

as *P. bulbiferum* only within the last 15 years suggests that major morphological trends in the diversity of the genus in Latin America may still be undocumented by collections, in spite of recent intensive work. This strongly suggests that maintaining substantial collecting programs in tropical forests between 2,000 and 4,000 m is a priority if we are to represent the morphological diversity in this and other genera adapted to the wet montane forests.

Additional specimen examined. ECUADOR. ZAMORA/CHINCHIPE: road between Loja and Zamora, ca. km 29–31, 2–4 km W of Sabanilla, 1,700–1,750 m, 1 Jan. 1979, *Luteyn, Lebrón-Luteyn & McAlpin 6634* (AAU).

NEW COMBINATION

Polystichum subintegerrimum (Hooker & Arnott) Barrington, comb. nov. *Aspidium subintegerrimum* Hooker & Arnott, The Botany of Captain Beechey's Voyage 52. 1832. TYPE: Chile. Bíobío: "Conception" [Concepción], collector unknown (holotype, K).

This distinctive species has black, coriaceous petiole scales, and its two-pinnate leaves have widely spaced pinnae and widely spaced, coriaceous pinnules with auricles pinnatifid only in the basal pinnules of a pinna. It may be well represented in other herbaria besides GH. Some specimens from northern Peru reminiscent of *P. subintegerrimum* have browner petiole scales, more dissected and less coriaceous pinnules, and no indusia. These may be hybrids or a hybrid species including a Peruvian progenitor and *P. subintegerrimum*.

Representative specimens: CHILE. BÍOBÍO: Lonco (Concepción), 22 Sept. 1928, *Espinosa 1, 2, 5* (GH); Concepción, Nov. 1937, *F. Jaffuel 4014* (GH). LA ARAUCANIA (CAUTÍN): Depto. Victoria, along the road to Laguna Malleco, Salto de la Culebra and Laguna Verde, sandy places, 950–1,050 m, 15 Mar. 1939, *J. L. Morrison & R. Wagenknecht 17522* (GH). LOS LAGOS: Chiloe, Fuerte de Ahuí (Ancúd), Jan. 1929, *M. R. Espinosa 7* (GH); Chiloe, Ancúd, Apr. 1868, *R. O. Cunningham s.n.* (GH); Corrál, 6 Oct. 1930, *H. Gunckel 2050* (GH); same locality, 16 Aug. 1930, *H. Gunckel 2082* (GH); Niebla, 13 Dec. 1931, *H. Gunckel 2865* (GH).

Exindusiate specimens: PERU. ANCÁSH: Depto. Yungáy, N side of first lake, Llanganuco, 11,500 ft., 30 July 1960, *S. G. E. Saunders 517* (F); 10 km NE of Yungáy, near Laguna Llanganuco, 3,450 m, 22 Oct. 1965, *Tryon & Tryon 6557* (GH).

NEW OR NOTEWORTHY ORCHIDS FOR THE VENEZUELAN FLORA. VII. ADDITIONS IN *MAXILLARIA* FROM THE VENEZUELAN GUAYANA[1]

Germán Carnevali[2] *and Ivón Ramírez*[2]

ABSTRACT

Two new *Maxillaria* species from the Venezuelan Guayana, *M. foldatsiana* and *M. santanae*, are described and illustrated. One highly variable species, *M. auyantepuiensis*, is discussed, and a new subspecific taxon is proposed. *Maxillaria tenuis* is noted as a new record for the Venezuelan flora.

Maxillaria Ruiz & Pavón is the largest genus of the subtribe Maxillarinae, with about 400–450 species ranging from Mexico and the West Indies to southern Brazil. The genus reaches its highest development in the Andes, but Middle America, southern Brazil, the Amazonian Basin, and the Guayanas are well represented. The species of *Maxillaria* usually grow in places of heavy rainfall but often can be found in places with a marked dry season. They grow in almost every vegetation association and at any elevation from sea level to near the snow line but are especially common in rainforest or cloud forests at 500–2,000 m. Most members of the genus are epiphytic, but it is not unusual to find lithophytic or even terrestrial species, particularly in open, humid places. The vegetative morphology is very variable, ranging from tiny plants less than 1 cm high to plants 2 m long. They are usually pseudobulbous, sympodial plants, but pseudobulbless, almost monopodial species are not unknown. Rhizomes may be short, making caespitose plants, but many species have long creeping primary stems; these may be appressed to substrate for their entire lengths or only attached at their bases to the host, making erect, ascendent, or pendulous plants.

Maxillaria is characterized generically by solitary flowers originating from the pseudobulb base or from the internodes of the rhizome (the *Camaridium* alliance). The flowers may be minute to very large and showy and are variable in many respects, although the column is always basally produced into a more or less well-developed column-foot to which the labellum is hinged. *Ornithidium* Salisb. has a rigidly attached, unhinged labellum, and thus we feel it should be recognized, even though many authors do not do so. As a member of the subtribe Maxillarinae, all *Maxillaria* species have four dorsiventrally flattened pollinia in two unequal pairs, more or less well-developed, usually semilunate viscidium, and variously sized and shaped stipites or no stipe at all.

In Venezuela there have been recorded about 75 species of *Maxillaria*, of which 47 are known in the Venezuelan Guayana. All major groups within the genus are represented in southern Venezuela. In terms of numbers of species, *Maxillaria* is only surpassed in the Venezuelan Guayana by *Pleurothallis* R. Br. (ca. 57 species) and *Epidendrum* L. (ca. 51 species). The next-largest genus is *Octomeria* R. Br. (ca. 29 species).

A survey of *Maxillaria* species, associated with the Orchidaceae treatment for Steyermark's *Flora of the Venezuelan Guayana* (Carnevali et al., in

[1] We are grateful to Lic. Bruno Manara for the drawings and criticisms of the Latin diagnoses and to Dr. Julian Steyermark for permitting us to use drawings originally intended for publication in his *Flora of the Venezuelan Guayana*. We also thank Drs. Gustavo Romero, Ernesto Foldats, Gilberto Morillo, and Angel Carnevali for their suggestions and critical reading of the manuscript. We are indebted to Mr. Darko Elakovich for his drawings of *M. santanae*. For crucial access to the orchid collection of the Herbario Nacional de Venezuela (VEN) we thank the staff of the herbarium, especially its curators Dr. Gilberto Morillo and Lic. Libia Laskowski.

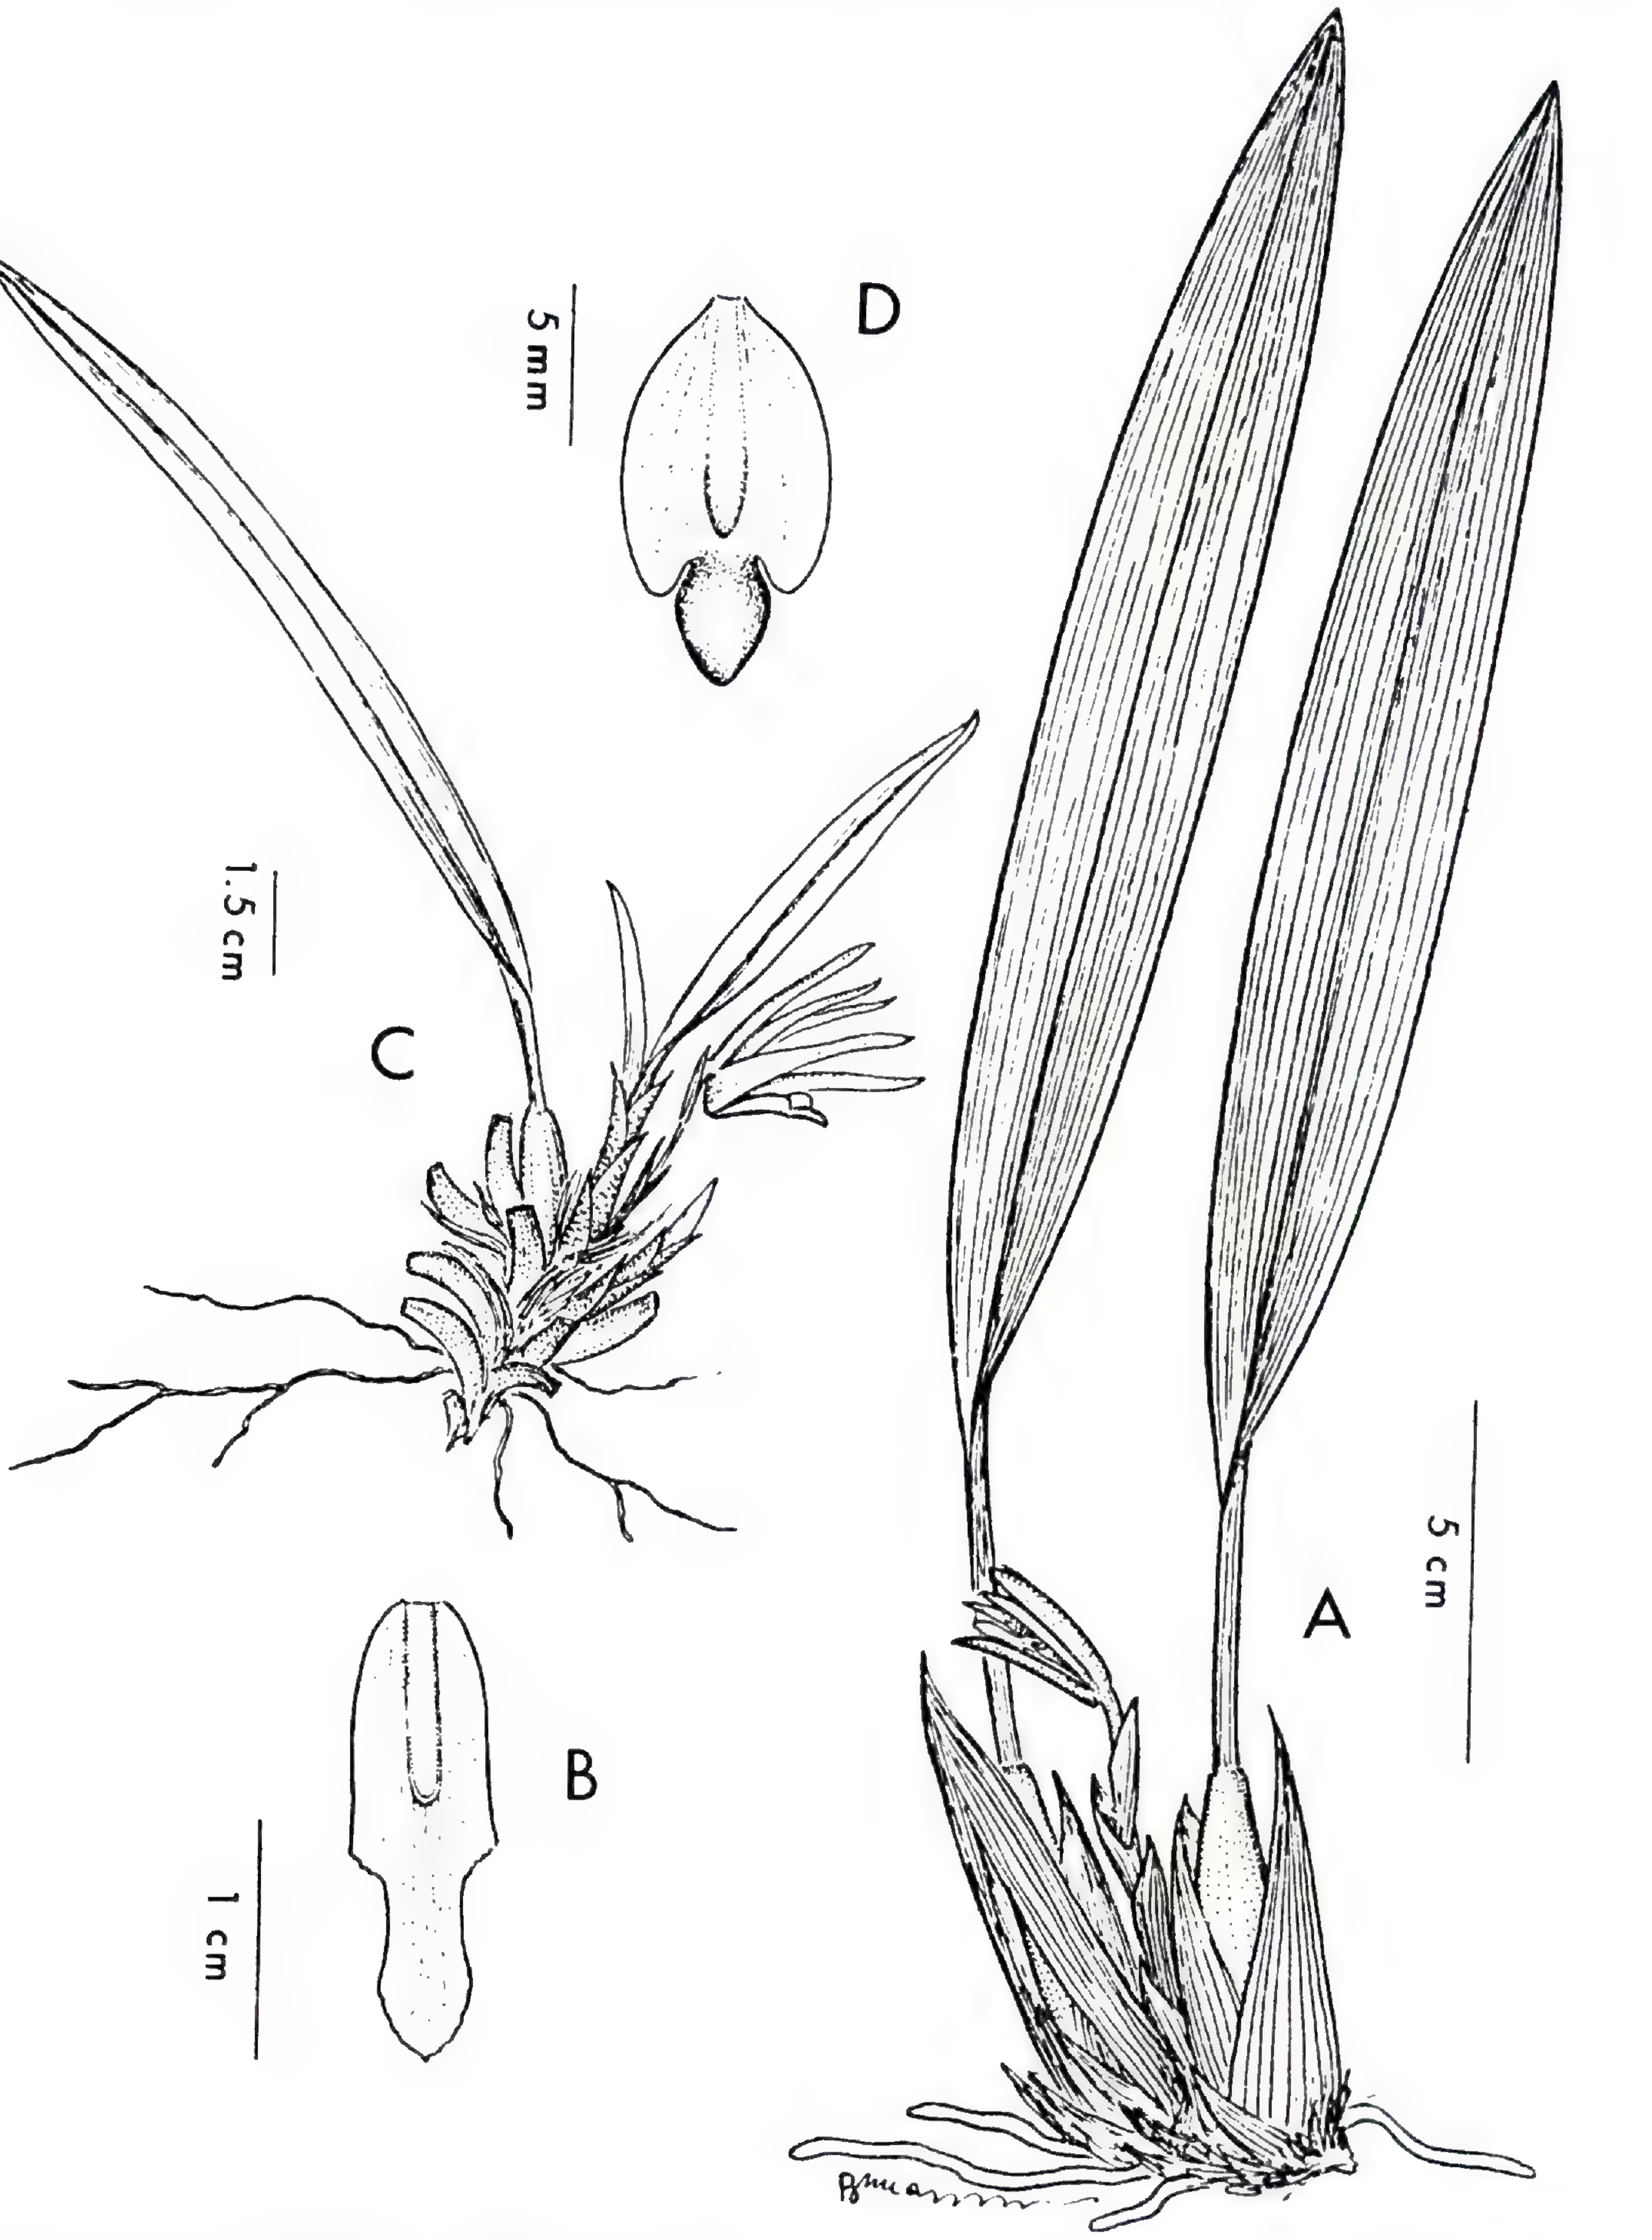

FIGURE 1. A, B. *Maxillaria foldatsiana*.—A. Flowering habit.—B. Labellum, flattened.—C, D. *Maxillaria tenuis*.—C. Flowering habit.—D. Labellum, flattened.

prep.) has revealed: 1) a new subspecies of *M. auyantepuiensis* Fold. and a new species closely related to it, 2) an undescribed taxon in the *Dicrypta* group of the genus, and 3) a new record for the Venezuelan flora, *M. tenuis* C. Schweinf.

THE *MAXILLARIA AUYANTEPUIENSIS* COMPLEX

Our studies of the complex of taxa centered around *M. auyantepuiensis* Fold., which includes *M. desvauxiana* Reichb. f., *M. neophylla* Reichb.

f., and a few others, have revealed a previously undescribed species and a new infraspecific taxon referable to *M. auyantepuiensis*. Here we provide the descriptions of both new taxa.

Maxillaria foldatsiana Carnevali et I. Ramírez, sp. nov. TYPE: Venezuela. Bolívar: Uaipantepui, 1,200 m, *T. Koyama & G. Agostini 7378* (holotype, VEN). Figure 1A, B.

Species haec *M. auyantepuiensi* affinis, sed differt: labello triplo longiore quam latiore (duplo longiore quam latiore in *M. auyantepuiensi*) et lobulo medio conspicue unguiculato (subsessili in *M. auyantepuiensi*).

Apparently epiphytic, erect herbs, 27–30 cm high. Rhizome abbreviated with aggregated pseudobulbs. Pseudobulbs narrowly ovoid, 4.7–5 cm long, 1.3–1.6 cm wide at their broadest, monophyllous, concealed by appressed, scarious sheaths. Leaves coriaceous, erect, narrowly elliptic, acute, basally attenuate into a subcylindric pseudopetiole 4–4.5 cm long, leaf total length 23–24.5 cm, the blade 18.5–20 cm long, 2.3–2.6 cm wide. Inflorescences originating from the pseudobulb base, flowers solitary; peduncle subterete, entirely concealed by 4–5 tubulose, scarious sheaths, 3–5 cm long. Flowers medium-sized for the genus, apparently vertically erect. Perianth segments scarcely open. Floral bracts elliptic, acute, 1.4–1.5 cm long, 0.4–0.5 cm wide. Pedicellate ovary apparently subcylindric, 15–17 mm long. Dorsal sepal narrowly oblong-elliptic, acute, 20–20.5 mm long, 4–4.5 mm wide. Lateral sepals narrowly triangular, acute, 20–21 mm long, basally 3.5–4 mm wide. Petals narrowly elliptic, slightly obovate, acute or narrowly obtuse, 19 mm long, 4–4.5 mm wide. Labellum parallel to the column, in general outline narrowly oblong, 17–18 mm long, 4.5 mm wide at its broadest, slightly pandurate-trilobate above the middle; central lobe elliptic, obtuse-rounded, slightly concave, 7 mm long, 2.5 mm wide, basally attenuate in a short unguiculus about 2 mm long and wide, the narrowly oblong longitudinal callus apically rounded and centrally concave, 7 mm long, 0.8 mm wide. Column straight or slightly recurvate, hemicylindric, ventrally concave, 8 mm long and 2 mm wide at the thickened apical zone. Clinandrium apiculate.

This species is very similar to *M. auyantepuiensis*, from which it differs in its inflorescences longer than the pseudobulb (vs. subequal or shorter), narrowly elliptic floral bracts (vs. widely elliptic), petals to 4.5 mm wide (vs. at least 6 mm in *M. auyantepuiensis*), and conspicuously narrower labellum (in *M. auyantepuiensis* it is approximately twice as long as wide vs. more than three times longer than wide in *M. foldatsiana*). Further, the labellum of *M. foldatsiana* is less trilobulate. As *M. foldatsiana* is only known from the type collection, and the differences between the two species are not deep, we feel that more material may show *M. foldatsiana* to be only a variation of *M. auyantepuiensis*. However, we have studied many specimens of *M. auyantepuiensis* (alive and dried) and have never noticed intergradation in the differential characters, so we think that they are best treated as closely related but distinct species.

This apparently scarce species has been collected only once despite repeated collecting trips to the summits of the tepuis in the last ten years. Perhaps it is endemic to Uaipantepui.

We take great pleasure in naming this species after our friend and colleague Dr. Ernesto Foldats, orchidologist. He was the first to notice the new species as undescribed.

Maxillaria auyantepuiensis is very common in the Gran Sabana, in southeastern Bolívar, Venezuela. Surprisingly, it is seldom collected. This species comprises two infraspecific taxa, one of which has remained undescribed.

Maxillaria auyantepuiensis subsp. *auyantepuiensis* is terrestrial or lithophytic, always growing on sandy soils or on acid sandstone, forming large colonies in more or less open places as scrub or savannalike tepui formations. It is usually exposed to full sun or resides under the light shade of shrubs. Occasionally it reaches the gallery forest margin or even its interior, provided there is enough light and is always over sandstone outcrops or sandy soil. Morphologically, *M. auyantepuiensis* subsp. *auyantepuiensis* is highly variable with fusiform to (rarely) spherical pseudobulbs and sessile to long-petiolate leaves. The sheaths that conceal the pseudobulb do not defibrate but remain intact. The inflorescences vary from shorter than to longer than the pseudobulb and are always conspicuously peduncled. The flowers are held in an upright or suberect posture. The perianth segments are relatively long and narrow with petals 18–19 mm long, 4.3–4.5 mm wide (width/length = 0.38–0.42) the dorsal sepal is 20–21 mm long and 3.5 mm wide (width/length = 0.16–0.17).

Maxillaria auyantepuiensis Fold. subsp. **epiphytica** Carnevali & I. Ramírez, subsp. nov. TYPE: Venezuela. Bolívar: bosque húmedo en las vacinidades del km 119 al sur de El Dorado, 130 m, 12 Jan 1964, *J. A. Steyermark*,

TABLE 1. Characters distinguishing subspecies of *M. auyantepuiensis*.

Characters	Subspecies	
	auyantepuiensis	*epiphytica*
Substrates	Sandy soil or sandstone outcrops	Epiphyte on trees
Habitats	Various tepuilike associations	Rain and cloud forest
Pseudobulb sheaths	Intact	Defibrating
Pseudobulb shapes	Spherical to ellipsoid	Spherical
Leaves	Sessile to long-petiolate	Always long-petiolate
Flowers	Erect to suberect	Spreading horizontally
Petals length × width	18–19 × 4.5 mm	15–16 × 5 mm
Width/length	0.42–0.45	0.30–0.38
Dorsal sepal length × width	20–21 × 3.5 mm	16–17 × 4.5–5 mm
Width/length	0.16–0.17	0.27–0.31

G. C. K. & E. Dunsterville 92993 (holotype, VEN).

Subsp. haec subsp. *auyantepuiensi* vaginis dissolutis, tepalis proportione latioribus differt itemque habitu epiphytico et in silvis pluvialibus incola.

The subspecies are distinguished in Table 1. Both subspecies have been illustrated in Dunsterville & Garay (1965: 181, 498). Plants A, C, and D there depict the variation to be expected in *M. auyantepuiensis* subsp. *auyantepuiensis*. Plant B represents our new *M. auyantepuiensis* subsp. *epiphytica*.

The new subspecies comprises populations of epiphytic plants from rain or cloud forest at variable altitudes from 600 to 1,400 m, with spherical or broadly ellipsoid pseudobulbs that are small in proportion to leaf length and are concealed by defibrating sheaths. These pseudobulbs occur on a short to long, obviously creeping rhizome, which adheres to the bark of the host tree. The leaves are always long-petiolate and very elongate with respect to pseudobulb length. The almost-epedunculate inflorescenses are always shorter than the pseudobulbs, and the flowers are almost held horizontally. The flowers are of proportionately smaller dimensions than in subsp. *auyantepuiensis*, with relatively broader perianth segments (dorsal sepal 16–17 mm long, 4.5–5 mm wide (width/length 0.27–0.31). The labellum is almost identical in the two subspecies.

Maxillaria auyantepuiensis subsp. *epiphytica* is superficially similar to the Ecuadorian species *M. neophylla* Reichb. f., but this has an acute central labellum lobe. The new subspecies also suggests a vegetatively reduced *M. desvauxiana* Reichb. f. from the Amazonian Basin, but their labella are very different, and *M. desvauxiana* does not have defibrating sheaths concealing the pseudobulbs.

The new subspecies has a wider distribution than the typical subspecies and extends beyond the Guayana boundaries. We know of a population in Guatopo, Estado Miranda, of the Coastal Range, represented by *Patrszeck s.n.*, 13 Feb. 1963 (VEN), also a population from Barinitas, Estado Barinas, in the Andean foothills, from which we have living material but no voucher.

The typical subspecies appears to be restricted to the acid sandy soils of the Roraima Formation, and this may explain a limited range in geographic terms even though it appears to be locally abundant in its natural habit.

Paratypes. VENEZUELA. BOLÍVAR: Selva húmeda con árboles de un promedio de 25–30 m de altura en el drenaje del Río Cuyuní, km 140–141.5 al sur de El Dorado, 1,300–1,380 m, 22–28 Dec. 1970, *J. A Steyermark, G. C. K. & E. Dunsterville 104324* (VEN); Cerro Guaiquinima, Río Szczrbanari (Río Carapo), 750 m, 20–25 Jan. 1977, *J. A. Steyermark, G. C. K. & E. Dunsterville 113219* (VEN). MIRANDA: Guatopo, 13 Feb. 1963, *Patcrzck s.n.* (VEN) (Colección en líquido *Dunsterville 252*).

Study of the *Dicrypta* group of the Venezuelan Guayana has revealed an apparently undescribed taxon:

Maxillaria santanae Carnevali & I. Ramírez, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Departamento Atabapo, Cerro Marahuaca, porción central. Bosque con árboles hasta 20 m, aprox. 1,000 m. Floración en cultivo en el orquideario del colector, 11 Nov. 1986, *G. Santana 1* (holotype, VEN). Figure 2.

Species haec *M. crassifoliae* et *M. superfluae* affinis sed species nostra habito conspicue parviore, petalis et labello proportione latioribus et labello unicalloso cinnabarino vel cinnabarino-roseo lobo centrali late triangulari discrepat.

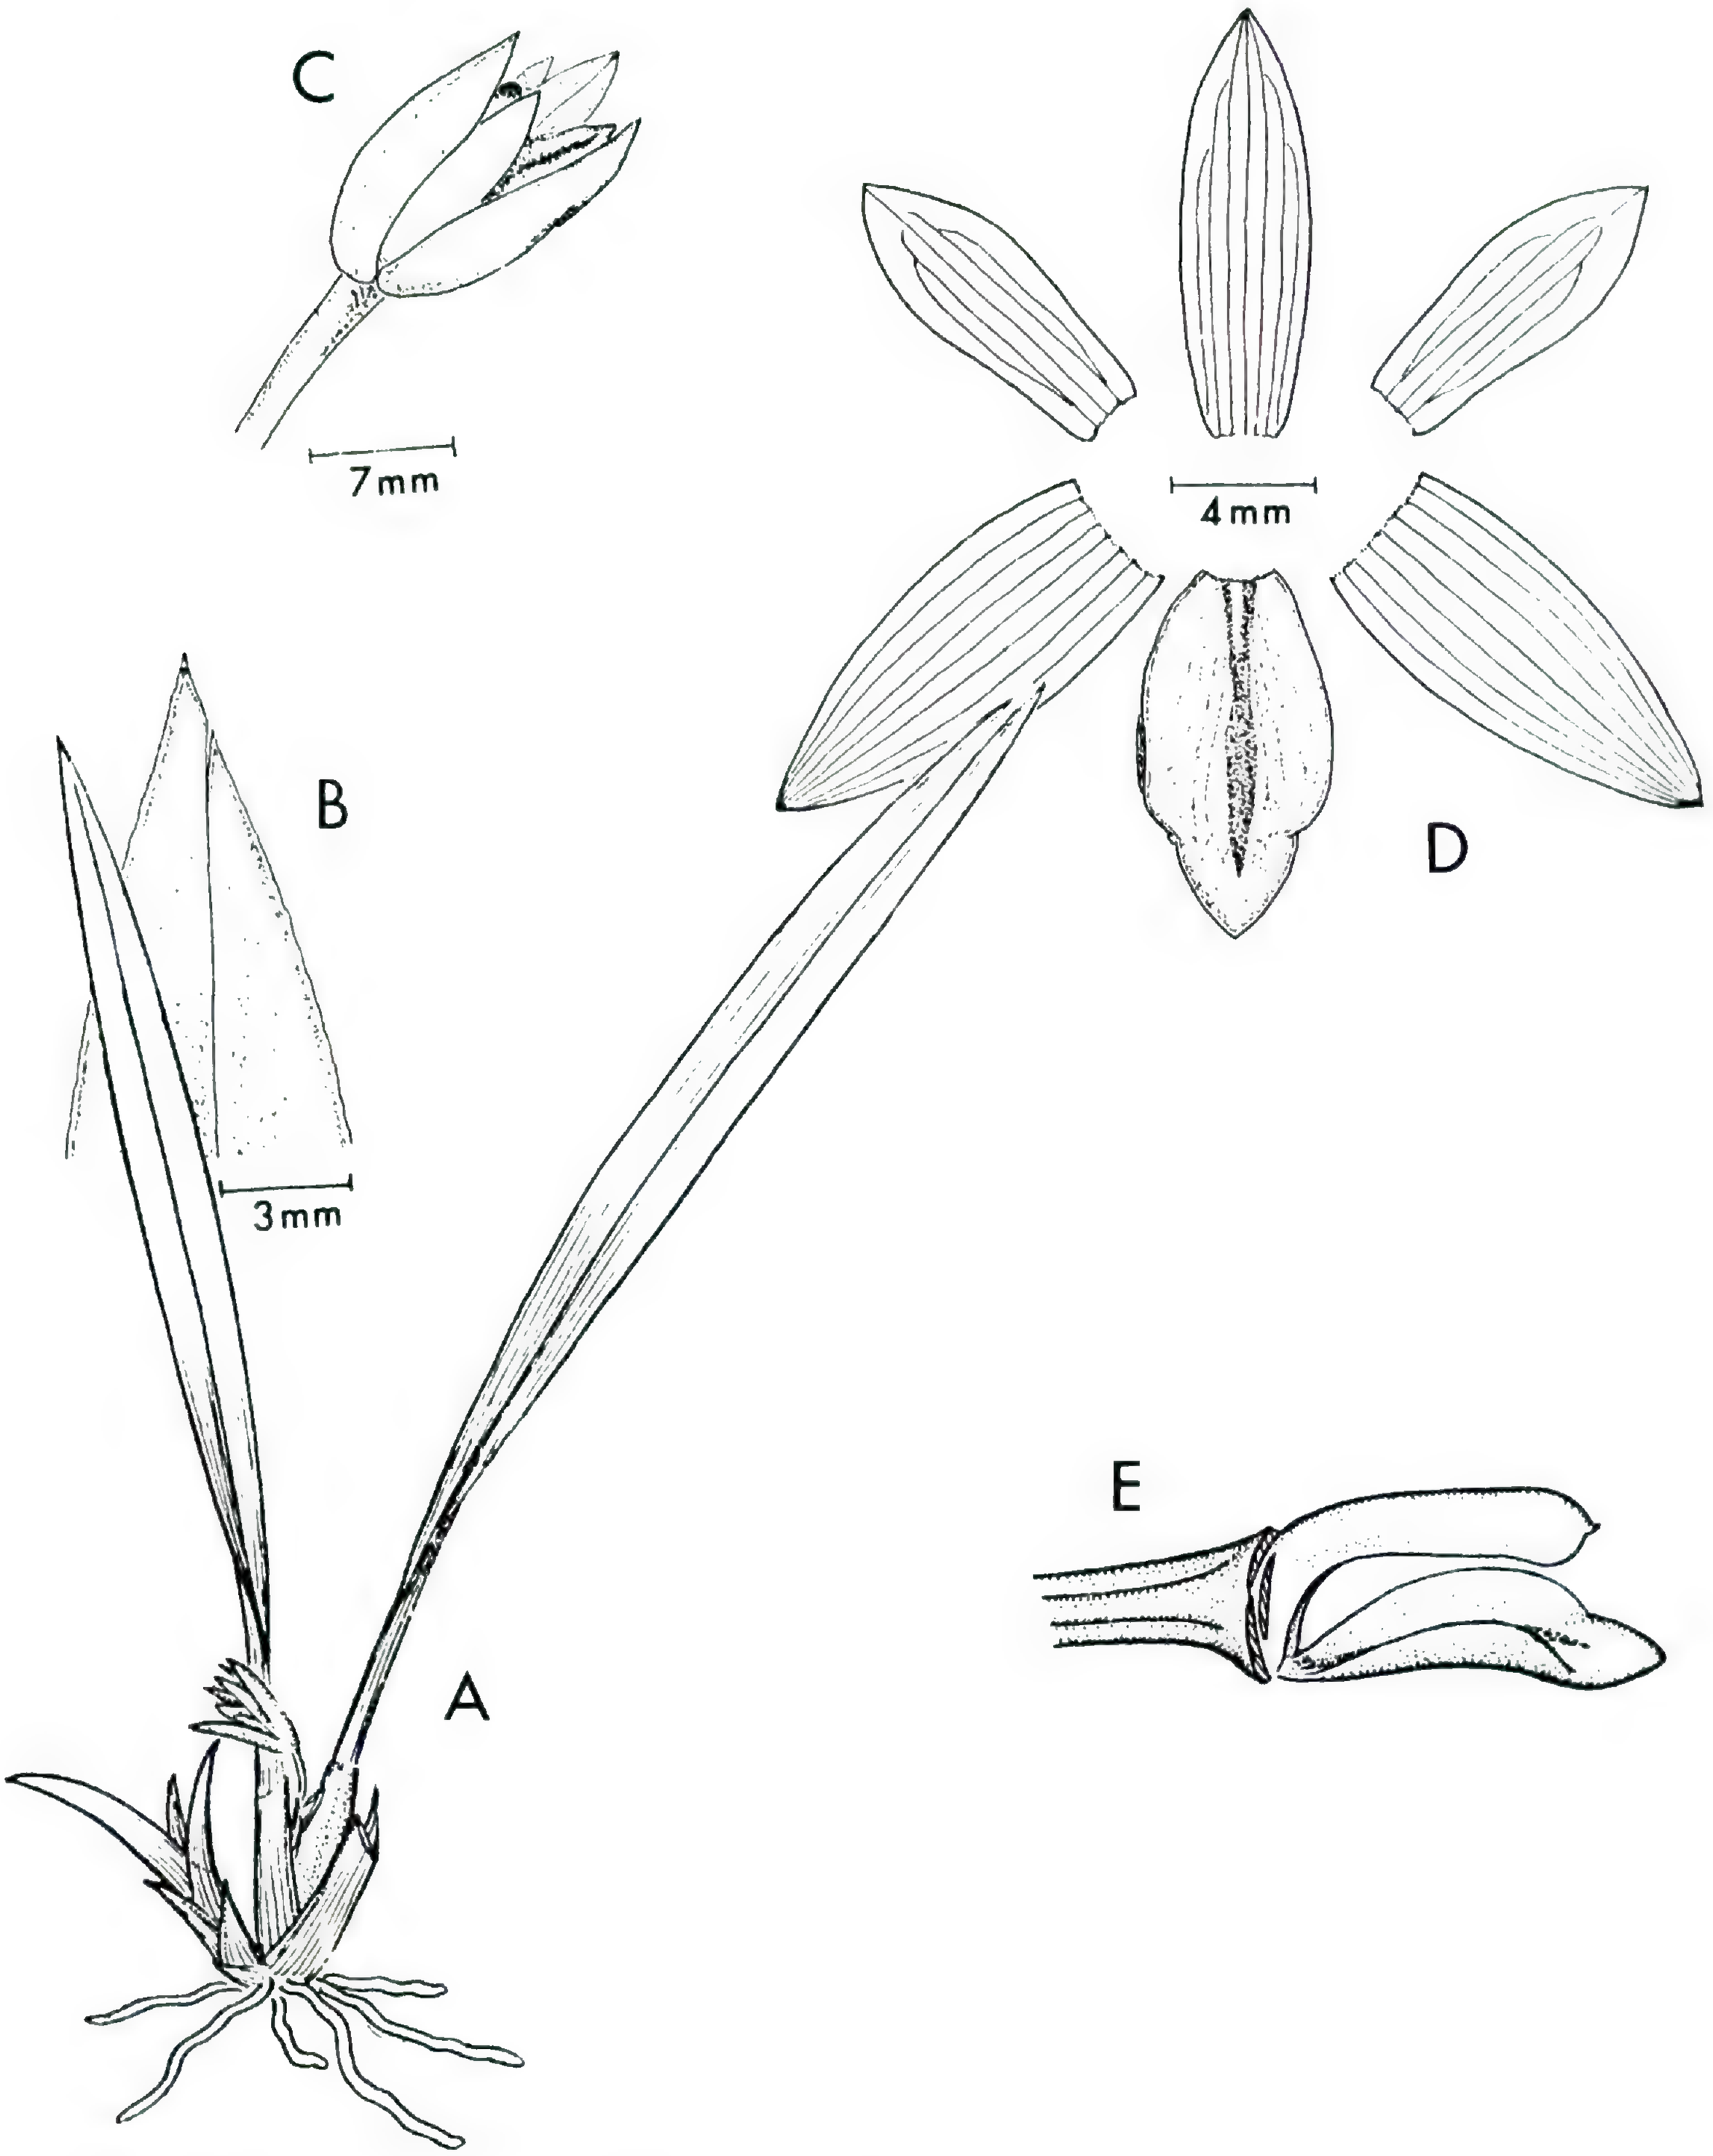

FIGURE 2. *Maxillaria santanae*. —A. Flowering habit. —B. Foliar apex. —C. Lateral view of flower at anthesis. —D. Perianth segments, flattened. —E. Labellum and column.

Small to medium-sized, epiphytic, caespitose, erect herbs, 11–23 cm high. Rhizome short and proportionately thick, entirely concealed by scarious sheaths. Roots proportionately thick and long, pale brown. Pseudobulbs aggregate, ovoid-ellipsoid, ancipital, 2.1–3 cm long, 0.6–1 cm wide, apically unifoliate, clothed with 4–5 sheaths, the innermost 2–4 of these with foliar blades, the blades falling after 2–3 years of growth, leaving the sheaths persisting and becoming grayish brown in fresh or

dry condition. Leaves fleshy-coriaceous, erect or patent-erect, the outer leaves 10–15 cm long from the articulation, the apical leaf 14–21 cm long, 7–10 mm wide when fresh, 5–9 mm wide when dry, basally attenuate and forming a pseudopetiole 1–2.3 cm long, the blade apex acute and deeply oblicuous-bilobulate (one of the halves of the blades 2–4 mm longer than the other). Inflorescences one-flowered, originating from the leaf-sheath axils one at a time. Peduncle subterete, fleshy, 17 mm long, concealed by 3–5 subimbricate, distichous sheaths. Floral bract similar to the peduncle bracts, narrowly triangular, acute, membranose, 6 mm long, 2.5–3 mm wide. Pedicellate ovary subterete, 9–10 mm long, 2.5 mm thick. Flowers medium-sized, campanulate, erect or suberect; perianth segments fleshy, subparallel to the column, greenish yellow, the petals with or without a few small brown-orange dots, the labellum pale orange or rose-lilac with orange-brown basal patches and a salmon-colored, tomentose callus. Sepals elliptic-oblong, acute; the laterals slightly oblicuous, 11–13 mm long, 4–5 mm wide, with a dorsally thickened apex. Petals narrowly obovate-elliptic to narrowly elliptic, subfalcate, acute, 10–10.5 mm long, 2.7–3.2 mm wide. Labellum basally articulate with the column-foot, in overall shape elliptic, subtrilobate about the apical fourth, 9–9.5 mm long, 5–5.5 mm wide between the margins of the lateral lobes; lateral lobes suberect and making a concave labellar disc; central lobe broadly ovate or broadly triangular obtuse, 3.8–4 mm long, 2.8–3.2 mm wide, fleshier than the rest of the labellum and with a central concavity originating where the callus ends, the disc with a thickened, waxy, tomentous longitudinal callus, this 6–7 mm long, 1 mm wide. Column semiterete, slightly thickened, apically arcuate, 6.5–7 mm long; column foot 2–3 mm long. Anther subconic, 2 mm long, obtuse, the basal margins erose.

Paratypes. VENEZUELA. BOLÍVAR: confluencia del Caño Makarupai con el Río Akaruai, unos 10–15 km al SO de la Misión de Wonken, ca. 850 m, en bosque macrotermico medio/medio, caracterizado por una gran abundancia de epífitas debido a los rápidos de la confluencia. Floración en cultivo, Maracay, 2 Jan. 1984, *G. Carnevali 1445* (VEN).

This relatively scarce species has a wide range within the Venezuelan Guayana. One of the authors collected living plants of it in 1982 in the surroundings of Peray-tepui (W of Sta. Elena de Uairén, Gran Sabana, Estado Bolívar), but no voucher was made. The affinities of *M. santanae* lie with all the species of the *Dicrypta* group: M. *crassifolia* Reichb. f.; *M. superflua* Reichb. f., and perhaps *M. bicallosa* (Reichb. f.) Garay, *M. chartacifolia* Ames, and others. This is a difficult group in need of revision—the characters distinguishing the component members are not well defined and seem unreliable. Among the *Dicrypta* group, *M. santanae* can be easily recognized by its small vegetative stature; very narrow leaves; broadly ovate or broadly triangular, obtuse central labellum lobe; and orange-yellow or rose-lilac labellum, which has a callus in the disc and lacks another in the central lobe as is usual in other species of the group.

We are pleased to name this species after Dr. Gustavo Santana, an enthusiastic orchid collector and knowledgeable amateur orchid grower. He collected the living plant from which the holotype specimen was prepared and kindly provided fresh vegetative and floral material for study.

Maxillaria tenuis C. Schweinf., Bot. Mus. Leafl. 11: 289, T. 18, fig. 1, c–d. 1945. TYPE: Perú. Loreto: Mishuyaco, near Iquitos, 100 m, in forest, *Klug 1045* (holotype, US). Figure 1C, D.

Small to medium-sized epiphytic herbs. Rhizome abbreviated. Pseudobulbs cylindric, ellipsoid or oblongoid, apically unifoliate, 1.5–2.3 cm long when mature, 5–7 mm wide, concealed by oblong-ovate, acute, and acuminate sheaths, these verruculous-pustulose without, the innermost bearing leaf blades. Leaves coriaceous, 11–14 cm long, 6–8 mm wide, the blades linear, acute, the base attenuate into a short pseudopetiole 3–15 mm long. Inflorescences erect, 1-flowered, solitary, originating from the base of the young pseudobulbs. Peduncle subterete, 1.5–3.2 cm long, concealed by 2 elliptic, acute, acuminate sheaths, these verruculose without, 8–11 mm long, slightly longer than internodes. Floral bracts almost identical to the last peduncle bract, 9–11 mm long, about 6 mm wide. Pedicellate ovary subterete, longitudinally sulcate, verruculose, 11–12 mm long. Flowers medium-sized but large for the plant, with white tepals and a yellow and white labellum having purple nerves. Perianth segments subcoriaceous, parallel to the column. Dorsal sepal very narrowly elliptic, acute and acuminate, concave basally, 18–27 mm long, 3–4 mm wide. Lateral sepals narrowly oblong to linear-lanceolate, acuminate, slightly oblicuous, 18–27 mm long, 4 mm wide basally, decurrent on the column-foot and forming with it a short mentum. Petals linear-lanceolate, acuminate, 16–23 mm long, 2–2.3 mm wide. Labellum fleshier than the other perianth segments, broadly elliptic to elliptic-ovate overall, trilobate near the apical third, 9.5–10 mm long

between the apices of the extended lateral lobes, 5–6 mm wide; lateral lobes erect and narrow, ending in a free ovate-rounded portion about 1 mm long with the apical margins minutely erose; central lobe very fleshy, 3.5–4 mm long, 2.5–3 mm wide, triangular ovate, acute or obtusate, minutely apiculate subapically, the ventral face rugulous-papillose and longitudinally sulcate. Disc along its entire length with an oblongoid callus, 5–6 mm long, with an apically rounded surface. Column proportionately short, about 4.5 mm long, semiterete, basally produced into foot about 2 mm long.

Additional specimen examined. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: surroundings of San Carlos de Río Negro, on the road to Solano, 100–120 m, Dec. 1986, *H. L. Clark 8098* (VEN).

Distribution. Known from the rain forests between 80 and 200 m in the Amazonian Basin of Peru, Brazil, and Venezuela.

This is the first record of this species for Venezuela. Since the Venezuelan material shows a few differences with the other known populations, here we offer a complete description with the full range of variation. *Maxillaria tenuis* seems to be rather variable. The type material from Iquitos, Amazonian Peru (*Klug 1045*, US), has sepals about three times longer than labellum (27 : 9.5 mm) and a triangular-ovate central labellar lobe. The second collection known, collected in Amazonian Brazil (*G. A. Black 48-2676*, IAN; *G. A. Black 48-2747*, IAN), has a very narrow central lobe (half the width of the type material) and an apparently bilobated labellar callus. Based on this Brazilian material, a var. *amazonica* Pabst was described (Pabst, 1955). All persons experienced with *Maxillaria* herbarium material know how difficult it is to rehydrate and reconstruct labella in these species, especially the central lobe and calluses, so we wonder if the narrower central lobe and bilobated callus are not artifacts. Provided they are not, we would think that var. *amazonica* could stand as a good variety or subspecies, even though in Pabst & Dungs (1975) they seem to have rejected Pabst's variety without explanation. The third population of the species to be sampled is the one we report here, which seems to depart from the type and from Brazilian material in having shorter sepals, less than two times longer than labellum (18 : 10 mm). The labellum is identical with that of the type material. By orchid standards this seems to be a good difference for the recognition of at least a subspecies, but we feel that the evidence is too scanty, as is the known material, and further material could bridge the gap between the three known populations of this extremely variable species.

Maxillaria tenuis is a well-marked species, especially its vegetative morphology: oblongoid, elongate pseudobulbs, linear leaves, and verrucose-pustulose sheaths. San Carlos de Río Negro is only a hundred meters away from Colombia, across the Río Negro, so we would expect to find *M. tenuis* also in Colombia.

CONTRIBUCION AL GENERO *MIMOSA* (MIMOSACEAE)[1]

Renée H. Fortunato[2]

Abstract

A taxonomic revision of four species of the genus *Mimosa* L. from Austroamerica is presented. *Mimosa pauperioides* (Burk.) Fortun., stat. nov. is proposed as a species, and its affinity and taxonomic position are discussed. Synonyms of *M. balansae* M. Mich. and *M. niederleinii* Burk. are given. *Mimosa petraea* Chodat et Hassl. is restricted to the Paraguayan territory. All these taxa are briefly described and their geographic distributions are given.

Como parte de la revisión que se esta realizando del geńero *Mimosa* L. para la Argentina, Bolivia, Paraguay, y Uruguay, se da a conocer el estudio taxonómico de cuatro especies presentes en el área. Estas especies pertenecen a la sección *Mimosa* (Bentham, 1842, 1875) por presentar flores haplostémonas.

Dentro de dicha sección, según ciertos caracteres exomorfológicos (hábito, presencia de acúleos, número de pinnas, número de folíolos) se agruparía a *M. pauperioides* y *M. balansae* en la serie *Pectinatae* Benth. y a *M. niederleinii* y *M. petraea* en la serie *Pedunculosae* Benth.

En el sistema de clasificación de Bentham, la ubicación taxonómica de muchas de las especies de *Mimosa* en cada serie es dudosa. A través del estudio biosistemático que se esta efectuando en el género para Austroamerica se espera poder seleccionar los caracteres de valor taxonómico.

1. Mimosa pauperiodes (Burk.) Fortun., stat. nov. *M. balansae* M. Mich. var. *pauperioides* Burk., Darwiniana 8: 146, fig. 22. 1948. TIPO: Argentina. Corrientes: 4 Dec. 1941, *Birabén 5027* (holotipo, LP). Iconografía: A. Burkart in N. Troncoso & N. Bacigalupo, Col. Ci. INTA 6(3): 503, fig. 224, e–i. 1987.

Sufrútice prostrado; tallos estrigosos, delgados, aculeados, a veces inermes; acúleos 1–2 de 0.5–3 mm long., infraestipulares o internodales (generalmente ramas aculeadas e inermes en la misma planta). Pinna uniyugada de 1.5–5 cm long.; folíolos 4–18-yugados de 2–9 mm long. × 0.6–2 mm lat., angostamente elípticos, asimetricos en la base, pubescencia combinada de pelos estrigosos y sedosos en ambas caras, a veces solo estrigosos en la cara abaxial. Inflorescencia con pedúnculos 1–2 por axila de hasta 11 cm long., mayores que las hojas. Flores rosadas; cáliz hialino; corola de 2.5–3 mm long., glabra, 4-lobulada, lóbulos pubérulos en el ápice. Craspedio subtoruloso, hispido y pubérulo en replo y artejos.

Distribución. Común en los suelos arenosos del estado de Rio Grande do Sul en Brasil y en las provincias argentinas de Entre Rios y Corrientes.

Mimosa balansae var. *pauperioides* fue diferenciada (Burkart, 1948) de *M. balansae* var.

[1] Se agradece a la Lic. Maria Mercedes Arbo por la lectura crítica del manuscrito y a la Fundación Robert Bass por la beca otorgada para consultar la importante colección depositada en el Field Museum of Natural History, Chicago, Illinois, U.S.A. Asimismo, se hace extensivo el agradecimiento a los curadores de los herbarios aquí citados, por el préstamo de los ejemplares.

[2] Departmento de Botánica Agrícola, INTA, Castelar 1712, Prov. de Buenos Aires, Argentina. Investigadora del Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET).

balansae por presentar folíolos más angostos y el nervio medio prominente. En el material estudiado se observó que además de los caracteres citados por Burkart, también se podía diferenciar a *M. balansae* var. *balansae* por poseer inflorescencias mayores que las hojas, y tallos inermes o con 1–2 acúleos internodales y/o infraestipulares. Todas estas diferencias se mantienen constantes, e inclusive son más importantes que las existentes entre *M. balansae* y otras especies afines. Por lo aquí descrito, se propone considerar a *M. pauperioides* como especie independiente de *M. balansae*.

En los ejemplares inermes es facil confundir a *M. pauperioides* con *M. petraea*. Ambas presentan afinidad en el tipo de hábito y número y forma de los folíolos; no obstante se diferencian por el largo del pedúnculo, pubescencia, y tamaño de los folíolos.

Según Bentham (1842, 1875), la serie *Pectinatae* Benth. se caracteriza por agrupar sufrútices pequeños o raro arbustos, generalmente con acúleos infraestipulares o internodales, pinna uniyugada, folíolos multiyugados (a veces hasta 6–8-yugados), pedúnculos 1(2) axilares o formando racimos compuestos apicales (desarrollo posterior de las hojas), racimos globosos, flores 4-meras, y craspedio setoso a hispido. A su vez, la serie *Pedunculosae* Benth. se diferencia de *Pectinatae* casi únicamente por incluir especies inermes. En el estudio de ambos grupos supraespecificos, se ha observado que la presencia de acúleos es un caracter variable en muchas especies del género, como ocurre con *M. pauperioides*. Este taxon solo presenta algunas ramas con uno o dos acúleos pequeños, y a veces es una planta totalmente inerme. Si se siguiera el criterio de Bentham, erróneamente se consideraría a los ejemplares aculeados en la serie *Pectinatae* y a los inermes en *Pedunculosae*. Por otro lado, esta especie es más afín a *M. petraea* de la serie *Pedunculosae*. Como se ha señalado, en su mayoría, los caracteres diferenciales descriptos por Bentham para las series del género *Mimosa* no responden a un patrón estable.

2. Mimosa balansae M. Mich., Mém. Soc. Phys. Nat. Genève 28(7): 52, fig. 18. 1883. TIPO: Paraguay: Trinidad, Mar. 1875, *Balansa 1479* (lectotipo, G, selecionado aquí; isolectotipo, F); *Balansa 1479a* (sintipo, G, fragmento F; fotografía n° serie F (ex B†)—1397, F, G, SI); Villa Concepción, in pratis, *Balansa 1835* (sintipo n.v.). Iconografía: A. Burkart in N. Troncoso & N. Bacigalupo, Col. Ci. INTA 6(3): 501, fig. 224, a–d. 1987.

Mimosa balansae M. Mich. var. *robusta* Chodat et Hassl., Bull. Herb. Boissier ser. II. 4: 488. 1904. TIPO: Paraguay: in campis San Bernardino, Nov. 1898/99, *Hassler 3507* (holotipo, G; isotipo, F).

Mimosa balansae M. Mich. var. *rojasiana* Hassl., Repert. Spec. Nov. 8: 557. 1910. TIPO: Paraguay. Gran Chaco: ad ripam occidentalem flum, lat. S23°20′, 23°30′, Oct.? 1903, *Hassler 2355* (holotipo, G).

Sufrútice de ± 15–80 cm alt., erecto a prostrado, robusto a ± grácil; tallos con pubescencia pubérula y estrigosa, ± patente, esparcida a densa, raro glabros; acúleos 2–5 mm long., rectos a recurvos, infraestipulares, presentes en ternos o variando su número de 1–6 (a veces 1 o 2(3) internodales), raro sin acúleos. Pinnas uniyugadas; folíolos (3–)8–25-yugados, 5–15 mm long. × 2–4.5 mm lat., elípticos a angostamente elípticos, estrigosos y pubérulos en ambás caras, hasta completamente glabros en el epifilo, nervio medio subcentral, poco visible en la cara abaxial (solo a veces en la base y/o en el ápice), borde estrigoso-pubérulo, no formando un margen nerviforme. Inflorescencia racemosa; pedúnculos 1–2 por axila, menores que las hojas. Cáliz 0.25–0.5 mm long., hialino, truncado a brevemente ciliado en el borde; corola 2–3.5 mm long., membranácea, glabra, lóbulos pubérulos en el ápice. Craspedio 1–2 cm long. × 0.4–0.5 cm lat., subtoruloso, pubescente.

Distribución. Crece preferentemente en espartillares. Su distribución se extiende desde Bolivia, Paraguay hasta Uruguay, S de Brasil y NE Argentino.

Se ha observado en el campo y en el material de herbario que *M. balansae* forma un complejo donde los caracteres descriptos (hábito, pubescencia, número de acúleos, largo de la pinna, y número y largo de folíolos) aparecen combinados en los diferentes ejemplares. Esta variabilidad imposibilita realizar una división infraespecífica natural de la especie, por ello se considera que los epítetos varietales *robusta* y *rojasiana* son solo probables formas ecológicas que presenta el complejo citado.

Mimosa balansae var. *rojasiana* fue descripta por Hassler con folíolos glabrescentes en la cara adaxial. Al estudiar el material típico se pudo observar que los folíolos son pubescentes en ambas caras.

De los tres sintipos citados por Micheli en la descripción original de *M. balansae*, se han podido estudiar *Balansa 1479* y *1479a* (G, F). En esta nota se selecciona y se propone como lectotipo a *Balansa 1479* depositado en el herbario G por ser un ejemplar más completo (fl, fr, y tres hojas de herbario) que *Balansa 1479a*.

3. Mimosa niederleinii Burk., Darwiniana 7: 523. 1947. TIPO: Argentina. Misiones: Varana, 23 Ago. 1887, *Niederlein 1107* (holotipo, SI). Iconografia: A. Burkart, Darwiniana 8: 162, fig. 26. 1948.

Mimosa niederleinii Burk. var. *riograndensis* Burk., Darwiniana 7: 526, fig. 4. TIPO: Brasil. Rio Grande do Sul: Estrela, Mar. 1899, *Dutra 382* (holotipo, HB; isotipo, SI).

Arbusto o sufrútice de ± 0.5–1.5 m alt., ascendente; tallos ramificados, estrigosos y pubérulos, inermes. Estipulas 3–5 mm long. × 0.5 mm lat., subuladas a lanceoladas; pecíolo 0.4–1.5 cm long., pubescente; estipelas 2–3 mm long. × 0.25–0.5 mm lat., subuladas a lineares; pinna uniyugada 3–5 cm long.; folíolos 18–55-yugados, 4–8 mm long. × 0.5–2 mm lat., oblongos, asimétricos en la base, papiráceos a subcoriáceos, discoloros, cara adaxial glabra, brillante, cara abaxial pubérula, levemente estrigosa o hirsuta, raro glabra a subglabra, con 1–2(–3) nervios, nervio medio central a subcentral, prominente, borde ciliado, formando un margen nerviforme (o no marginado). Inflorescencia en racimos espiciformes 1.5–3.2 cm long., axilares. Flores rosadas; bráctea 0.5–1 mm long. × 0.25 mm lat., 1-nervia; cáliz ± 1 mm long., 2-partido a ± 4-dentado, escarioso, blanquecino, lacerado en el ápice, pubérulo en la base; corola 1.5–2 mm long., 4-lobulada, con pubescencia retrorso-estrigosa. Craspedio 1–2 cm long. × 0.3–0.5 cm lat., recto a subtoruloso, 3–4-articulado, artéjos 5–7 mm long., subcuadrados, estrigoso-pubérulos.

Distribución. Vive preferentemente en campos húmedos y modificados del planalto brasileño. Es dudosa su presencia en el territorio argentino, siendo citada para la provincia de Misiones, unicamente sobre la base del ejemplar tipo.

Material selecto examinado. BRASIL. PARANÁ: Bocaiuva do Sul, campina dos Tavares, *Hatschbach 3498* (HB, MBM, SI); Piriquara, Nova Tirol, margens do corrego, 930 m, *Hatschbach 24207* (MBM); Piraquara, Mananciais da Serra, *Oliveira 791* (F); km 168, Municipio Jaguariaira, *Kummrow 438* (RB); Rio Potinga, *Kummrow 402* (LP). SANTA CATARINA: Lajes, Rio Caveiras, Estrada da Rodagem Federal, km 8 S de Lajes, *Smith et al. 11316* (SI). RIO GRANDE DO SUL: Costa do Cadeia, Triunfo, *Sobral 1648* (F); Taquara, Caracol, *Rambo 28704* (SI); Osorio, Fazenda do Ayo. prox. Osorio, *Rambo 46755* (SI); Caracol, prox. Canela, *Rambo 52807* (SI).

En 1947, Burkart describió para Rio Grande do Sul a *M. niederleinii* var. *riograndensis*; posteriormente, en 1979 la citó para el Estado de Santa Catarina. Según él, esta variedad se diferenciaba por presentar folíolos pubérulos en la cara abaxial y pinnas 24–54-yugadas, mientras que la var. *niederleinii* se caracterizaba por poseer folíolos con la cara abaxial pubérula y estrigosa y pinnas

19–32-yugadas. El material tipo consultado de *M. niederleinii* var. *riograndensis* posee la mayoría de los folíolos con pubescencia pubérula, pero, también, se pueden observar algunos pelos estrigosos mezclados, como ocurre en la variedad típica. Con respecto al número de folíolos por pinna, es conveniente señalar, que el material tipo de *M. niederleinii* es un ejemplar pobre y las pinnas no poseen completos los pares do folíolos. Por otro lado, en el material brasileño, se han observado varios ejemplares con pinnas 30–50-yugadas pero con pubescencia pubérula y estrigosa en la cara abaxial de los folíolos. Ante la variabilidad observada en los únicos caracteres diferenciales, se propone en esta nota considerar en la sinonimia de *M. niederleinii* a la var. *riograndensis*.

La cita de *M. niederleinii* para la Argentina fue realizada sobre la base del ejemplar tipo coleccionado en Varana (?), Misiones, por Niederlein en la expedición de la Comisíon Nacional de Límites. En 1948, Burkart señala que dicha localidad pertenece a la parte centro-oriental de la provincia de Misiones, en la region de Fracrán. A pesar de la especificación posterior, desde 1887 hasta el momento, no se ha encontrado nuevamente material de esta especie en la Argentina, en cambio sí es común hallar ejemplares recientemente coleccionados en el SE brasileño; existe la posibilidad que el material citado fuera coleccionado en el estado de Rio Grande do Sul y no en el territorio argentino.

Esta especie posee una variedad en el Edo. de Santa Catarina, Brasil: *M. niederleinii* var. *pseudolepidota* Burk. Esta variedad presenta tallos, pecíolos, pedúnculos, y craspedio con pubescencia densa, estrigosa o setulosa, y ramificada.

4. Mimosa petraea Chodat et Hassl., Bull. Herb. Boissier ser. II 4: 548. 1904. TIPO: Paraguay: in glareoris prox. Chololó in valle fluminis, Y-acá, Dec. 1900, *Hassler 6619* (holotipo, G; isotipo, F; fotografía n° serie F(G)—28277, MO, F, SI).

Sufrútice pequeño 10–30 cm alt., inerme; tallos con pubescencia estrigosa o estrigosa y pubérula, a veces con pequeñas glándulas caedizas. Estípulas 2.5–5 mm long. × 0.5 mm lat., lanceoladas a linear-triangulares, 3-nervias, glabras, ciliadas en el margen. Pecíolo 1–3 mm long.; pinnas uniyugadas 15–30 mm long.; estipelas 0.25–0.5 mm long., lineares, pilosas; folíolos 12–28-yugados 2–3.5(–4.5) mm long. × 0.75–1 mm lat., oblongos a triangulares, con 1–(2) nervios visibles en la cara abaxial, nervio medio subcentral, cara adaxial glabra, cara abaxial ± pubérula, a veces con algunos pelos estrigosos (pubescencia estrigosa, más abundante en los folíolos inferiores de la pinna). Inflorescencia axilar; pedúnculo 1(2) en la axila de las hojas superiores, 5–10 mm long., menores o iguales que las hojas; racimos globosos a subovoides de ± 4 mm long. × 4 mm lat. (sin filamentos); bráctea 2–3 mm long. × 0.5–0.75 mm lat., lanceolada, aquillada, mayores que las flores, glabra a pubérula en el ápice, 1-nervia, margen con glándulas caedizas y ciliado en el ⅓ apical, caediza; botón floral ovoide; cáliz de ± 0.5 mm long., membranáceo, glabro, ciliado en el borde; corola de 1.5–2 mm long., 4-lobulada, turbinada, lóbulos de 0.75–1 mm long., 1-nervios, glabros a levemente pubérulos; filamentos estaminales libres hasta la base. Craspedio 12–17 mm long. × 4–5 mm lat., levemente toruloso, comprimido, estrigoso y pubérulo, 3–4-seminado, artejos de 4–5 mm long.; replo ± 0.5 mm lat. Semilla ± 2.5 mm long. × 2.5 mm lat. (inmadura).

Distribución. Vive en lomadas con rocas aflorantes en las serranías de Paraguay central.

Material adicional examinado. PARAGUAY. CORDILLERA: Itacurubí, *Schinini 3207* (CTES, F). PARAGUARI: Piraretá-Piribeby, *Schinini 2594* (CTES, F, SI); links vom Piribebuy und sublich von Tobati: Serranía nordlich von Fal des Y-agui-guazu, *Fiebrig 840* (F, LIL).

En 1948 y 1952, Burkart citó a esta especie para la Argentina sobre la base del ejemplar: "Misiones, Bonpland, *P. Jörgensen 325*, IX-1909 (BAB 34712)". En el material estudiado solo se pudo encontrar un ejemplar de herbario que si bien posee los mismos datos citados en la exsiccata por Burkart, no coincide en la fecha de colección. En la etiqueta del material se lee XI-1909 y no IX-1909. Esta diferencia probablemente se deba a un error de impresión. Por otro lado, el ejemplar *Jörgensen 325* (BAB 34712) no pertenece a *M. petraea*, sino a una forma más pequeña y pubescente de *M. oligophylla* M. Mich. Al revisar todo el material depositado en el herbario del Depto. de Botánica Agricola, INTA, Castelar (BAB), se pudo comprobar que existen más ejemplares de *P. Jörgensen 325*, los cuales corresponden a distintos números de BAB y a diferentes especies de *Mimosa*, por ej., BAB 30213, 30214, 30224 = *M. oligophylla*; BAB 32116, 32117, 32118 = *M. paupera* Benth., etc. A pesar de la mezcla existente entre el material y el número de BAB, ninguno de los ejemplares vistos pertenece a *M. petraea*. Salvo por la cita de Burkart (1948), hasta el momento no se ha encontrado esta especie en la Argentina, por lo que se cirscunscribe su distribución geográfica al territorio paraguayo. No se descarta que en

el futuro pueda ser coleccionada en las provincias del NE.

En el material examinado de *M. petraea* (Burkart, 1948), fue citado otro ejemplar: "Paraguay, *P. Jörgensen 4450*," el cual tampoco corresponde a la variedad típica, sino a *M. petraea* var. *hirtula* Burk. Dicho ejemplar, al igual que el tipo y demás especímenes estudiados de var. *hirtula* se diferencian de var. *petraea* por ser un sufrútice erecto a procumbente en la base con pinnas 1–6.5 cm long., y generalmente inflorescencias mayores a iguales que las hojas.

Clement W. Hamilton[2]

GROUP 3. THE *GRACILIFLORA* GROUP

Shrub or sometimes small tree; young stems glabrous or sometimes ferrugineous-pubescent; stipules sheathing or not, triangular or ovate or lanceolate, *the apex often bifid or biaristate* (Fig. 2f), uniform in color, glabrous or less commonly fringed or ferrugineous-puberulent, caducous. *Leaf* blades usually elliptic, sometimes narrowly so, or oblanceolate or slightly obovate, *drying reddish or greenish gray, brown, or black*; secondary veins 3–14(–16) pairs, diverging (45°–)55°–90°(–100°), *eucamptodromous or brochidodromous*, with collector vein only in *P. jimenezii*, the axils with domatia (Fig. 4b) or not (with tufts of hair only occasionally in *P. bakeri*); tertiary veins orthogonal reticulate (sometimes percurrent in *P. marginata*). *Inflorescences* panicles of cymes or rarely (*P. bakeri* and sometimes *P. parvifolia*) of glomerules, *usually pedunculate*; *secondary axes usually in 1 pair per rank*, if more than 1 pair then size-differentiated, *often delicate* or diffuse in structure and *diverging at right angles* (Fig. 7h); bracts rarely conspicuously enlarged (to 6 mm long in *P. jimenezii*). *Corolla* tubes (1.5–)2–4(–5) mm long (Fig. 8), the lobes usually without apical extensions (sometimes with blunt protuberances in *P. graciliflora*). *Fruit* when dry usually ellipsoid to spherical (obloid in *P. philacra*); persistent calyx a beak or not evident; *seed dorsal surface with 3–5* (6–8 in *P. parvifolia*) *usually deep longitudinal furrows* (Fig. 10d), the ventral surface with 2 deep or broad longitudinal furrows (plus several irregular furrows in both surfaces in *P. philacra*; ventral surface often concave in *P. graciliflora* [Fig. 10c]).

The most commonly encountered species in the group, *Psychotria marginata* (distribution, Fig. 20), does not obviously closely resemble any other species. *Psychotria graciliflora* (Fig. 21), the other widespread species, is the centerpiece of the morphologically cohesive *P. graciliflora* complex, which includes also *P. bakeri* (Los Santos, Panama), *P. laselvensis* (Costa Rica), *P. liesneri* (eastern Panamá Province), *P. orosiana* (Costa Rica and Panama), *P. parvifolia* (Costa Rica and western Panama), and *P. philacra* (eastern Darién Province; see Fig. 22). *Psychotria jimenezii*, a Costa Rican species (Fig. 23), is unique in the group in having a collector vein, inflorescence bracts as long as 4–6 mm, and seed dorsal surface with usually only three longitudinal furrows, but it too may belong to the *P. graciliflora* complex.

Of the nine species in the group, six appear distylous. All six show between-morph asymmetry in floral part lengths: *Psychotria graciliflora*, *P. jimenezii*, *P. laselvensis*, *P. marginata*, and *P. parvifolia* have longer-exserted parts in pins than in thrums, and in *P. orosiana* pin reproductive organs are longer at both levels. The only positively derived state is seen in *P. liesneri*, which is long-homostylous. Available flowering material of *P. bakeri* and *P. philacra* is insufficient to determine their breeding systems.

17. Psychotria bakeri Dwyer, Ann. Missouri Bot. Gard. 67: 347. 1980. TYPE: Panama. Los Santos: Loma Prieta, Cerro Grande, 720–840 m, 8 June 1967 (fl), *Lewis et al. 2249* (holotype, MO; isotypes, F, GH). Figure 22.

Shrub to 1.5 m; young stems glabrous, the bark smooth; stipules sheathing, the sheath 2.5 mm long, biaristate with extensions 2–3 mm long, glabrous, caducous, leaving a red-brown ridge. *Leaves* petiolate; petioles 3–5 mm long, glabrous, flat above; blades membranous, narrow-elliptic, the apex acute, the base attenuate, (3–)4.5–7 × 1–1.6 cm, glabrous above and below, drying pale red-brown; secondary veins 6–7 pairs, diverging 45°–55°, brochidodromous, arcuate near margin, not elevated, glabrous, the axils occasionally with minute

[1] Part I: Introduction and Species 1–16 appears in the preceding issue of the *Annals of the Missouri Botanical Garden*, Volume 76: 67–111.

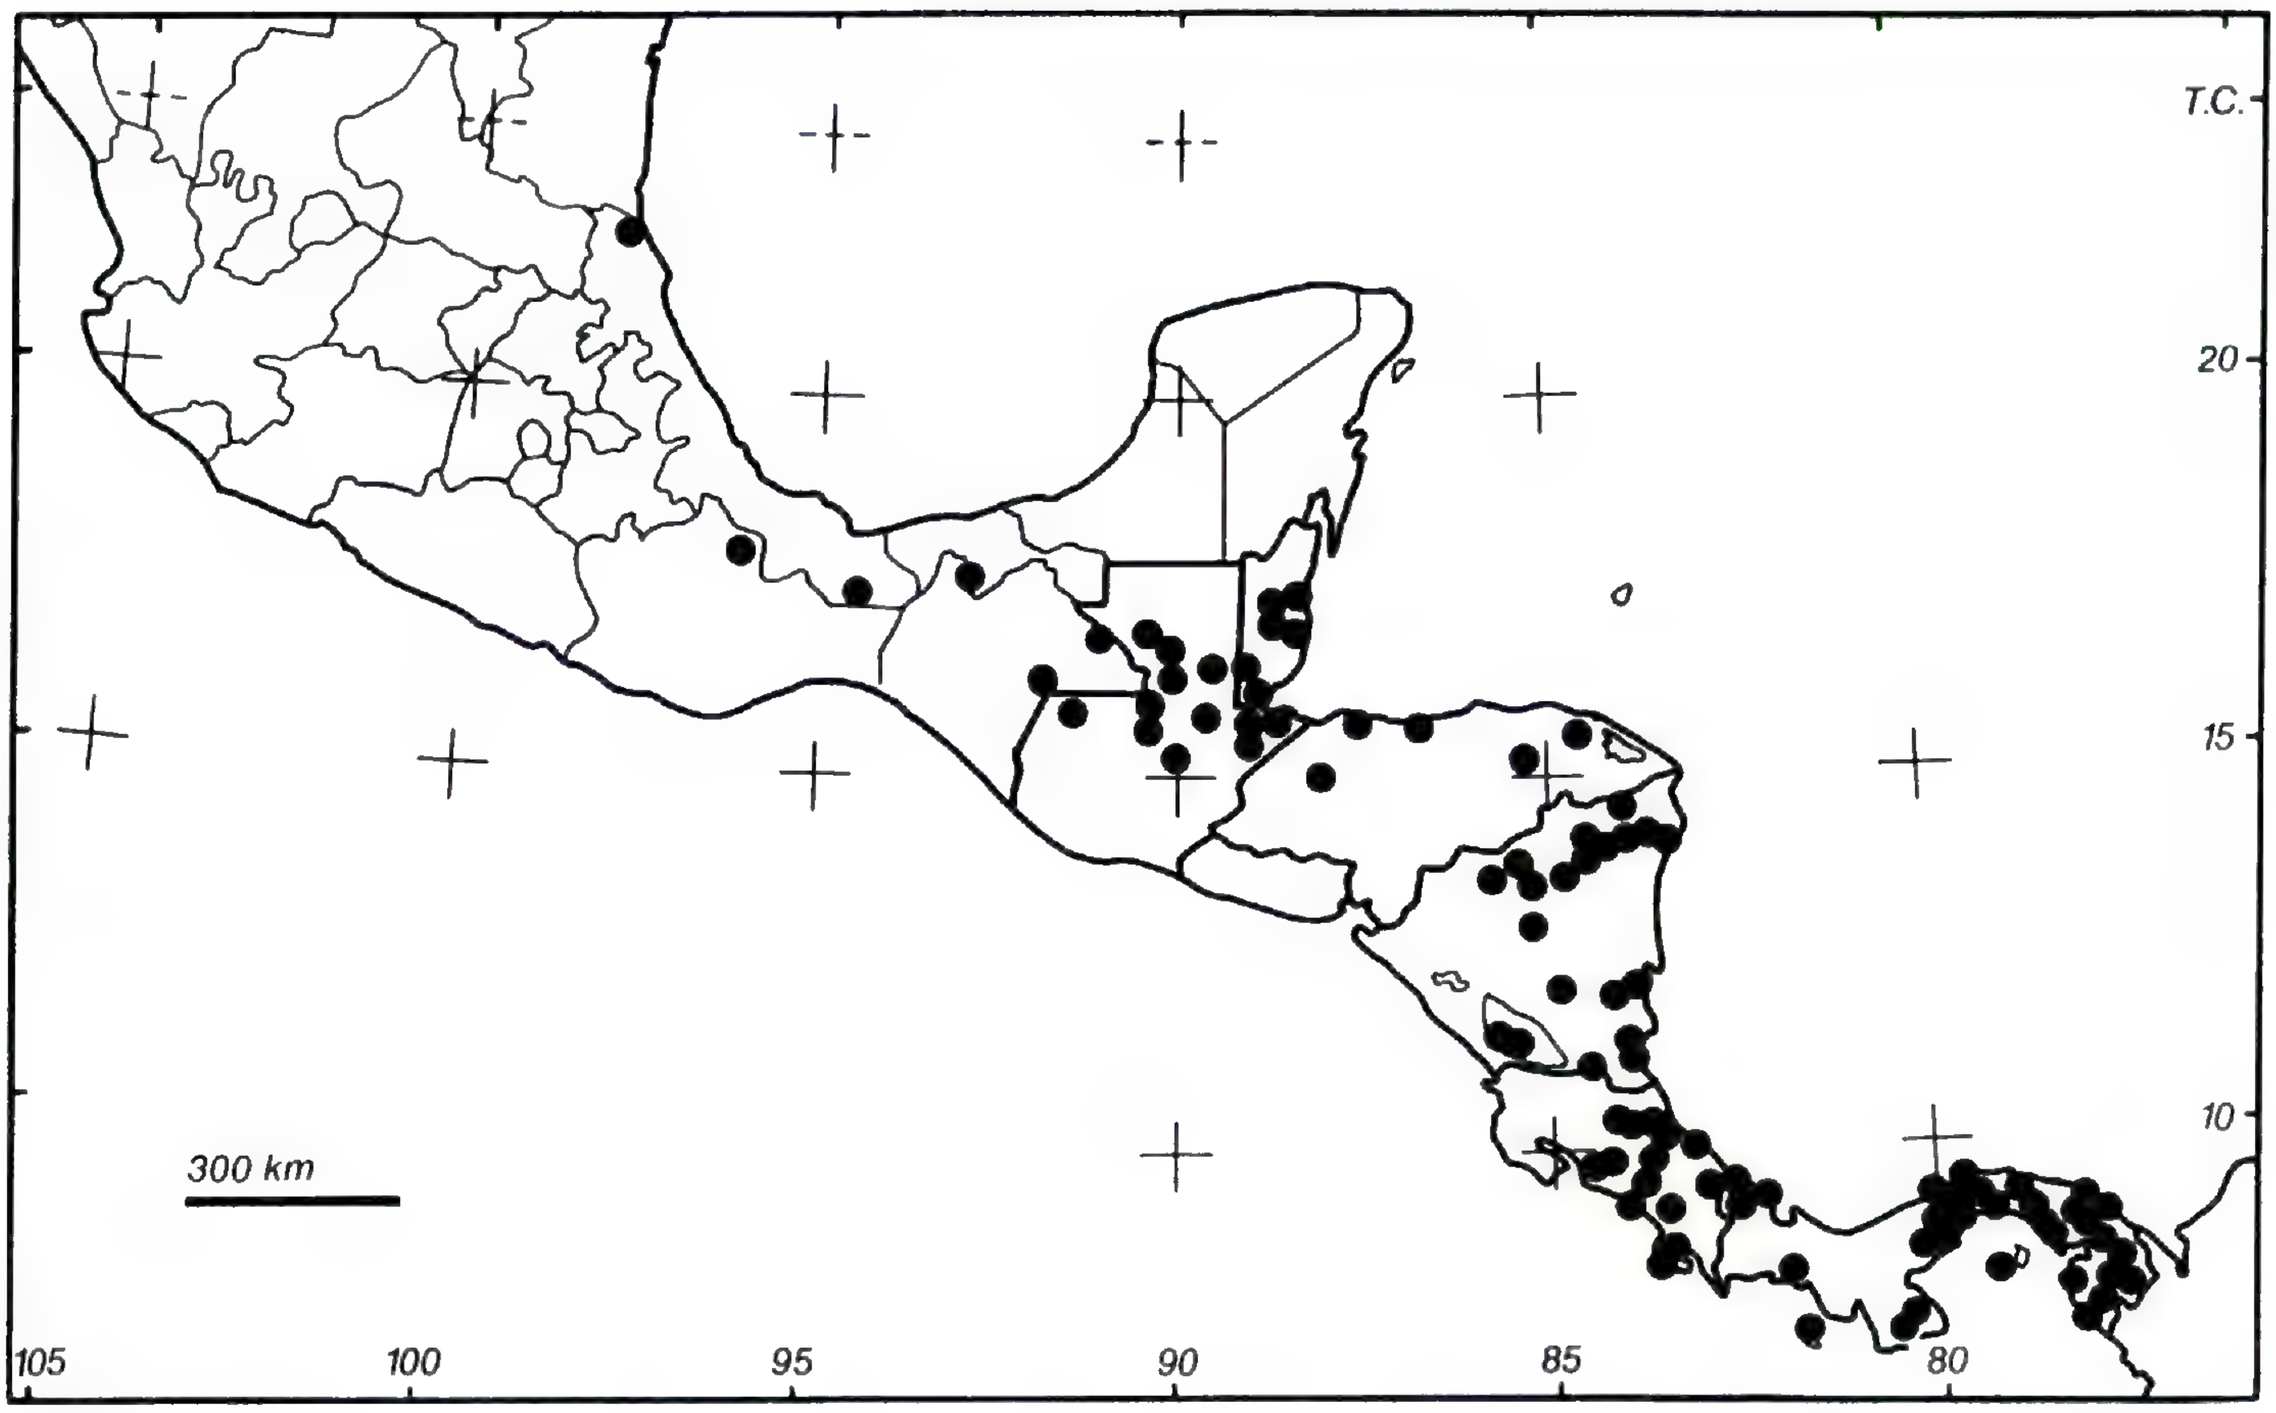

FIGURE 20. Distribution of *Psychotria marginata* in Mesoamerica.

tufts of white hairs; tertiary veins inconspicuous. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules; panicle branched to 2–3 degrees; main axis 1.5–3.5 cm long, the peduncle 1–3 cm long; secondary axes in 1 rank, the first-rank axes 2, 0.4–0.8 cm long; cymes branched to 2 degrees; bracts and bracteoles linear to triangular, often cleft, 1–2 mm long, puberulent within, the margins ciliate. *Flowers* sessile; calyx cup-shaped, the tube 1 mm long, the lobes 5, triangular, 0.5–0.7 ×

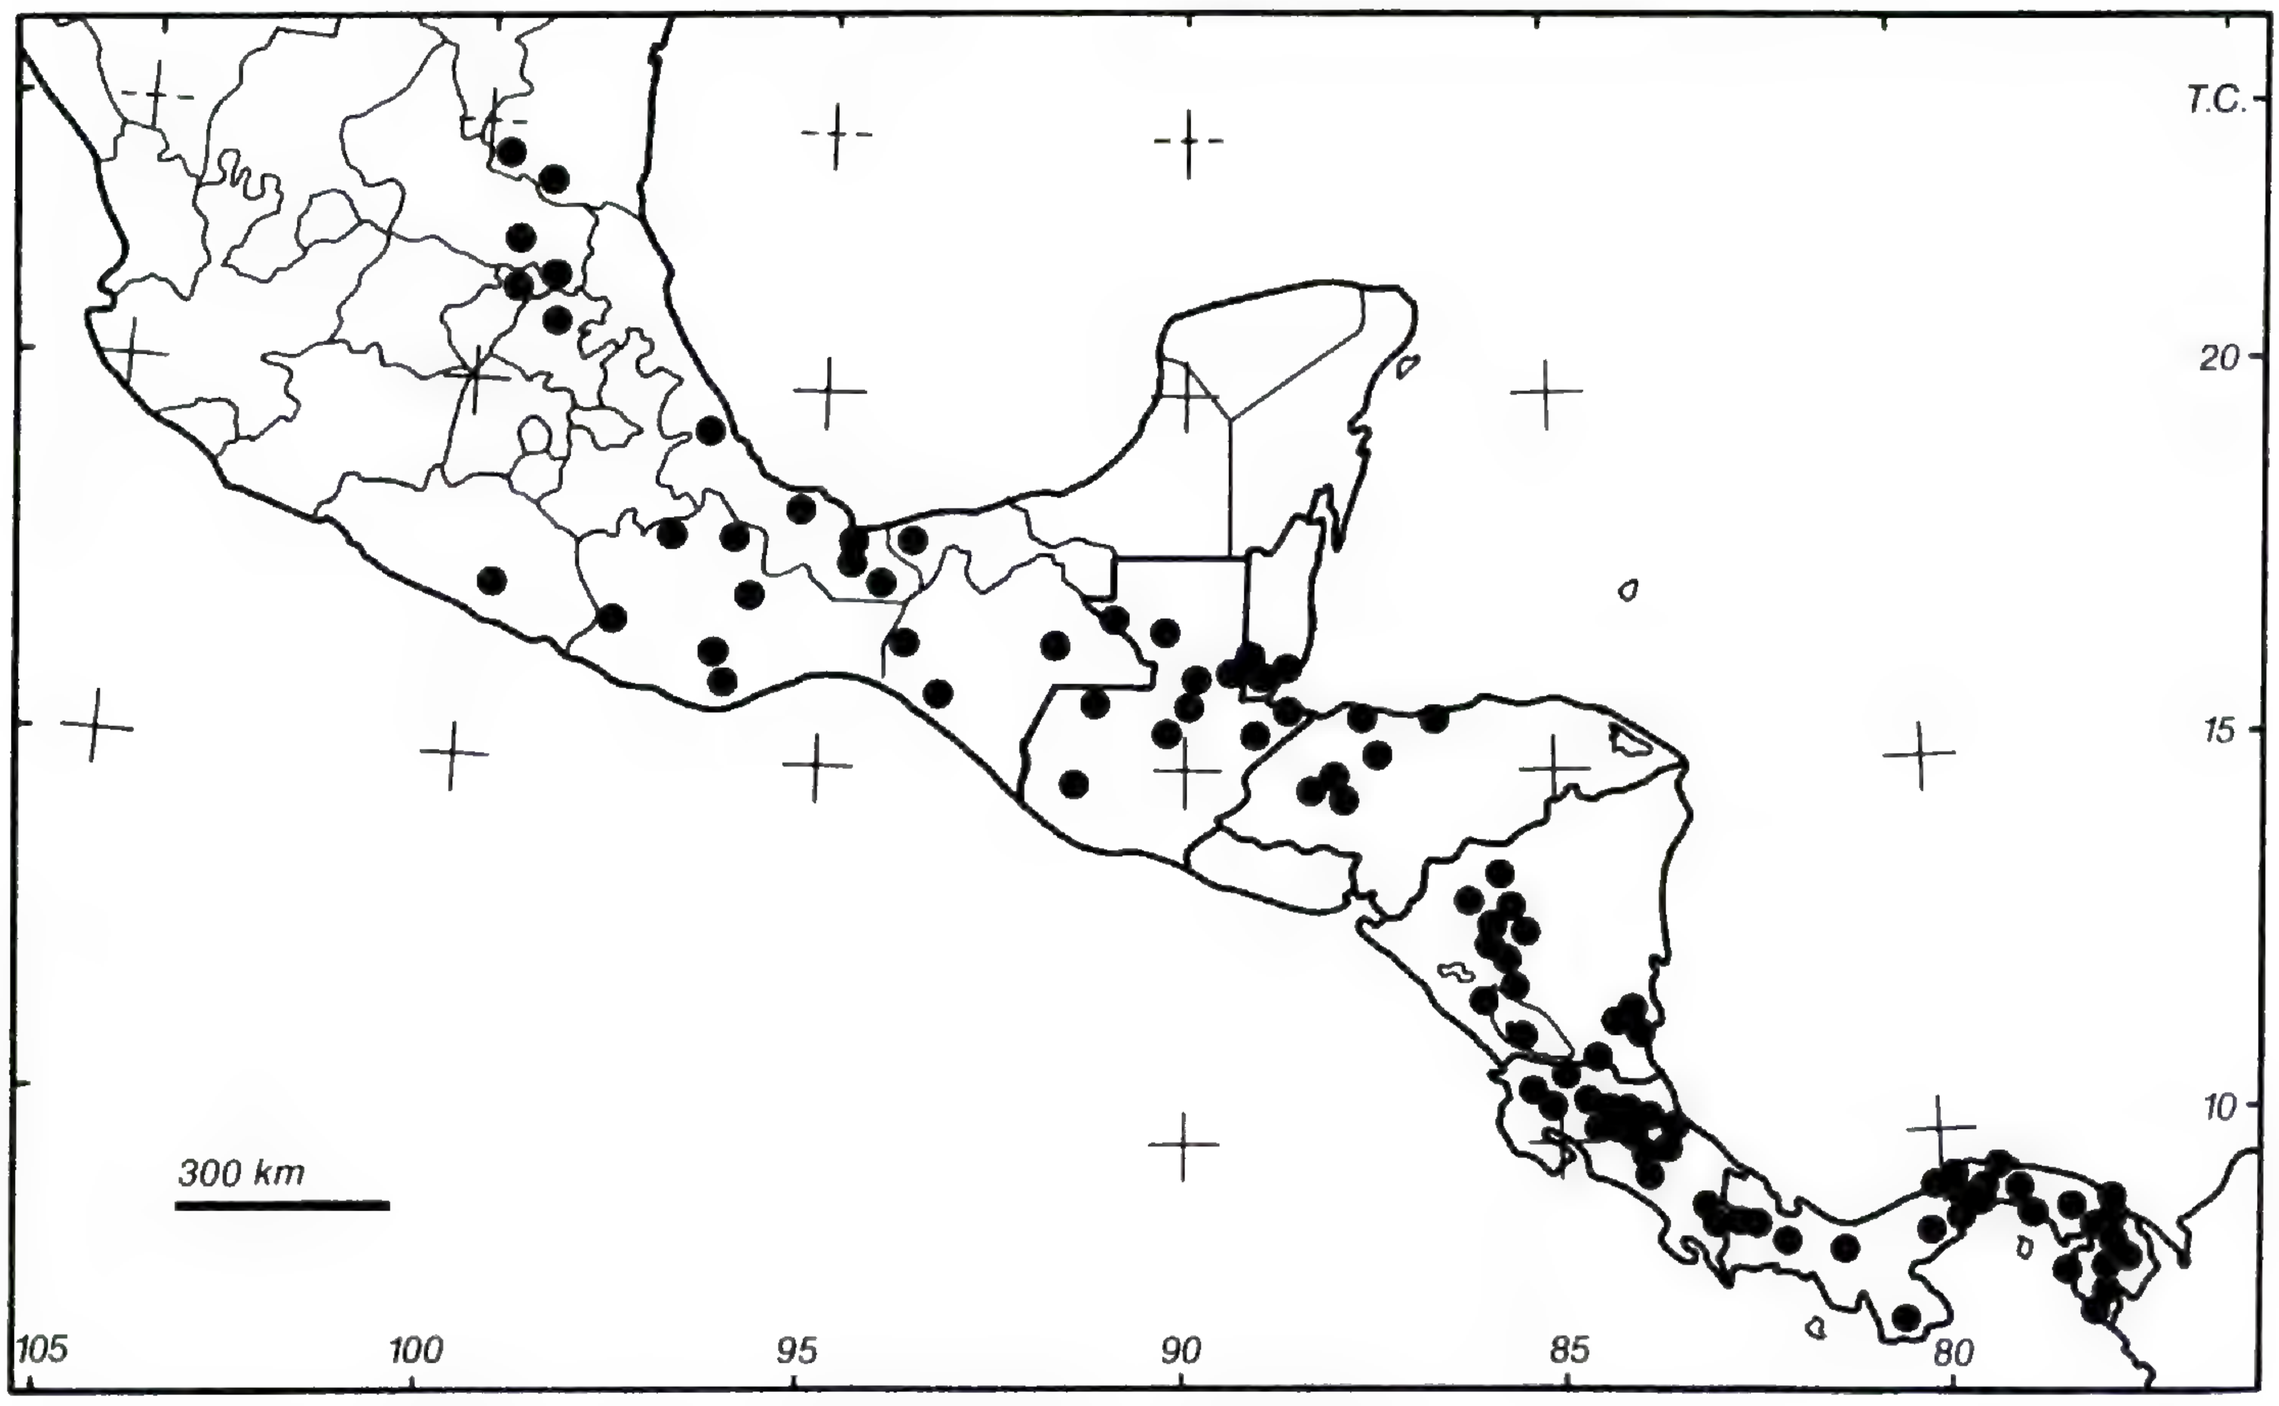

FIGURE 21. Distribution of *Psychotria graciliflora* in Mesoamerica.

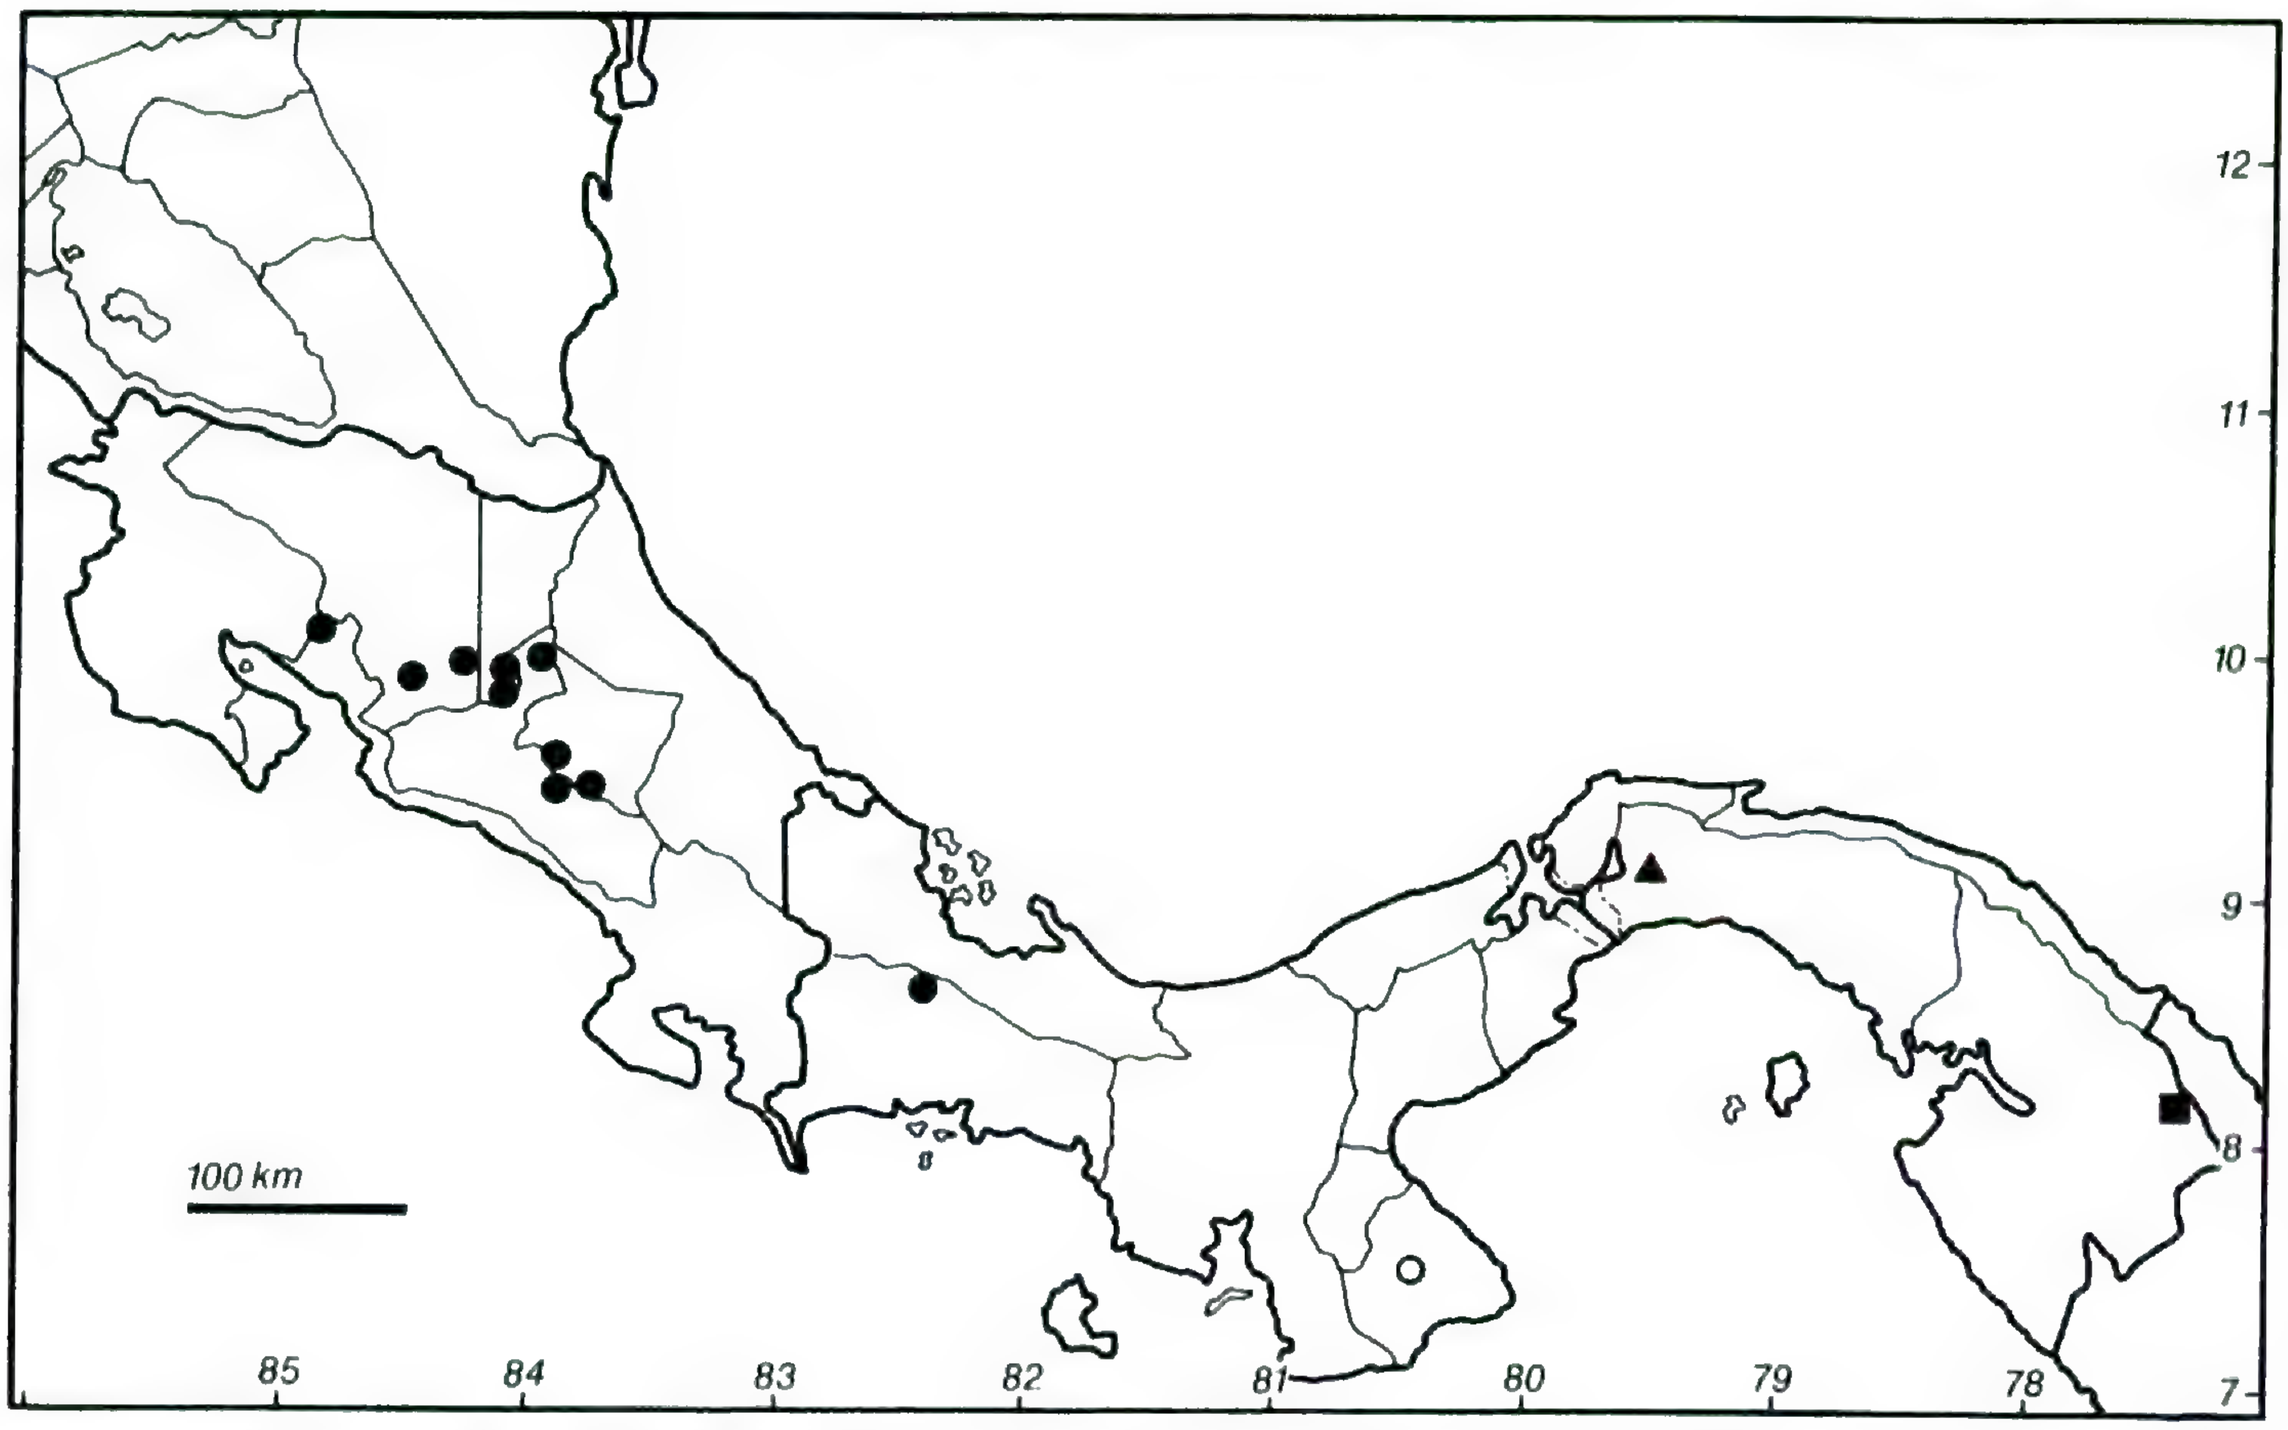

FIGURE 22. Distributions of *Psychotria bakeri* (open circle), *P. liesneri* (triangle), *P. parvifolia* (solid circles), and *P. philacra* (square).

0.6 mm, glabrous; corolla white, the tube cylindrical, 1.5–3 × 1–1.5 mm, white pubescent in throat, the lobes 5, narrow triangular, 1–2 × 1 mm; stamens 5, the filaments not seen in pins, 1.5 mm long in thrums, the anthers 1 mm long; style not seen in pins, 1 mm long in thrums, the branches linear. *Fruit* not seen.

Distribution (Fig. 22). Known only from the type collection from Los Santos, Panama at around 800 m elevation in premontane wet forest with tropical-equatorial climate. It was collected in flower on June 8.

Psychotria bakeri may be recognized by its small narrow-elliptic (usually 4.5–7 × 1–1.6 cm) leaves with acute apex and small (1.5–3.5 cm long) panicles of glomerules. Only the thrum morph has been seen, but one collection does not suffice to suggest thrum-monomorphy.

18. Psychotria graciliflora Bentham in Oersted, Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 35. 1853. *Mapouria graciliflora* (Benth.) Oerst., Amér. Centr. p. 17, t. 14., fig. 6. 1863. *Uragoga graciliflora* (Benth.) Kuntze, Revis. Gen. Pl. 2: 960. 1891. TYPE: Costa Rica. Alajuela: nr. Psychotria oaxacana Standley, Contr. U.S. Natl. Herb. 23: 1391. 1926. TYPE: Mexico. Oaxaca: nr. Sto. Domingo, 480 m, 18 June 1895 (fl), *E. W. Nelson 2688* (holotype, US).

Psychotria vallensis Dwyer, Ann. Missouri Bot. Gard. 67: 438. 1980. TYPE: Panama. Coclé: La Mesa nr. chicken farm, 3 Jan. 1974 (fl, fr), *Dwyer 11867* (lectotype designated herein, MO—2163005A; isolectotypes, F, GH, MO—2 sheets).

Shrub 1–3 m tall; young stems glabrous, the bark gray, smooth to shallowly furrowed; stipules ovate, biaristate with often puberulent extensions 3–4(–6) × 1–1.5 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* subsessile to petiolate; petioles 1–7 mm long, glabrous, flat above; blades membranous, elliptic, the apex acuminate or sometimes acute, the base attenuate to narrowly cuneate, (2–)3–8(–11.5) × (0.9–)1.3–3(–3.5) cm, glabrous above and below, drying gray-green to deep red-brown; secondary veins (4)5–8(9) pairs, diverging (67°–)70°–80°(–95°), eucamptodromous to brochidodromous, constantly arcuate, barely elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous to evident, the intersecondaries often evident, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, delicate spreading panicles of cymes; panicle branched to 3 degrees; main axis 3–5 cm long, the peduncle 2.5–3.5 cm long; secondary axes in (2–)3 ranks, the first-rank axes 2, 0.8–1.5 cm long, the second-rank axes 2, 0.2–0.6 cm

long, the third-rank axes 2, 0.1–0.2 cm long; cymes branched to 1–2 degrees; bracts triangular to linear, conspicuous, 1–3 mm long, glabrous, sometimes fringed; bracteoles irregular, 0.5–1 mm long, fringed. *Flowers* sessile to pedicellate, the pedicels to 1.5 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 5, barely evident to triangular to linear, to 1 mm long, puberulent outside; corolla white, the tube cylindrical, 2–2.5 × 1 mm, white pubescent in throat, the lobes 5, linear often with blunt protuberance near apex, 1–2 × 0.5–1 mm; stamens 5, the filaments 2–2.5 mm long in pins, 3–3.5 mm long in thrums, the anthers 1 mm long; style 4–5 mm long in pins, 2.5 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid to spherical, 4–5 mm long, 3–4 mm diam., maturing red, drying red-brown to black; persistent calyx a beak to 1 mm long; seed dorsal surface with 4 longitudinal furrows, the ventral surface concave or with 2 broad shallow longitudinal furrows (Fig. 10c).

Distribution (Fig. 21). Widespread from Mexico through Panama, missing only in El Salvador. It is noteworthy that such a common and widespread species in Central America is rare at best in South America and apparently absent from the Antilles. *Psychotria graciliflora* has the greatest elevation range of any species of the subgenus, ranging 0–2,500 m, and occurs in tropical moist to lower montane rainforest with equatorial and tropical climate. It has been collected in flower January–August, primarily March–July, and in fruit throughout the year, primarily August–February.

Types of *P. oaxacana* and *P. vallensis* have morphologies well within the normal range of *P. graciliflora* and are therefore included.

Psychotria graciliflora may be recognized by its fairly small (usually 3–8 × 1.3–3 cm) glabrous

leaves drying grayish or red-brown and with few (usually 5–8) secondary veins diverging usually 70°–80°, its small (main axis 3–5 cm long) delicate inflorescences and its small (4–5 × 3–4 mm) ellipsoid to spherical fruits often drying black. Leaves in Honduras and Nicaragua are at the upper end of the spectrum in terms of size and number of secondary veins, whereas Costa Rican specimens generally have the smallest leaves with the fewest secondaries. Calyx lobes are generally barely evident to triangular, but in Darién and eastern Panamá provinces the lobes are linear.

The exserted style in the pin morph is noticeably longer than the exserted stamens in the thrum (4–5 vs. 2.5–3 mm).

19. Psychotria jimenezii Standley, J. Wash. Acad. Sci. 15: 288. 1925. TYPE: Costa Rica. San José: La Hondura, ca. 1,400 m, 16 Mar. 1924 (fl), *Standley 37892* (holotype, US). Figure 23.

Psychotria wendlandiana Oersted ex Standley, J. Wash. Acad. Sci. 18: 9. 1928. TYPE: Costa Rica. San Miguel, 13 May 1857 (fl), *Wendland 781* (holotype, C, n.v., fragment, F, photo, F. neg. no. 22857; isotype, US).

Treelet or shrub, 2–5(–7) m tall; young stems ferrugineous-pubescent, the bark smooth; stipules lanceolate to ovate, shortly bifid, 6–9 × 3–5 mm, glabrous, often ciliate, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.3–2(–3.2) cm long, puberulent, terete; blades membranous, elliptic, the apex acuminate, the base attenuate to cuneate to cordate, (7–)8–15 × (2–)2.5–5(–5.5) cm, glabrous above, puberulent on midvein below, drying red-brown, paler below; secondary veins (11–)12–14(–16) pairs, diverging (60°–)75°–100°, brochidodromous with collector vein undulating near margin, constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous to evident, orthogonal reticulate, the intersecondaries often evident. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 4 degrees; main axis 6–7.5 cm long, the peduncle rarely lacking or 2.5–5 cm long; secondary axes in 3(–4) ranks, the first-rank axes (2)4(6), the longest pair 1.5–2.5(–4), the medium pair when present 0.5–1.6 cm long, the shortest pair when present reduced to 0.3 cm long, the second-rank axes 2 or 4, the longer pair 0.6–2.2 cm long, the shorter pair when present 0.2–1 cm long, the third-rank axes 2 or 4, the longer pair 0.4–0.8 cm long, the shorter pair when present 0.2–0.6 cm long; cymes branched to 2 degrees; bracts lanceolate, 4–6 mm long, ciliate; bracteoles triangular, often split, to 1 mm long. *Flowers* subsessile, the pedicels to 0.5 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular, barely evident to 0.2 mm long, glabrous, often ciliate; corolla cream, the tube cylindrical, 2–2.5 × 1.2 mm, white pubescent in throat, the lobes 5, lanceolate to ovate, 1–1.2 × 0.7 mm; stamens 5, the filaments 2 mm long in pins, 3 mm long in thrums, the anthers 0.7 mm long; style 3.5–4 mm long in pins, 2 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid to spherical, 3.5–5(–6) mm long, 3.5–4.5 mm diam., maturing red, drying red-brown, sometimes sparsely puberulent; persistent calyx a beak 0.3–0.5 mm long; seed dorsal surface with 3(–4) deep longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 23). Found in an east–west band across northern Costa Rica from eastern Guanacaste to Cartago and western Limón, at elevations of 200–1,600 m, mostly above 1,000 m, in tropical wet to premontane rainforest with equatorial-mountainous climate. It has been collected in flower February–May and in fruit August–March.

Selected specimens examined. COSTA RICA. ALAJUELA: nr. Qda. Guillermina, N side Volcán Arenal, 10°29′N, 84°42′W, 500 m, 21 Apr. 1973 (fl), *Lent et al. 3412* (DUKE, F, NY); Guadalupe de Zarcero, 1,625 m, 30 May 1938 (fl), *A. Smith 699* (F—2 sheets, GH, MO, NY); Villa Quesada, 600 m, 15 May 1939 (fl, fr), *A. Smith 1793* (MO, NY, US); 2 km N of Bijagua, rd. to San Miguel, 2 Feb. 1976 (fr), *J. Utley & K. Utley 2923* (CR, DUKE). GUANACASTE: 30 km E of Pan-American Hwy. on rd. to Upala, 180 m, 25 Aug. 1980 (fr), *Kress et al. 9594* (DUKE); Los Ayotes, Tilarán, 600–700 m, 21 Jan. 1926 (fr), *Standley & Valerio 45411* (F, US). LIMÓN: below La Palma, upper Río La Hondura on trail to Guapiles, 10°03′N, 83°58′W, 1,100–1,200 m, 16 Dec. 1966 (fr), *Burger 3909* (CR—2 sheets, F—2 sheets, NY). PUNTARENAS: Monteverde, 1,500 m, 14 Apr. 1981 (fl), *Haber 447* (MO). SAN JOSÉ: above Río Hondura at Baja La Hondura, 1,150 m, 31 Dec. 1974 (fr), *J. Taylor 17883* (NY, US); San Rafael nr. Heredia, 1,118 m, 13 Feb. 1890 (fl), *Tonduz 1974* (US).

Psychotria jimenezii may be recognized by its ferrugineous-pubescent aspect, elliptic leaves often with cordate bases, secondary veins usually 12–14 diverging 75°–100° with undulating collector vein, and inflorescences with secondary axes usually in two unequal pairs per rank in usually three ranks.

The exserted pistil in the pin morph is longer than the exserted stamens in the thrum morph (3.5–4 vs. ca. 3.3 mm).

20. Psychotria laselvensis C. Hamilton, Phytologia 64: 228. 1988. TYPE: Costa Rica. He-

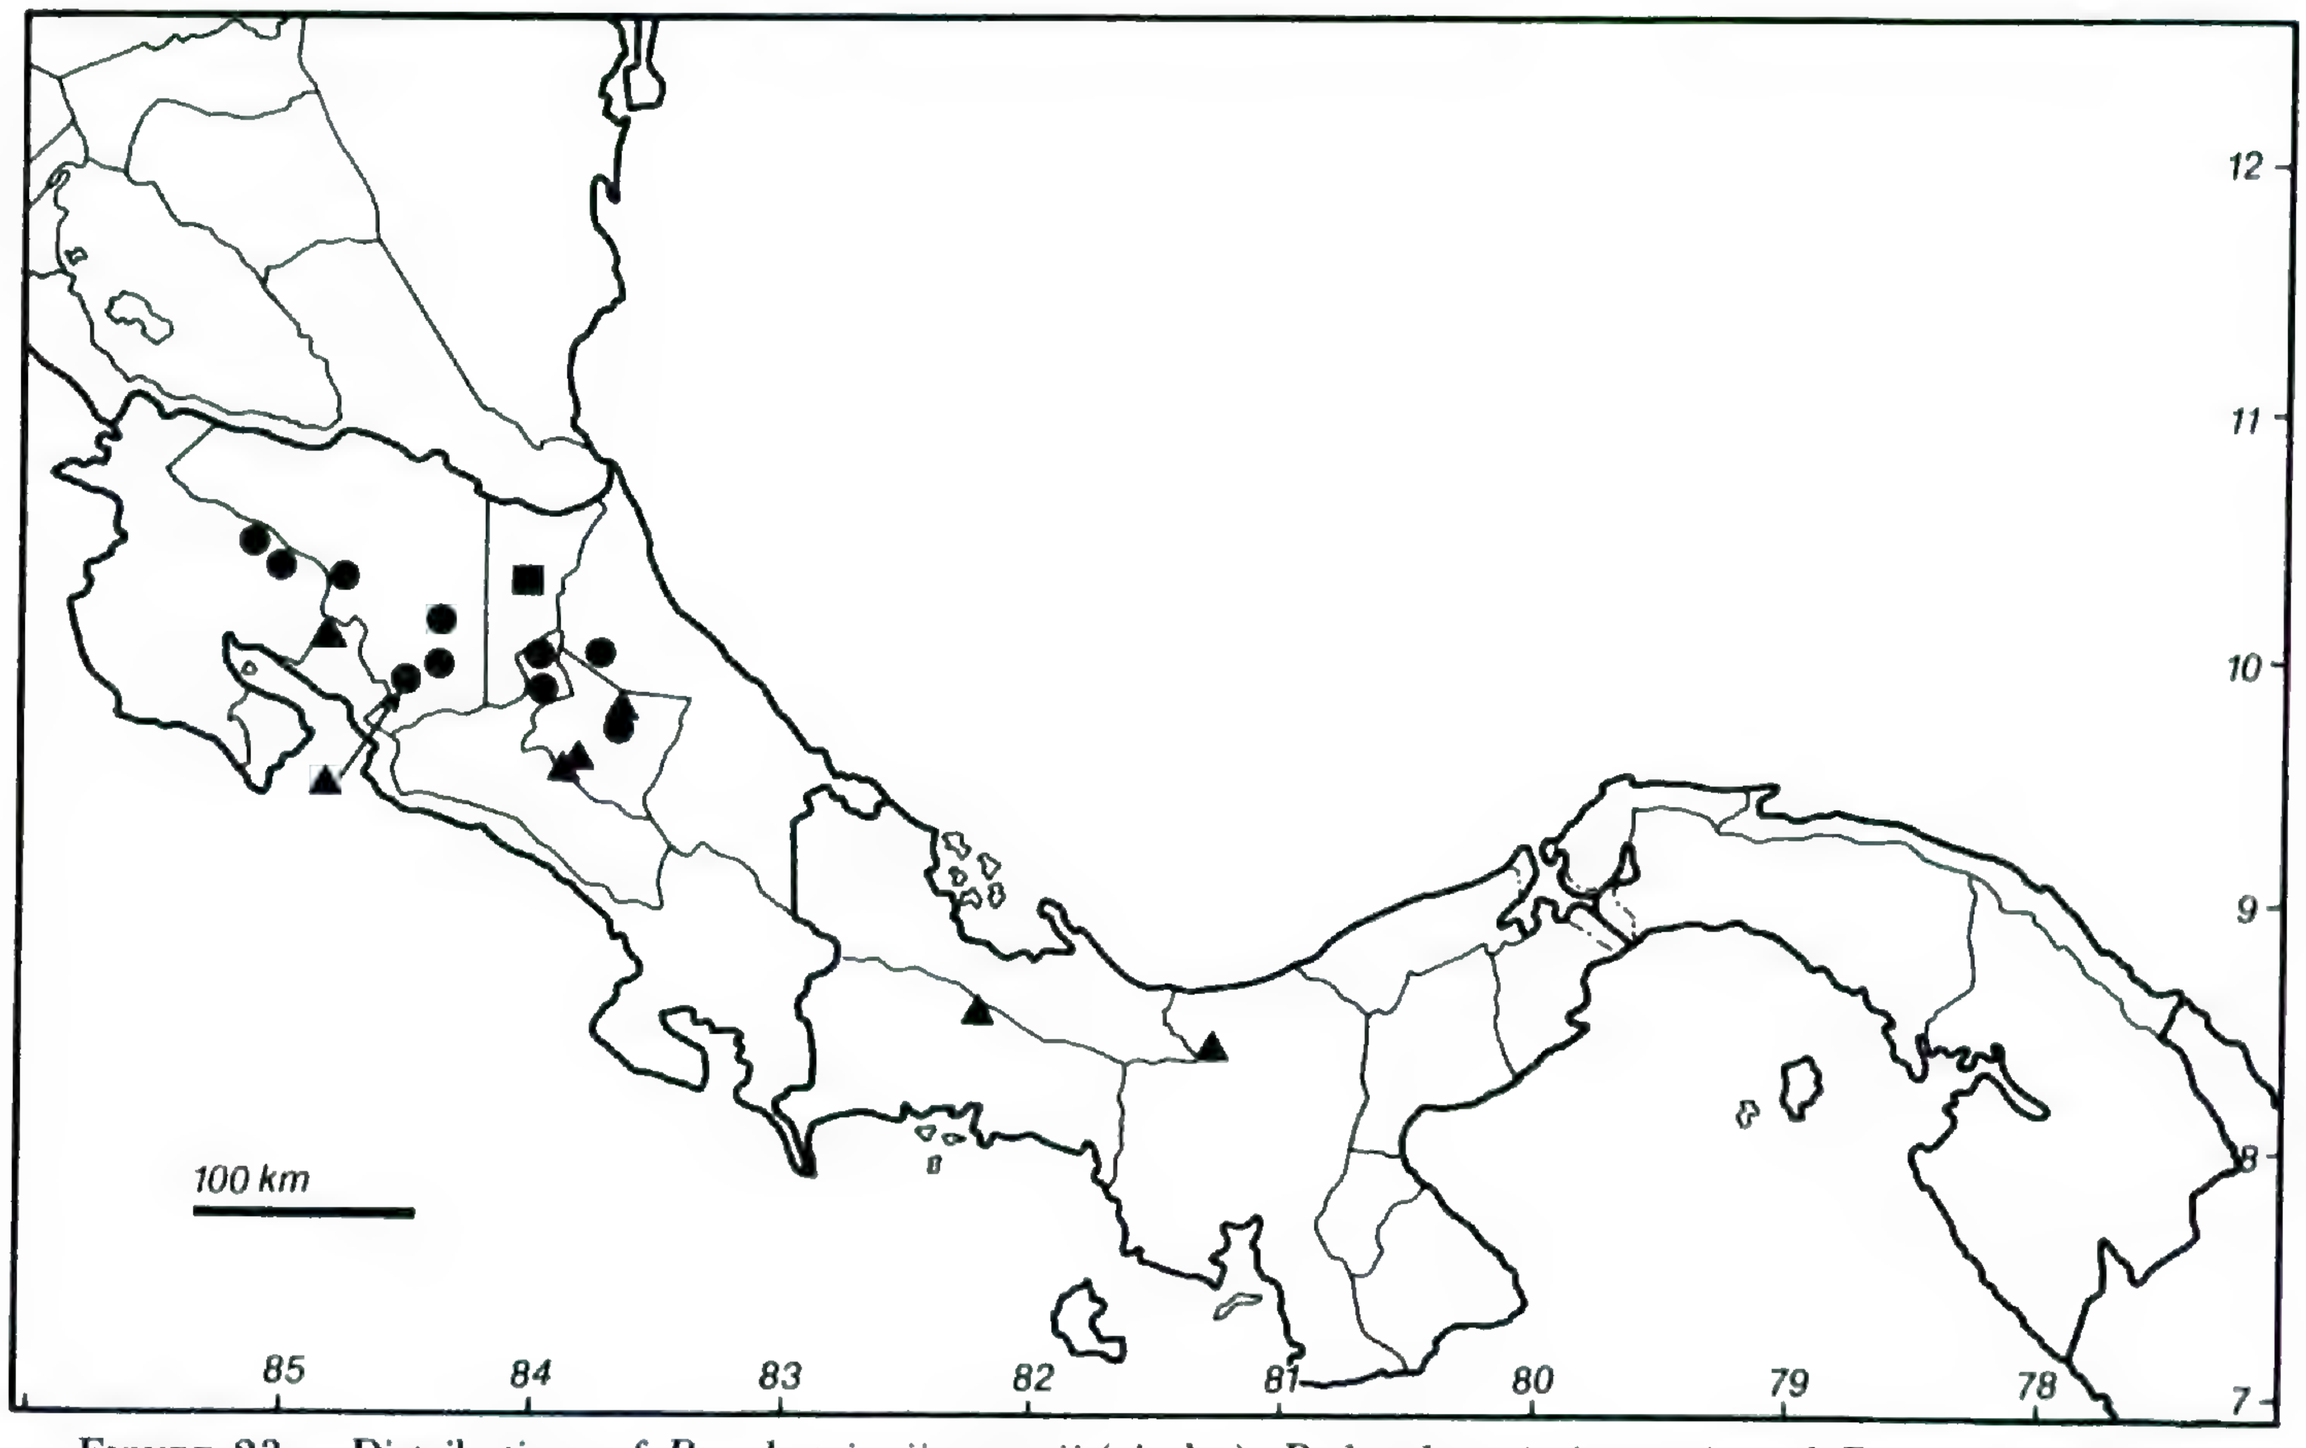

FIGURE 23. Distributions of *Psychotria jimenezii* (circles), *P. laselvensis* (square), and *P. orosiana* (triangles).

redia: Finca La Selva, OTS field station, Río Puerto Viejo just E of its junction with Río Sarapiquí, ca. 100 m, 19 May 1980 (fl), *Hammel 8706* (holotype, DUKE; isotype, CR). Figure 23.

Shrub 1.5–4 m tall; young stems glabrous, the bark smooth; stipules triangular, 3–4 × 3 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* subsessile to petiolate; petioles 1–7 mm long, glabrous, grooved above; blades membranous to chartaceous, elliptic, the apex acuminate, the base caudate to subcordate, (5–)7.5–13(–16) × (1.5–)2.5–5 cm, glabrous above and below, drying red-black; secondary veins (8–)10–13 pairs, diverging (65°–)80°–85°, brochidodromous, constantly arcuate, prominulous below, glabrous, the axils often with domatia below; tertiary veins evident, reticulate. *Inflorescences* terminal, spreading panicles of cymes; panicle branched to 4 degrees; main axis 6.5–15 cm long, the peduncle 4–9 cm long; secondary axes in 4–5 ranks, the first-rank axes 2 or 4, the longer pair 1.8–4.2 cm long, the shorter pair when present 0.5–0.7 cm long, the second-rank axes 2 or 4, the longer pair 0.6–1.8 cm long, the shorter pair when present 0.2 cm long, the third-rank axes 2, 0.3–0.9 cm long, the fourth-rank axes 2, 0.1–0.4 cm long, the fifth-rank axes 2, 0.2 cm long; cymes branched to 1 degree; bracts lanceolate to triangular, 2–3 mm long, glabrous; bracteoles lanceolate, 0.5–1 mm long, glabrous. *Flowers* pedicellate, the pedicels ca. 0.5 mm long; calyx cup-shaped, the tube 0.3 mm long, the lobes 5, triangular, barely evident, minutely ciliate; corolla white, the tube cylindrical, 2.5–3 × 1.2 mm, white pubescent in throat, the lobes 5, lanceolate, 2 × 1 mm; stamens 5, the filaments 2 mm long in pins, 3–3.5 mm long in thrums, the anthers 1–1.2 mm long; style 5–5.5 mm long in pins, 2.5–3 mm long in thrums, the branches linear, recurved. *Fruit* not seen.

Distribution (Fig. 23). Known only from the type locality, the Organization for Tropical Studies field station at Finca La Selva, Río Puerto Viejo, Heredia, Costa Rica, at ca. 100 m elevation in tropical wet forest with equatorial climate. *Psychotria laselvensis* has been collected in flower February–May and with immature fruit in July.

Additional specimens examined. COSTA RICA. HEREDIA: Finca La Selva, OTS field station, Río Puerto Viejo, 100 m, 1 May 1981 (fl), *Folsom 9958* (CR, DUKE); 4 May 1981 (fl), *Folsom 10004* (DUKE); 18 Feb. 1980 (fl), *Hammel 7778* (DUKE); 1 July 1981 (early fr), *Hammel 10938* (DUKE); 27 Mar. 1982 (fl), *Hammel 11491* (DUKE).

Psychotria laselvensis may be recognized by its resemblance to *P. graciliflora* and *P. orosiana* and its generally larger inflorescences and leaves. It differs from *P. orosiana* in having leaf blades

to 13(–16) cm (vs. 10.5 cm) long, more secondary veins (usually 10–13 vs. 7–9), inflorescence secondary axes commonly 4 (vs. 2) in the first rank, and usually shorter corolla tubes (2.5–3 vs. 2.5–5 mm). These three closely related species—*P. graciliflora*, *P. orosiana*, and *P. laselvensis*—form a continuum with regard to many quantitative characters, but their recognition as species is straightforward.

The exserted pistil in the pin morph is conspicuously longer than the exserted stamens in the thrum (5–5.5 vs. 3.5–4 mm).

21. Psychotria liesneri Dwyer, Ann. Missouri Bot. Gard. 67: 387. 1980. TYPE: PANAMA. PANAMÁ: NE of town of Cerro Azul, 20 km by road from Interamerican Hwy., 10 Dec. 1974 (fr), *Mori & Kallunki 3658* (holotype, MO). Figure 22.

Shrub 2–3 m tall; young stems minutely puberulent, the bark pale, irregularly fissured longitudinally; stipules sheathing, triangular-ovate, 2–2.5 × 1.5 mm, puberulent, red-brown ciliate, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 2–4 mm long, minutely puberulent, flat and furrowed above; blades membranous to subcoriaceous, elliptic, the apex long-acuminate, the base attenuate, the margin inrolled, (4–)4.5–6(–6.7) × (1–)1.5–2.2 cm, glabrous above, puberulent on midvein below, drying dark green-brown to red-brown; secondary veins 8–10 pairs, diverging 70°–80°, brochidodromous, straight then arcuate near margin, prominulous below, glabrous, the axils usually with often minutely ciliate domatia; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal, panicles of cymes; panicle branched to 2–3 degrees; main axis 1.5–3 cm long, the peduncle 1–1.5 cm long; secondary axes in (1–)2(–3) ranks, the first-rank axes 2, 0.3–1 cm long, the second-rank axes 2, 0.2–0.5 cm long, the third-rank axes 2, 0.2 cm long; bracts triangular, ca. 0.7 mm long, puberulent, ciliate; bracteoles triangular, to 0.5 mm long, puberulent, ciliate. *Flowers* sessile to subpedicellate, the pedicels to 0.5 mm long; calyx cup-shaped, the tube 0.3 mm long, the lobes 5, triangular, 0.3 × 0.7 mm, puberulent; corolla green-white, the tube cylindrical, 1.5 × 1 mm, white pubescent in throat, the lobes 5, lanceolate, 0.8 × 0.7 mm; stamens 5, the filaments 1.3–1.5 mm long in pins, not seen in thrums, the anthers 0.5 mm long; style 2.2 mm long in pins, not seen in thrums, the branches lanceolate. *Fruit* spherical when dry, (4–)5 mm long, (4–)5 mm diam., maturing red, drying black; persistent calyx inconspicuous; seed dorsal surface with 5–6 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 22). Known only from the type region, Cerro Jefe, Cerro Azul, and Goofy Lake (Lago Cerro Azul), eastern Panamá province, Panama, at 600–700 m elevation in premontane wet forest with equatorial-mountainous to tropical-equatorial climate. It has been collected in bud in November, in flower in February, with immature fruit in September, and in fruit in November–December.

Additional specimens examined. PANAMA. PANAMÁ: Cerro Jefe, nr. Río Indio, 630–660 m, 17 Feb. 1968 (fl), *Duke 15237* (MO—2 sheets); 8 mi. S of Goofy Lake toward Cerro Jefe, 26 Nov. 1966 (bud), *Dwyer 7083* (GH, MO); 26 Nov. 1966 (fr), *Dwyer 7098* (GH, MO, US); Cerro Jefe, ca. 1 mi. upstream from Frizzel's Finca Indio, 9 Sep. 1970 (early fr), *Foster & Kennedy 1851* (DUKE, F, MO, PMA); Cerro Azul, Feb. 1968 (fl), *Gómez-Pompa et al. 3436* (MEXU).

Psychotria liesneri may be recognized by its small elliptic (usually 4.5–6 × 1.5–2.2 cm) often subcoriaceous leaves with inrolled margins, brochidodromous secondary venation, and small (1.5–3 cm long) inflorescences with secondary veins usually in 2 ranks.

In both flowering collections, the negligible separation between style and stamens suggests that the species is long-homostylous instead of distylous.

22. Psychotria marginata Swartz, Prodr., 43. 1788. *Uragoga marginata* (Sw.) Kuntze, Revis. Gen. Pl. 2: 961. 1891. *Myrstiphyllum marginatum* (Sw.) Hitchc., Annual Rep. Missouri Bot. Gard. 4: 95. 1893. TYPE: Jamaicae australis: (fl), *Swartz s.n.* (holotype, S, n.v., photo, A; isotype, B–Willdenow 4068). Cf. also Swartz, Fl. Ind. Occid. 400. 1797. Figures 4b, 7h, 8, 20.

Psychotria nicaraguensis Bentham in Oersted, Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 34. 1853. *Uragoga nicaraguensis* (Benth.) Kuntze, Revis. Gen. Pl. 2: 957. 1891. TYPE: Nicaragua. San Juan, (fr), *Oersted 11634* (holotype, C, n.v., photos, GH, NY, US; isotype, K).

Shrub 1–3(–4) m tall; young stems glabrous, the bark smooth; stipules sheathing, lanceolate, 9–13 × 2.5–4 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.5–2(–2.5) cm long, glabrous, flat or grooved above; blades membranous, oblanceolate, the apex long-acuminate, the base attenuate, (8–)12–18(–20) × (3–)4–6.5(–7.5) cm, glabrous

above and below, the margin often ciliate, drying red-gray to sometimes dull red-brown; secondary veins (9–)12–14(–16) pairs, diverging (55°–)65°–75°, eucamptodromous, constantly arcuate, elevated below, glabrous, the axils usually with domatia along midvein below (Fig. 4b); tertiary veins evident to inconspicuous, orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, diffuse panicles of cymes (Fig. 7h); panicle branched to 5 degrees; main axis (7–)10–15 cm long, the peduncle 4–7 cm long; secondary axes in (4–)5–6 ranks, the first-rank axes 2(4), the longer pair 2–8 cm long, the shorter pair when present 0.5 cm long, the second-rank axes 2, (0.5–)1.5–5.5 cm long, the third-rank axes 2, (0.4–)0.7–2.5 cm long, the fourth-rank axes 2, (0.2–)0.4–1 cm long, the fifth-rank axes 2, 0.2–0.7 cm long, the sixth-rank axes 2, 0.3 cm long; cymes branched to 1–2 degrees; bracts triangular, 1.5 mm long, glabrous; bracteoles lanceolate, 0.3 mm long, glabrous. *Flowers* pedicellate, the pedicels 1–2.5 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 5, not evident to triangular, to 0.2 mm long, often puberulent without; corolla pale yellow, the tube cylindrical, 2–2.5 × 1–1.2 mm, short white pubescent in throat, the lobes 5, lanceolate, 1–1.5 × 0.7 mm, stamens 5, the filaments 1.5–1.8 mm long in pins, 3 mm long in thrums, the anthers 0.8–1 mm long; style 4–4.5 mm long in pins, 2–2.5 mm long in thrums, the branches linear, recurved (Fig. 8). *Fruit* when dry spherical to slightly ellipsoid, 3.5–4 mm long, 3.5–4 mm diam., maturing red, drying black; persistent calyx inconspicuous or sometimes a beak to 0.7 mm long; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 20). Widespread from Mexico through Panama, at elevations of 0–1,000 m, usually below 500 m, in tropical moist to premontane rainforest with equatorial to tropical climate. *Psychotria marginata* occurs also in Cuba, Jamaica, Colombia, Venezuela, Ecuador, and Peru. It has been collected in flower throughout the year, primarily September–April, and in fruit throughout the year.

Island, Playa Rosario, 26 Aug. 1970 (fl), *Foster 1614* (DUKE).

Psychotria marginata may be recognized by its oblanceolate long-acuminate leaves drying usually red-gray, eucamptodromous secondary venation with axillary domatia, large (usually 10–15 cm long) diffuse panicles of cymes with delicate axes diverging at right angles, and small (3.5–4 mm) spherical fruit drying black. *Psychotria marginata* is remarkably uniform in qualitative and quantitative aspects throughout its broad range.

The exserted pistils in the pin morph are longer than the exserted stamens in the thrum (4–4.5 vs. 3.5 mm).

23. Psychotria orosiana Standley, J. Wash Acad. Sci. 15: 288. 1925. TYPE: Costa Rica. Cartago: vic. Orosí, 30 Mar. 1924 (fl), *Standley 39803* (holotype, US). Figures 2f, 10d, 23.

Shrub or small tree 1.5–4(–5) m tall; young stems glabrous, the bark smooth; stipules lanceolate, 3–5 × 1–2 mm, biaristate, with fringed extensions, caducous, leaving a pale ridge with red-brown fringe (Fig. 2f). *Leaves* sessile to subsessile; petioles to 3 mm long, glabrous; blades membranous, elliptic to oblanceolate, the apex acuminate, the base attenuate to subcordate, (4.5–)5.5–10.5 × 1.7–3.8 cm, glabrous above and below, drying green-black; secondary veins 7–9 pairs, diverging 80°–90°, brochidodromous, constantly arcuate, barely elevated below, glabrous, the axils with domatia below; tertiary veins evident to inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3–4 degrees; main axis 3.5–10 cm long, the peduncle 2.5–7.5 cm long; secondary axes in (2–)3–4(–5) ranks, the first-rank axes 2(4), 1–2.5 cm long, the shorter pair when present 0.7 cm long, the second-rank axes 2, 0.3–1.5 cm long, the third-rank axes 2, 0.2–1 cm long, the fourth-rank axes 2, 0.2–0.4 cm long, the fifth-rank axes 2, 0.2 cm long; cymes branched to 1 degree; bracts triangular, to 1.5 mm long, fringed; bracteoles lanceolate, 0.5 mm long, glabrous. *Flowers* sessile to pedicellate, the pedicels 0.5–2.5 mm long; calyx cylindrical, the tube 0.5 mm long, the lobes 5, triangular to barely evident, to 0.3 mm long, the lobes puberulent outside; corolla yellow-white, the tube cylindrical, 2.5–5 × 1–1.5 mm, white pubescent in throat, the lobes 5, lanceolate, 1.5 × 1 mm; stamens 5, the filaments 2.5–3.5 mm long in pins, 3.5 mm long in thrums, the anthers 0.7–1 mm long; style (4–)5.5–6.5 mm long in pins, 2 mm long in thrums, the branches short, linear. *Fruit* when dry ellipsoid, 4.5–5(–6) mm long, 3.5–4(–5) mm diam., maturing red, drying black; persistent calyx a minute beak; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows (Fig. 10d).

Distribution (Fig. 23). Known from the central cordillera in Costa Rica and western Panama, at 400–1,400 m elevation, usually above 1,000 m, in premontane to low montane wet to rainforest with equatorial-mountainous climate. It has been collected in flower January–June and September and in fruit in March, June, September, and October.

Selected specimens examined. COSTA RICA. ALAJUELA: La Palma de San Ramón, 1,275 m, 30 May 1927 (fl), *Brenes 5534* (CR, F, NY). CARTAGO: Qda. Rojas, 1 km W of Muñeco, 1,240 m, 15 Sep. 1969 (fl), *Lent 1785* (CR, MO, NY); 24 km NE of Turrialba on hwy. to Limón, 9°58′N, 83°34′W, 450–525 m, 10 May 1983 (fl), *Liesner et al. 15377* (CR, MO); vic. Orosí, 30 Mar. 1924 (fl), *Standley 39768* (US). PUNTARENAS: hills NE of Quaker settlement of Monte Verde, 8 May 1971 (fl), *J. Utley 148* (DUKE). PANAMA. CHIRIQUÍ: Proyecto Fortuna, propriedad del IRHE, desde la finca Pittí hasta el filo del Cerro Fortuna, 8°45′N, 82°15′W, 1,000–1,200 m, 25 Sep. 1976 (fl, fr), *M. Correa A. et al. 2726* (MO); Fortuna dam site, 1,400–1,500 m, 14 Sep. 1977 (fl), *Folsom et al. 5454* (MO); La Fortuna project, 1,300–1,400 m, 23 Mar. 1978 (fr), *Hammel 2221* (MO); behind Vivero Forestal de Boquete, 12 km N of Los Planes del Hornito, IRHE Fortuna Hydroelectric Project, 8°43′N, 82°14′W, 17 June 1982 (fl, fr), *Knapp & Vodicka 5522* (MO); lower slopes of Cerro Fortuna, IRHE Fortuna Project, 1,150 m, 18 June 1982 (fl), *Knapp & Vodicka 5595* (MO). VERAGUAS: valley of Río Dos Bocas, 11–13 km beyond Agriculture School at Santa Fe, 350–500 m, 25 July 1974 (early fr), *Croat 25731* (GH, MO).

Psychotria orosiana may be recognized by its resemblance to *P. graciliflora*—leaves drying blackish, secondary veins diverging ca. 80°, inflorescence axes delicate—and by its larger (3.5–10 vs. 3–5 cm long) inflorescences, longer corolla tube (2.5–5 vs. 2–2.5 mm), and seed dorsal surfaces with deeper longitudinal furrows having acute longitudinal ridges between.

The reproductive parts at both levels are longer in pin morphs than in thrums.

24. Psychotria parvifolia Bentham in Oersted, Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 35. 1853. *Mapouria parvifolia* (Benth.) Oerst., Amér. Centr. p. 17, t. 14, fig. 1. 1863. *Uragoga levyi* Kuntze, Revis. Gen. Pl. 2: 956. 1891. Not *U. parvifolia* (Muell. Arg.) Kuntze (based on *Rud-*

gea parvifolia Muell. Arg.). TYPE of *P. parvifolia* Benth.: Costa Rica. Alajuela: nr. Naranjo, ca. 1,350 m, Apr. 1847 (fl), *Oersted 11637* (holotype, C, n.v., photo, F neg. 22842; isotype, K). Figure 22.

Shrub 1.5–3 m tall; young stems ferrugineous-pubescent, the bark irregularly furrowed; stipules sheathing, lanceolate, (2.5–)4–6 × (1–)1.2–1.7 mm, ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 2–10 mm long, ferrugineous-pubescent, flat above; blades membranous, elliptic to slightly obovate, the apex acute, the base cuneate, (1–)1.5–5.2 × (0.6–)0.8–2 cm, glabrous above and below, the midvein often ferrugineous-puberulent, drying dark green-brown to red-brown, paler below; secondary veins 3–5 pairs, diverging 45°–50°, brochidodromous, constantly arcuate, inconspicuous to not evident below, glabrous, the axils lacking domatia or hairs; tertiary veins not evident. *Inflorescences* terminal or pseudoaxillary, panicles of cymes or glomerules; panicle branched to 2–3 degrees; main axis (2–)4–12 mm long, the peduncle lacking; secondary axes in 1–2 ranks, the first-rank axes (1)2, 1–4 mm long, the second-rank axes 2, 1–3 mm long; cymes branched to 1 degree; bracts lanceolate, ca. 2 mm long, glabrous; bracteoles lanceolate, 1 mm long, glabrous. *Flowers* pedicellate, the pedicels 0.5–3 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 4, triangular, to 0.3 mm long, puberulent; corolla white, the tube cylindrical, 2.5–4 × 1–1.5 mm, white pubescent in throat, the lobes 4, lanceolate, 1.5–2 × 0.8 mm; stamens 4, the filaments 2 mm long in pins, 3.5–5 mm long in thrums, the anthers 0.6–0.7 mm long; style 5 mm long in pins, 2–3.5 mm long in thrums, the branches linear. *Fruit* when dry spherical, 4–5 mm long, 4–5 mm diam., maturing red, drying dark red-brown; persistent calyx not evident or a minute beak; seed dorsal surface with 6–8 shallow longitudinal furrows, the ventral surface with 2 deep and sometimes 2–4 shallow longitudinal furrows.

Distribution (Fig. 22). Known from the central cordillera in Costa Rica and western Panama, at 1,300–2,000 m elevation in regions of low montane rainforest with equatorial-mountainous climate. *Psychotria parvifolia* has been collected in flower April–September and December and in fruit December–May.

Selected specimens examined. COSTA RICA. ALAJUELA: La Palma de San Ramón, Socorro, 22 Aug. 1927 (st), *Brenes 5681* (CR, F, NY); 15 km NW of San Ramón by air, Cerro Azahar, Río San Pedro, 10°09′N, 84°34′W, 1,400–1,500 m, 14 May 1983 (fl), *Liesner et al. 15585* (CR, MO); vic. Psychotria parvifolia may be recognized by its small (usually 1.5–5.2 × 0.8–2 cm) membranous leaves with 3–5 inconspicuous secondary veins, minute (usually 0.4–1.2 cm long) inflorescences, and spherical fruits 4–5 mm in diameter. Collections from Chiriquí, Panama, show more slender inflorescence axes, longer (3 mm) pedicels plus longer corolla tubes and filaments and styles than from Costa Rica.

The exserted pistil in the pin morph is usually longer than the exserted stamens in the thrum (5 vs. 3.8–5.3 mm).

25. Psychotria philacra Dwyer, Ann. Missouri Bot. Gard. 67: 412. 1980. TYPE: Panama. Darién: Cerro Tacarcuna S slope, ridgetop well below summit, 1,250–1,450 m, 26 Jan. 1975 (fr), *Gentry & Mori 13916* (holotype, MO). Figure 22.

Shrub 3 m tall; young stems glabrous or red-brown puberulent, the bark mottled; stipules lanceolate, 4 × 1.2 mm, ferrugineous-pubescent, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 4–10 mm long, glabrous to sparsely puberulent, flat above; blades membranous, elliptic, the apex acuminate, the base attenuate, 5–7 × 1.7–2.7 cm, glabrous above and

below, drying dull red-brown; secondary veins 6–7 pairs, diverging 60°–70°, eucamptodromous, constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins not evident. *Inflorescences* terminal, seen only with few fruits. *Flowers* not seen. *Fruit* when dry obloid, 4.5–5.5 mm long, 5–6 mm diam., maturing red, drying dark red-brown; persistent calyx inconspicuous or a minute beak; seed dorsal surface with 4 deep irregular and several shallow irregular longitudinal furrows, the ventral surface with 2 deep and several irregular longitudinal furrows.

Distribution (Fig. 22). Known only from the type collection from Cerro Tacarcuna, eastern Darién, Panama, at 1,250–1,450 m elevation in low montane rainforest with equatorial-mountainous climate. It was collected in fruit on January 26.

Psychotria philacra may be recognized by its small elliptic (5–7 × 1.7–2.7 cm) leaves drying dull red-brown and with 6–7 secondary veins, obloid fruits, and seeds with shallow irregular furrows on both surfaces.

Group 4. The *remota* Group

The description for the group in Mesoamerica is that of the lone species, *Psychotria remota*. Key recognition characters include leaves drying glossy red-brown and relatively few secondary veins for the large size of the blade. This group is larger in South America, including also *P. anceps* Kunth and *P. cupularis* (Muell. Arg.) Standl.

Psychotria remota appears normally distylous, with no floral-part-length asymmetry between the morphs.

26. Psychotria remota Bentham, J. Bot. (Hooker) 3: 225. 1841. *Mapouria remota* (Benth.) Muell. Arg., Flora 59: 459. 1876. Cf. also Martius, Fl. Bras. 6(5): 407. 1881. *Uragoga remota* (Benth.) Kuntze, Revis. Gen. Pl. 2: 962. 1891. TYPE: Guiana: on the Río Negro, (fl), *Schomburgk 963* (holotype, K, n.v., photo, NY neg. no. 3421; isotypes, F, W, n.v.). Figures 4a, 7j, 10f, 24.

Psychotria alboviridula K. Krause, Notizbl. Koenigl. Bot. Gart. Berlin 6: 208. 1914. TYPE: Brazil: Im Gebiet des Alto Acre, Seringal, San Francisco, Sep. 1911 (fl), *Ule 9846* (holotype, B, destroyed, fragment, F, photo, F neg. no. 468; isotype, US).

Tree 1.5–6 m tall; young stems glabrous to sparsely minute-puberulent, the bark mottled, slightly ridged longitudinally; stipules sheathing, triangular, acuminate or biacuminate, 4–6 × 2.5–4 mm, glabrous, sometimes sparsely fringed, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.7–2.5 cm long, glabrous, flat or grooved above; blades membranous to subcoriaceous, elliptic, the apex long-acuminate, the base cuneate, (8–)11–24 × (3–)3.5–8(–9) cm, glabrous above and below, drying glossy red-brown; secondary veins (7–)8–12 pairs, diverging 60°–70°, eucamptodromous to brochidodromous, constantly arcuate, prominent below, glabrous, the axils usually with prominent domatia below (Fig. 4a); tertiary veins evident, orthogonal reticulate to percurrent, the intersecondaries often conspicuous. *Inflorescences* terminal, elongate panicles of cymes (Fig. 7j); panicle branched to 4 degrees, the axes winged; main axis 7–15 cm long, the peduncle 3–5 cm long; secondary axes in (4–)6–7 ranks, the first-rank axes 2(4), 1–5.5 cm long, the shorter pair when present 1.2 cm long, the second-rank axes 2, (0.3–)0.5–1 cm long, the third-rank axes 2, 0.3–0.9 cm long, the fourth-rank axes 2, 0.2–0.6 cm long, the fifth-rank axes 2, 0.1–0.4 cm long, the sixth-rank axes 2, 0.1–0.3 cm long, the seventh-rank axes 2, 0.1–0.3 cm long; cymes branched to 1(–2) degrees; bracts and bracteoles triangular, 0.5–1.5 mm long, ciliate. *Flowers* pedicellate, the pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 0 or 5, not evident to triangular, to 0.3 mm long, minute puberulent; corolla yellow-green, the tube cylindrical, 1.5 × 1 mm, white pubescent in throat, the lobes 5, lanceolate, 1 × 0.6 mm; stamens 5, the filaments 1.5 mm long in pins, 2.5 mm long in thrums, the anthers 0.3–0.5 mm long; style 2.5 mm long in pins, 2 mm long in thrums, the branches club-shaped. *Fruit* ellipsoidal when dry, (6–)7–9 mm long, (4–)5–6 mm diam., maturing dark red, drying dark red-brown; persistent calyx not evident or rarely a minute beak; seed dorsal surface with 3 deep longitudinal furrows, the ventral surface with 2 longitudinal furrows (Fig. 10f).

Distribution (Fig. 24). Scattered distribution in Caribbean Costa Rica and Panama, at 20–1,000 m elevation in tropical moist to premontane wet forest with equatorial to tropical-equatorial climate. It is more abundant in Colombia, Venezuela, the Guianas, Ecuador, Peru, and Brazil. In Central America, it has been collected in flower in March, April, September, and October and in fruit in March–May and September.

Selected specimens examined. COSTA RICA. HEREDIA: Caño Negro, Río Sarapiquí, 23 km N of Puerto Viejo, 20 m, 19 Apr. 1974 (early fr), *Hartshorn 1444* (CR, MO). LIMÓN: 7 km SW of Bribrí, 100–250 m, 4 May

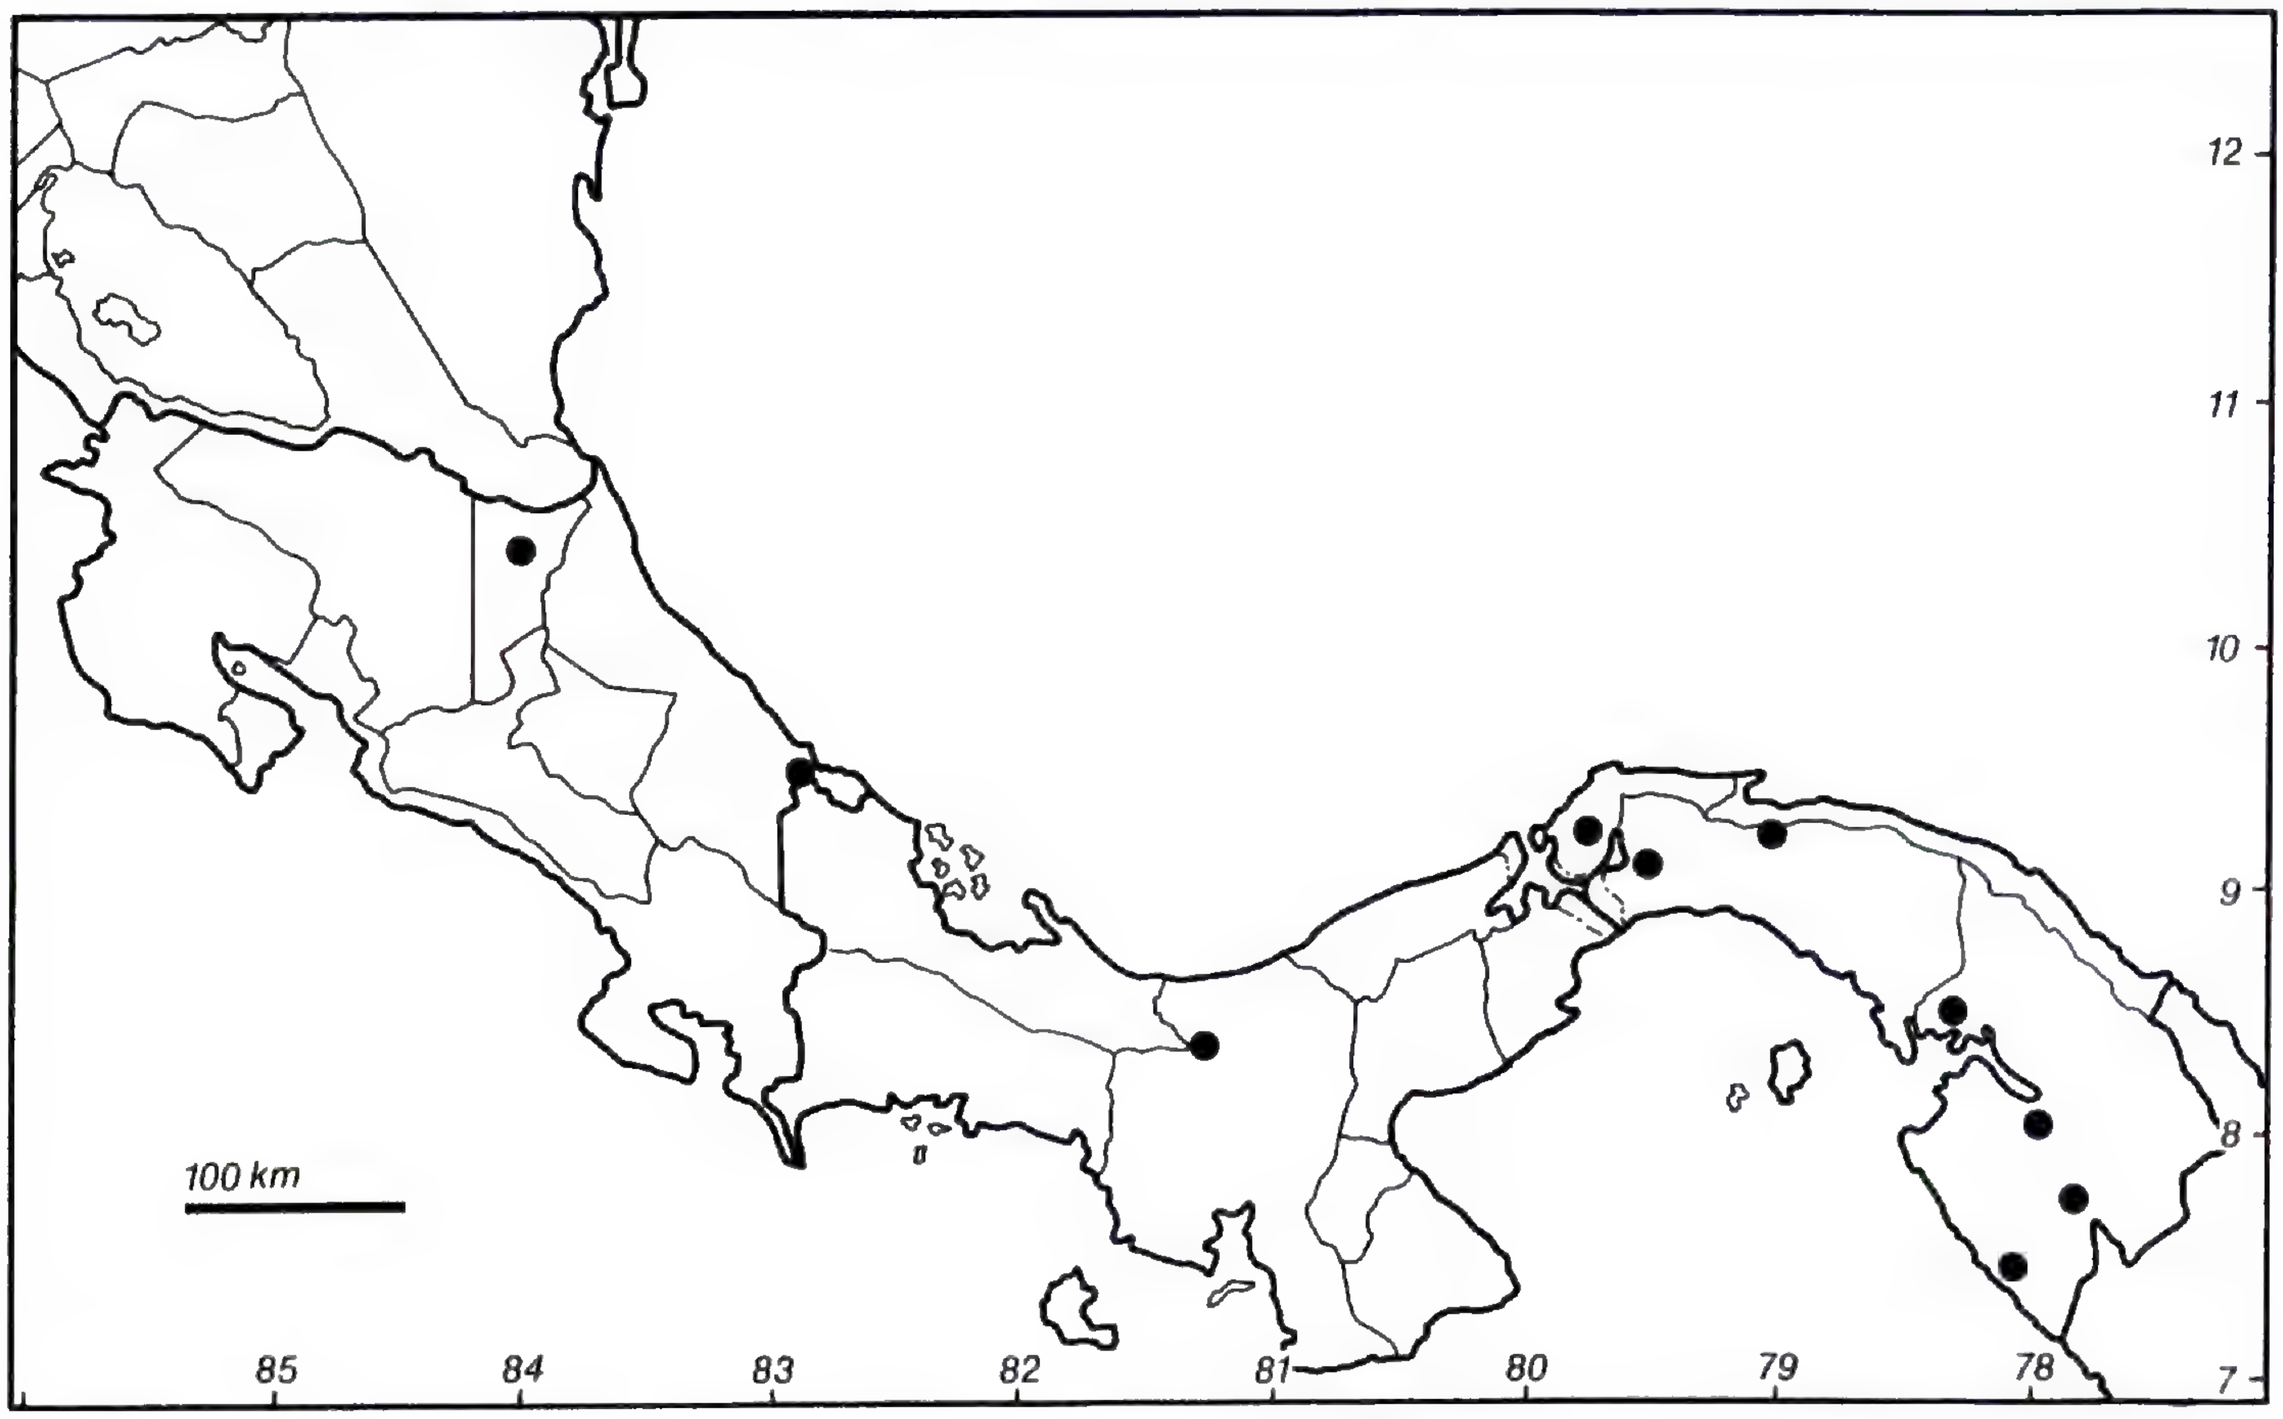

FIGURE 24. Distribution of *Psychotria remota* in Costa Rica and Panama.

1983 (fr), *L. D. Gómez et al. 20381* (MO). PANAMA. COLÓN: Santa Rita lumber rd., ca. 15 km E of Colón, 5 Oct. 1969 (fl), *Dressler & Lewis 3732* (MO, US). PANAMÁ: nr. Lago Cerro Azul (Goofy Lake), 9°10′N, 79°25′W, 500–600 m, 3 Mar. 1983 (fl), *Hamilton & Krager 3197* (CR, MO); rd. from El Llano to Cartí-Tupile, 300–500 m, 30 Mar. 1973 (fr), *Liesner 1280* (F, MO, NY); rd. past Cerro Azul, 28 Sep. 1974 (fr), *Mori & Kallunki 2188* (GH, MO): El Llano–Cartí rd., 16–18.5 km N of Pan-Am. Hwy. at El Llano, 400–450 m, 28 Mar. 1974 (fr), *Nee & Tyson 10937* (F, MO). VERAGUAS: 0.6 mi. beyond Escuela Agricola Alto Piedra nr. Santa Fe, 730 m, 4 Apr. 1976 (fr), *Croat & Folsom 34052* (MO, NY).

The inclusion of *P. alboviridula* within *P. remota* is discussed by Steyermark (1972; Mem. New York Bot. Gard. 23: 477).

Psychotria remota may be recognized by its moderately large (usually 11–24 cm long) elliptic leaves drying glossy red-brown, few (usually 8–12) secondary veins generally with prominent domatia in the axils, reduced (except for the first rank) and winged secondary inflorescence axes, and large (usually 7–9 mm long) ellipsoidal fruit.

GROUP 5. THE *NERVOSA* GROUP

Shrub; young stems glabrous or *red-brown to brown tomentose to puberulent*; stipules usually sheathing, linear (Fig. 2c) or ovate, the apex sometimes bilobed or biaristate, uniform in color (except *P. fosteri*, with a darker red-brown midrib), glabrous or fringed or red-brown pubescent, caducous. *Leaf* blades obovate or elliptic or oblanceolate, drying red-brown to green-brown (often chalky yellow-green in *P. fruticetorum*), sometimes pale below; secondary veins (4–)5–17 pairs, diverging 35°–65° (except 70°–80° in *P. fosteri*), eucamptodromous or brochidodromous (with collector vein in *P. chagrensis* and *P. fosteri*), the axils usually with tufts of hairs (lacking in *P. chagrensis*, *P. fosteri*, and usually *P. nervosa*); tertiary veins reticulate or percurrent. *Inflorescences* panicles of cymes (often contracted in *P. nervosa*) or fascicles of flowers (in *P. chagrensis* and *P. fosteri*), *not pedunculate* (except *P. erythrocarpa*, *P. fruticetorum*, and often *P. jinotegensis*); *secondary axes usually in 1 pair* or less commonly 2 size-differentiated pairs per rank (4 equal axes per rank rarely in *P. nervosa*); bracts conspicuously enlarged in *P. chagrensis*, *P. fosteri*, and *P. fruticetorum*. *Corolla* tubes 2–4 mm long (6–7 mm in *P. chagrensis*), the lobes without apical extensions. *Fruit ellipsoid when dry* (narrow in *P. nervosa*); *persistent calyx a tube to 5 mm long* (Fig. 9d)

or a beak or inconspicuous; *seed dorsal surface with 4–5 deep longitudinal furrows* (or 6–8–many irregular furrows in *P. aguilarii* and *P. jinotegensis*), the ventral surface with 2 deep or shallow longitudinal furrows, sometimes incompletely divided in *P. nervosa* or with additional irregular furrows in *P. jinotegensis*.

Of the nine species, three fairly widespread ones do not closely resemble any others: *Psychotria fruticetorum*, with its biaristate stipules, leaves drying chalky yellow-green, pedunculate inflorescences, and bracts as long as 8 mm; *P. erythrocarpa*, with its linear stipules and pedunculate inflorescences often of glomerules; and *P. jinotegensis*, with its often pedunculate inflorescences and many irregular furrows on both seed surfaces. The *P. chagrensis* complex shares a collector vein, an absence of tufts of hairs in the axils of the secondary veins, and inflorescences of fascicles of flowers and with bracts conspicuously enlarged; the complex comprises the widespread *P. chagrensis* and *P. fosteri*, endemic to Coiba Island, Panama (Fig. 26). The *P. nervosa* complex includes that widespread species plus *P. aguilarii* (southern Guatemala), *P. boquetensis* (western Panama), and *P. mirandae* (southern Mexico); none of them deviates morphologically from the predominant character states of the group.

Of the nine species in the group, seven appear distylous. Of those, *Psychotria fruticetorum* has longer exserted parts in the pins than in thrums, and *P. chagrensis* has longer inserted parts in the pins. One species, *P. mirandae*, appears to be thrum-monomorphic. Only *P. fosteri* may not be evaluated for this character due to lack of adequate flowering material.

27. Psychotria aguilarii Standley & Steyermark, Publ. Field Mus. Nat. Hist., Bot. Ser. 23: 23. 1943. TYPE: Guatemala. Chimaltenango: rd. between Chimaltenango and San Martín Jilotepeque, 1,500–1,700 m, 22 Dec. 1940 (fr), *Standley 80900* (holotype, F). Figure 25.

Shrub 1–2(–6) m tall; young stems glabrous, the bark pale with shallow fissures; stipules sheathing, ovate, 7–10 × 2–4 mm, lacking fringe, glabrous, caducous, leaving a pale ridge with irregular fringe. *Leaves* petiolate; petioles 2–4(–7) mm long, glabrous, flat above; blades membranous, narrow elliptic to obovate, the apex acuminate, the base attenuate, the margins crenulate, (8–)11–13 × (2.5–)3–4 cm, glabrous above, sparsely puberulent along midvein below, drying red-brown or sometimes greenish; secondary veins 8–11 pairs, diverging (45°–)50°–60°, eucamptodromous, slightly arcuate, prominent below, glabrous, the axils with minute tufts of hair; tertiary veins evident, reticulate to slightly percurrent. *Inflorescences* terminal or pseudoaxillary, sparse panicles of cymes; panicle branched to 2–3 degrees; main axis 3–4 cm long, the peduncle lacking; secondary axes in 2 ranks, the first-rank axes 2, 2–2.2 cm long, the second-rank axes 2, 0.5–1.2 cm long; cymes branched to 1–2 degrees; bracts and bracteoles minute, linear, ca. 0.2 mm long, glabrous. *Flowers* sessile; calyx cup-shaped, the tube 0.5–1 mm long, the lobes 5, acute triangular, 0.2–0.5 × 0.3 mm, glabrous; corolla greenish white, the tube cylindrical, 3–3.5 × 1 mm, white pubescent in throat, the lobes 5, acute triangular, 1–1.5 × 0.7 mm; stamens 5, the filaments 2 mm long in pins, 3.5 mm long in thrums, the anthers 1 mm long; style 3.5 mm long in pins, 2 mm long in thrums, the branches spathulate. *Fruit* when dry ellipsoid, 5–6 mm long, 3–4 mm diam., maturing dark red, drying dark brown; persistent calyx not evident; seed dorsal surface with many irregular shallow longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 25). Known only from the Guatemalan states of Chimaltenango, Escuintla, Guatemala, Huehuetenango, and Sacatepéquez, at elevations of 1,000–1,500 m, in tropical-mountainous climate. *Psychotria aguilarii* has been collected in flower in February and May and in fruit in August and December.

Additional specimens examined. GUATEMALA. ESCUINTLA: 6 km W of San Vicente Pacaya, 1,250 m, 31 May 1970 (fl), *Harmon 2431* (MO). GUATEMALA: nr. Finca La Aurora, 1,500 m, 1938–1939 (fr), *I. Aguilar 126* (F); 1939 (early fr), *I. Aguilar 215* (F). HUEHUETENANGO: Paso del Boquerón, along Río Trapichillo, below La Libertad, 1,200–1,300 m, 21 Aug. 1942 (fr), *Steyermark 51133* (F). SACATEPÉQUEZ: nr. Barranco Hondo, SE of Alotenango, 1,000–1,260 m, 9 Feb. 1939 (fl), *Standley 65024* (F).

Psychotria aguilarii may be recognized first by its striking resemblance to *P. nervosa*. The former differs in being generally glabrous (as is *P. nervosa* sometimes) and in having leaves with crenulate leaf margins, inflorescence secondary axes in 2 (vs. 3–4) ranks, longer corolla tubes (3–3.5 vs. 2–3 mm), fruit less narrowly ellipsoidal (length/width = 1.5 vs. ca. 2.2), and seed dorsal surface with many irregular shallow furrows (vs. 4–5 regular furrows).

28. Psychotria boquetensis Dwyer, Ann. Missouri Bot. Gard. 67: 349. 1980. TYPE: Pan-

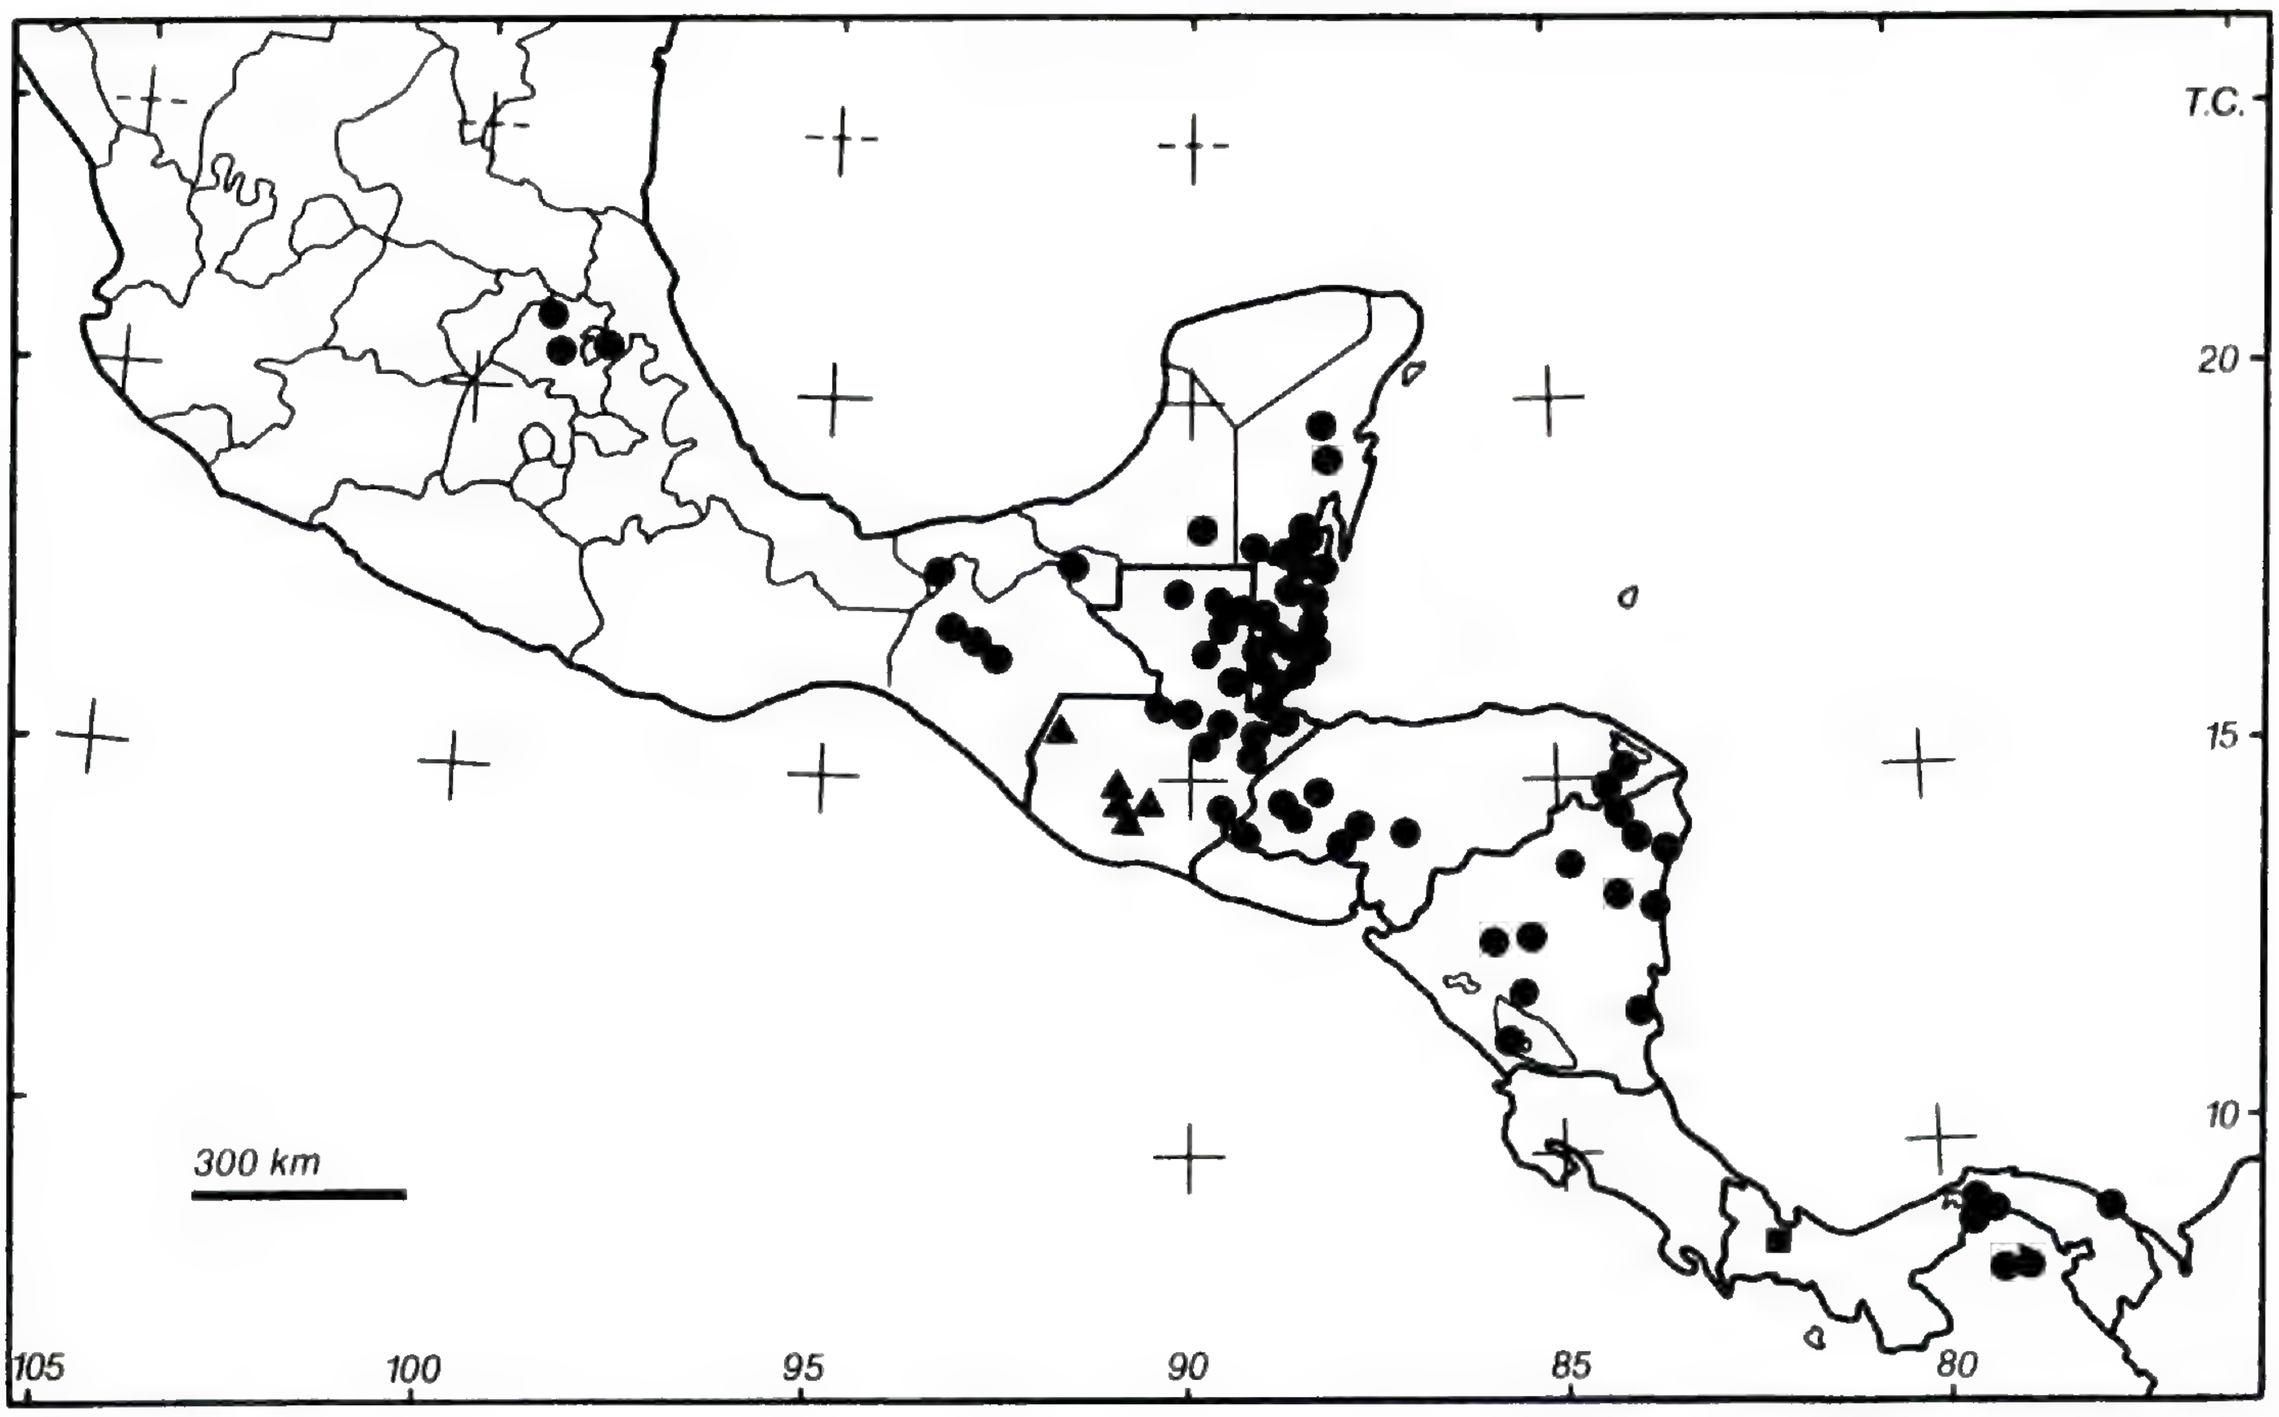

FIGURE 25. Distributions of *Psychotria aguilarii* (triangles), *P. boquetensis* (square), and *P. fruticetorum* (circles) in Mesoamerica.

ama. Chiriquí: Boquete, 1,080 m, 25 May 1938 (fl), *Davidson 709* (holotype, MO; isotypes, F, US). Figure 25.

Shrub 0.5–2 m tall; young stems brown tomentose, the bark gray, longitudinally grooved; stipules sheathing, ovate, bilobed with the lobes 2–6 mm long, (6–)8–11 × 2.5 mm, lacking fringe, glabrous or sometimes sparsely tomentose, caducous, leaving a pale ridge with red-brown fringe. *Leaves* subsessile; petioles 3–6 mm long, brown tomentose, flat or grooved above; blades membranous, elliptic to oblong, the apex long-acuminate, the base attenuate, (6–)9–15 × (1.5–)2–4 cm, glabrous to slightly puberulent along primary and secondary veins above, sparsely tomentose along veins below, the margins ciliate, drying red-brown, paler below; secondary veins (10–)12–15 pairs, diverging 40°–50°, eucamptodromous, slightly arcuate, prominent below, brown tomentose below, the axils with small tufts of hairs below; tertiary veins evident, orthogonal reticulate to slightly percurrent. *Inflorescences* terminal or pseudoaxillary, sparse panicles of cymes; panicle branched to 3 degrees; main axis 1.2–2.0 cm long, the peduncle lacking; secondary axes in (2)3 ranks, the first-rank axes 2, 10–15 mm long, the second-rank axes 2, 4–10 mm long, the third-rank axes 2, 2–3 mm long; cymes branched to (1)2 degrees; bracts appearing to consist of planes of long whitish hairs, 1 mm long, immediately subtending the flowers. *Flowers* sessile to subsessile, the pedicels to 1 mm long; calyx cup-shaped, the tube 0.5–1 mm long, the lobes 5, triangular to linear, (0.5–)1–1.5 × 0.5 mm, glabrous; corolla white, the tube cylindrical, 2–3 × 1 mm, white pubescent in throat, the lobes 5, linear-ovate, 1.5–2 × 0.8 mm; stamens 5, the filaments 2 mm long in pins, 3.5 mm long in thrums, the anthers 0.5–0.7 mm long; style 3.5 mm long in pins, 2 mm long in thrums, the branches club-shaped in pins, linear in thrums, the branches puberulent. *Fruit* not seen.

Distribution (Fig. 25). Known only from the type locality near Boquete, Chiriquí, Panama, in premontane wet forest with equatorial-mountainous climate at about 1,200 m. *Psychotria boquetensis* has been collected in flower in May and June.

Additional specimens examined. PANAMA. CHIRIQUÍ: Boquete, 1,200 m, 30 June 1938 (fl), *M. Davidson 849* (A, F).

Psychotria boquetensis may be recognized first by its striking resemblance to *P. nervosa*. *Psychotria boquetensis* differs in having often linear calyx lobes usually 1–1.5 mm (vs. to 0.2 mm) long; in quantitative characters such as leaf and inflorescence size, *P. boquetensis* falls at the lower end of the *P. nervosa* spectrum.

29. Psychotria chagrensis Standley, J. Wash. Acad. Sci. 15: 105. 1925. TYPE: Panama. Canal Area: Barro Colorado Island, Gatun Lake, 17 Jan. 1924 (fr), *Standley 31373* (holotype, US). Figure 26.

Shrub 1–2.5 m tall; young stems glabrous, the bark smooth; stipules sheathing, the apex aristate and 2–4 mm long, the sheath 4–7 × 3 mm, glabrous, caducous, leaving a pale ridge. *Leaves* petiolate; petioles 2–5(–8) mm long, glabrous, flat or grooved above; blades membranous, elliptic to obovate, the apex acuminate, the base attenuate, (3–)4–7.5(–9.5) × (1–)1.5–2.5(–3.5) cm, glabrous above and below, drying red-brown, often dull green below; secondary veins (6–)8–10 pairs, diverging (45°–)55°–65°, brochidodromous with collector vein distinct, straight to slightly arcuate, scarcely elevated below, glabrous, the axils lacking domatia and hairs; tertiary veins usually inconspicuous, the intersecondaries sometimes faint, the percurrent tertiaries rarely evident. *Inflorescences* terminal or pseudoaxillary, fascicles of several flowers, 5–8 mm long, 5–8 mm across; peduncles lacking; bracts elongate, often irregularly divided, 4–5 × 1.5–2 mm, glabrous, the margins often ciliate. *Flowers* sessile; calyx green, the tube cylindrical, 0.5–2 mm long, the lobes 5, linear, 2–2.5 × 0.5 mm, glabrous to puberulent, the margins ciliate; corolla white, the tube cylindrical, 6–7 × 1 mm, white pubescent in throat, the lobes 5, narrow-elliptic, 2–2.5 × 0.7 mm; stamens 5, the filaments 5–6 mm long in pins, 8 mm long in thrums, the anthers linear, 1 mm long; style 7–9 mm long in pins, 2–5 mm long in thrums, the branches linear, sometimes recurved. *Fruit* when dry ellipsoid, 5–7 mm long, 3–3.5 mm diam., maturing red, drying deep red-brown; calyx persistent, the tube 0.5–2 mm long, the lobes 2–2.5 mm long; seed dorsal surface with 4–5 deep longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 26). Commonly collected on the Caribbean lowlands and slopes in Nicaragua–Panama, with apparently disjunct populations in Veracruz, Mexico, and Izabal, Guatemala. The range extends southward in Colombia and Peru. *Psychotria chagrensis* is found in Central America often near creek beds at elevations of 0 to 1,300 m in tropical moist to premontane moist and wet forest with equatorial to tropical-equatorial climate. It has been collected in flower in December–September, primarily March–July, and in fruit throughout the year, primarily September–December.

Selected specimens examined. MEXICO. VERACRUZ: San Andres Tuxtla, Estación de Biología Tropical Las Tuxtlas, 150 m, 7 Nov. 1968 (fr), *Martínez 1785* (A, ENCB—5 sheets, F, K, MEXU—2 sheets, MO). FIGURE 26. Distributions of *Psychotria chagrensis* (solid triangles), *P. erythrocarpa* (solid circles), *P. fosteri* (solid square), *P. jinotegensis* var. *jinotegensis* (open triangles), and *P. jinotegensis* var. *morazanensis* (open circle) in Mesoamerica.

American Hwy., 5 Oct. 1977 (fr), *Folsom et al. 5790* (MO); Cerro Campana, 8°40′N, 79°55′W, 800 m, 17 Aug. 1982 (fr), *Hamilton & D'Arcy 686* (MO); 23 July 1983 (fl), *Hamilton et al. 4043* (MO). SAN BLAS: El Llano–Cartí rd., 19.1 km from Interamerican Hwy., 9°19′N, 78°55′W, 100–350 m, 19 Sep. 1984 (fr), *Nevers et al. 3907* (MO); Cerro Habu, trail from Río Sidro, 9°23′N, 78°49′W, 420–600 m, 20 Dec. 1980 (fr), *Sytsma et al. 2769* (ENCB, MO).

Psychotria chagrensis may be recognized readily by its inflorescences consisting of fascicles of several flowers, its large (5–7 × 3–3.5 mm) fruit with conspicuously persistent calyx usually 3–4 mm long, and small leaves (usually 4–7.5 × 1.5–2.5 cm). Leaves appear at the lower end of the given size range in Costa Rica and at the higher extreme in Mexico and Guatemala.

The inserted stamens of the pin morph are longer than the inserted pistil of the thrum (5.5–6.5 vs. 2–5 mm).

30. Psychotria erythrocarpa Schlechtendahl, Linnaea 9: 385. 1834 [1835]. *Uragoga erythrocarpa* (Schldl.) Kuntze, Revis. Gen. Pl. 2: 960. 1891. TYPE: Mexico. Hda. de La Laguna (fr), *Schiede 385* (holotype, B, destroyed, photo & fragment, F neg. no. 519; isotype, K). Figures 2c, 7c, 26.

Mapouria chamissoana Loesener, Verh. Bot. Vereins Prov. Brandenburg 65: 112. 1923. *Psychotria chamissoana* (Loes.) Standl., J. Wash. Acad. Sci. 17: 341. 1927. TYPE: Mexico. Tecolute, Jan. (fr), *Scheide 1266* (holotype, B, destroyed, photo, F neg. no. 446).

Shrub 1–3 m; young stems pale brown to red-brown tomentose or sometimes glabrous, the bark gray, furrowed longitudinally; stipules linear, 8–12 × 1.5–2 mm, glabrous to sparsely tomentose, caducous, leaving a pale ridge with long red-brown fringe to 1 mm long (Fig. 2c). *Leaves* subsessile to petiolate; petioles to 10 mm long, pale tomentose, flat and grooved above; blades membranous, obovate to sometimes elliptic, the apex acute to obtuse to rounded, the base attenuate, (3.5–)5–8(–10) × (1–)1.5–3.5(–5) cm, sparsely pale tomentose to glabrous above, densely tomentose especially near margins to glabrous below, drying green-brown above, paler green below; secondary veins 6–8(–9) pairs, diverging 35°–50°, eucamptodromous to brochidodromous, straight to arcuate near margin, elevated below, dense pale tomentose to glabrous below, the axils sometimes with tufts of pale hair below; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes or glomerules (Fig. 7c); panicle branched to 3–4 degrees; main axis (1.2–)2.5–5.5 cm long, the peduncle (0.5–)1.5–3 cm long; secondary axes in (2–)3

ranks, the first-rank axes 2, (0.4–)0.8–2 cm long, the second-rank axes 2, (0.2–)0.3–1 cm long, the third-rank axes 2, 0.1–0.3 cm long; cymes branched to 1–2 degrees; bracts triangular, 1.5 × 1 mm. *Flowers* sessile to pedicellate, the pedicels to 1 mm long; calyx cup-shaped, the tube 0.5–1 mm long, the lobes 5, barely evident, red-brown tomentose; corolla white, the tube cylindrical to slightly campanulate, 2–2.5 × 1–1.5 mm, white pubescent in throat, the lobes 5, narrow-triangular, 1.5–2 × 1 mm; stamens 5, the filaments 2–2.5 mm long in pins, 3–3.5 mm long in thrums, the anthers 0.5–0.8 mm long; style 3.5–4 mm long in pins, 2–2.5 mm long in thrums, the branches linear in pins and club-shaped in thrums. *Fruit* ellipsoid when dry, 4.5–6 mm long, 3–4.5 mm diam., maturing red, drying brown, glabrous to pale puberulent when dry; calyx persistent as a beak to 0.5 mm long; seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 very deep longitudinal furrows.

Distribution (Fig. 26). Commonly collected in Mexico (primarily Veracruz and Chiapas) and upland Guatemala, and extending to Cayo, Belize, in areas of subevergreen forest with usually tropical-mountainous or sometimes equatorial to subtropical-tropical climate. *Psychotria erythrocarpa* ranges in elevation 0–2,000 m, lower in Veracruz and higher in Chiapas and Guatemala. It has been collected in flower throughout the year, primarily April–July, and in fruit throughout the year, primarily August–January.

A minority of glabrous individuals appear in many populations of *Psychotria erythrocarpa* (D. Lorence, pers. comm.), so *P. chamissoana*, defined by its glabrous aspect, is included within *P. erythrocarpa*.

Psychotria erythrocarpa may be recognized by its usually pale brown to red-brown tomentose aspect, obovate leaves with few (usually 6–8) secondary veins diverging acutely (35°–50°), and small (usually 2.5–5.5 cm long) inflorescences with secondary axes two per rank in three ranks. The fruits occupy the small end of the spectrum in Veracruz and the large end in Chiapas and southward.

31. Psychotria fosteri C. Hamilton, Phytologia 64: 224. 1988. TYPE: Panama. Veraguas: Playa Rosario, northern tip of Coiba Island, 26 Aug. 1970 (fl, fr), *Foster 1605* (holotype, DUKE; isotypes, F, GH, MO). Figure 26.

Shrub ca. 1 m high; young stems glabrous, the bark slightly furrowed longitudinally; stipules sheathing, narrow, with 2 triangular lobes, the sheath 8–12 × 1–3 mm, the lobes 2–3 mm long, fringed, with darker red-brown midrib leading to apex of each lobe, caducous, leaving a red-brown ridge with irregular fringe. *Leaves* petiolate; petioles 5–10 mm, glabrous, flat above; blades membranous, elliptic-obovate, the apex acuminate to mucronate, the base attenuate, (6–)8–12 × (2–)3–5 cm, glabrous above and below, drying green-brown above, deep red-brown below; secondary veins 11–14 pairs, diverging 70°–80°, brochidodromous often with collector vein distinct, slightly arcuate, prominulous below, glabrous, drying deeper red-brown than blade, the axils lacking domatia or hairs; tertiary veins inconspicuous, reticulate. *Inflorescences* terminal, fascicles of several flowers, ca. 8 mm long, 10 mm across; peduncles lacking; bracts broadly triangular, irregularly cleft, ca. 5 × ca. 5 mm, fringed. *Flowers* sessile; calyx cup-shaped, the tube 1.5 mm long, the lobes 5, triangular, 0.5–1 × 0.5 mm, slightly fringed; corolla white, the tube cylindrical, 3.5 × 0.8 mm, white pubescent in throat, the lobes 5, triangular, 2 × 0.7 mm; stamens 5, the filaments 3 mm long in pins, not seen in thrums, the anthers 0.5 mm long; style 4–4.5 mm long in pins, not seen in thrums, the branches linear. *Fruit* when dry ellipsoid, 5–6 mm long, 2.5–3 mm diam., maturing orange (probably to red), drying dark red-brown; calyx persistent, the tube 1–1.5 mm long, the lobes ca. 1 mm long; seed dorsal surface with 5 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 26). Known only from the type collection from Coiba Island, Panama, in tropical moist forest with tropical-equatorial climate. It was collected in flower and fruit on August 26.

Psychotria fosteri may be recognized as a magnified version of *P. chagrensis*, having an inflorescence consisting of a fascicle of flowers and fruit ellipsoid with a conspicuous persistent calyx. *Psychotria fosteri* differs in having larger (sheath 8–12 vs. 4–7 mm long) biaristate (vs. aristate) stipules, larger mature leaves (usually 8–12 × 3–5 vs. 4–7.5 × 1.5–2.5 cm), shorter calyx lobes (0.5–1 vs. 2–2.5 mm), and much shorter corolla tubes (3.5 vs. 6–7 mm).

The lone flowering collection is a pin morph.

32. Psychotria fruticetorum Standley, J. Arnold Arbor. 11: 42. 1930. TYPE: Honduras. Comayagua: vic. Siguatepéque, 1,080–1,400 m, 14–27 Feb. 1928 (fr), *Standley 56197* (holotype, F; isotype, A). Figure 25.

Shrub, 0.5–3 m tall; young stems glabrous, the bark red-brown or pale, smooth; stipules sheathing, biaristate with extensions arising from apical corners of sheath, 1.5–2 × 1.5–2 mm, glabrous,

caducous, leaving a pale or red-brown ridge with or without fringe. *Leaves* petiolate; petioles 2–5 mm long, glabrous, flat above; blades membranous to subcoriaceous, elliptic to slightly obovate, the apex acute to acuminate, the base narrowly cuneate to attenuate, the margin often inrolled, (3–)5–7(–9) × (1–)2–4(–4.5) cm, glabrous above and below, drying chalky yellow-green to red-brown; secondary veins (4–)5–7(–8) pairs, diverging 55°–65°, eucamptodromous, straight then constantly arcuate toward margin, barely elevated below, glabrous, the axils often with minute tufts of white hairs below; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3 degrees; main axis 1.5–4.5 cm long, the peduncle 0.3–2.5 cm long or rarely lacking; secondary axes in (2–)3–4(–5) ranks, the first-rank axes 2 or 4, the longer pair 0.5–1.8 cm long, the shorter pair when present 0.5 cm long, the second-rank axes 2, 0.1–1.1 cm long, the third-rank axes 2(4), the longer pair 0.2–0.7 cm long, the shorter pair when present 0.2 cm long, the fourth-rank axes 2, 0.4–0.5 cm long, the fifth-rank axes 2, 0.3 cm long; cymes branched to 2 degrees; bracts broad, irregular, to 1 mm long, glabrous to puberulent, often minutely fringed. *Flowers* on pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular to barely evident, to 0.5 × 0.5 mm, often minutely fringed; corolla white, the tube cylindrical, 2 × 1.5 mm, white pubescent in throat, the lobes 5, linear, 1.5–2 × 1 mm; stamens 5, the filaments 1.5–2 mm long in pins, 3–3.5 mm long in thrums, the anthers 0.8 mm long; style 3.5–5 mm long in pins, 2.5 mm long in thrums, the branches short, linear, often recurved. *Fruit* when dry ellipsoid, 4–5 mm long, 3–3.5 mm diam., maturing red, drying red-brown; persistent calyx to 0.5 mm long; seed dorsal surface with 4 deep longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 25). Widespread from Mexico through Panama, mostly on the Caribbean side, with greatest concentration in Belize and eastern Petén, Guatemala, in tropical to premontane moist forest with equatorial to tropical climate. *Psychotria fruticetorum* ranges in elevation 0–2,000 m, reaching over 1,300 m only in Mexico and parts of Guatemala. It has been collected in flower throughout the year, primarily March–July, and in fruit throughout the year.

SAN BLAS: mainland opposite Isla Mosquito (Kwitupu), 19 Oct. 1966 (fr), *Duke 8989* (MO—2 sheets).

Psychotria fruticetorum may be recognized by its small leaves (usually 5–7 × 2–4 cm) drying chalky yellow-green to red-brown with barely elevated secondary veins and inconspicuous tertiaries, its small inflorescences (1.5–4.5 cm long) with secondary axes usually 2 per rank in 3–4 ranks, and small (4–5 × 3–3.5 mm) ellipsoid fruit. Mexican collections differ from those from the rest of the range in having generally smaller leaves, 5 vs. 6–7(8) secondary veins, and a higher fruit length-to-diameter ratio.

The exserted pistil of the pin morph is often longer than the exserted stamens of the thrum (3.5–5 vs. 3.5–4 mm).

33. Psychotria jinotegensis Nelson, Molina & Standley, Phytologia 50: 1. 1981. TYPE: Nicaragua. Jinotega: region of La Montañita and Las Mesitas, in sierra W of Jinotega, ca. 1,100–1,400 m, 29 June 1947 (fl), *Standley 10314* (holotype, EAP, n.v.; isotype, F, n.v.). Figures 9d, 26.

Shrub (0.5–)1–4(–6) m tall; young stems ferrugineous-pubescent or very sparsely tomentose, the bark smooth; stipules sheathing, ovate to linear, 15–23 × 4–6 mm, usually ferrugineous-pubescent, caducous, leaving a pale ridge with dark red-brown fringe. *Leaves* petiolate; petioles 0.5–1.5 cm long, pubescent or glabrous, flat above; blades membranous, elliptic to oblanceolate, the apex acute or sometimes acuminate, the base attenuate, (7–)9–14(–15.5) × (2–)2.5–4.5(–5.5) cm, pale tomentose or glabrous above, densely pubescent or glabrous below, drying gray-green to red-brown; secondary veins 9–14 pairs, diverging 40°–50°, eucamptodromous to brochidodromous, straight then arcuate near margin, elevated below, pubescent or glabrous below, the axils with tufts of hairs below; tertiary veins evident, orthogonal reticulate to slightly percurrent. *Inflorescences* terminal or pseudoaxillary, few-branched panicles of condensed cymes; panicle branched to 3–4 degrees; main axis (2.5–)4–6.5 cm long, the peduncle lacking or to 1(–3) cm long; secondary axes in (2–)3 ranks, the first-rank axes 1–2, (1–)1.5–5 cm long, the second-rank axes 2, 0.5–2.5 cm long, the third-rank axes 2(4), the longer pair 0.2–0.8 cm long, the shorter pair when present 0.1 cm long; cymes branched to (1)2 degrees; bracts and bracteoles

linear, 1.5–3 mm long; usually ferrugineous-pubescent. *Flowers* sessile or on pedicels to 1.5 mm long; calyx cup-shaped, the tube cylindrical, 0.5–1 mm long, the lobes 5–6, triangular, 0.5–1 × 0.7 mm, puberulent; corolla white, the tube cylindrical to campanulate, 3.5–4 × 1.5–2 mm, white pubescent in throat, the lobes 5–6, 1.5–2.5 × 1.2 mm; stamens 5–6, the filaments 3 mm long in pins, 5–5.5 mm long in thrums, the anthers 1 mm long; style 5 mm long in pins, 3–4 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid, (5–) 5.5–6.5 mm long, 4–5 mm diam., maturing red, drying red-brown, ferrugineous-pubescent or glabrous; persistent calyx conspicuous, 1–3 mm long (Fig. 9d); seed dorsal surface with 6–8 irregular longitudinal furrows, the ventral surface with 2 deep regular plus several irregular longitudinal furrows.

Distribution (Fig. 26). Known from southeastern Guatemala through northwestern Nicaragua in tropical moist forest with tropical to tropical-mountainous climate.

Psychotria jinotegensis may be recognized by its usually ferrugineous aspect, elliptic to oblanceolate leaves with secondary veins diverging 40°–50°, and ellipsoid fruit with conspicuous (1–3 mm long) persistent calyx tube.

KEY TO THE VARIETIES OF *PSYCHOTRIA JINOTEGENSIS*

1a. Ferrugineous-pubescent and/or tomentose on young stems, both leaf surfaces, and on dry fruit; secondary vein axils with tufts of reddish hairs ..... 30a. var. *jinotegensis*
1b. Generally glabrous or only sparsely tomentose; secondary vein axils with tufts of white hairs ..... 30b. var. *morazanensis*

33a. Psychotria jinotegensis Nelson, Molina & Standley var. **jinotegensis.** Figure 26.

Shrub; young stems ferrugineous-pubescent. *Leaves:* petioles ferrugineous-pubescent; blades pale tomentose above, densely ferrugineous-pubescent below, drying green-brown to deep red-brown; secondary veins (9–)10–14 pairs, ferrugineous-pubescent, the axils with tufts of reddish hairs below. *Fruit* when dry ferrugineous-pubescent.

Distribution (Fig. 26). Known from southeastern Guatemala eastward across southern Honduras and northern El Salvador to northwestern Nicaragua at elevations of 1,000–2,000 m. It has been collected in flower June–July and December–February and in fruit August–February.

Selected specimens examined. GUATEMALA. BAJA VERAPAZ: Unión Barrios, 27 Feb. 1972 (fr), *Contrereas 11062* (MO); along hwy. to Cobán, ca. 1.5 km S of turnoff to Salamá, pine forest, 1,300 m, 16 July 1977 (early fr), *Croat 41138* (MO); nr. DISTRITO CENTRAL: 2.5 km N of Zambrano along rd. to San Francisco de Soroguara, 1,370 m, 1 July 1970 (fl), *Davidse & Pohl 2245* (F, MO, NY); nr. Zambrano, 26 Sep. 1969 (fr), *Lauvert & Barkley 39552* (MO, TEFH); San Matías NO de Tegucigalpa, 1,400 m, 25 Sep. 1983 (fr), *Paredes 97* (TEFH). EL PARAISO: drainage of Río Yeguare, márgenes del Río Lizapa entre Guinope y Las Casitas, 1,300 m, 1 Nov. 1950 (fr), *A. Molina R. 3357* (MO); Francisco Morazán, Cerro Canta Gallo, 14 km NE de Tegucigalpa, 1,046 m, 2 Oct. 1983 (fr), *M. Castro M. 83* (TEFH); along Río Rancho Quemado, S of Tegucigalpa, km 20–25 on rd. to Sabana Grande, 1,300 m, 9 Nov. 1966 (fr), *A. Molina R. 18648* (GH, NY). INTIBUCÁ: 2 km de La Esperanza, orillas de La Pozona, 28 June 1974 (fl), *J. Martínez & Bejarano 236* (TEFH). EL SALVADOR. CHALATENANGO: S del Río Nomiapa, La Palma, 1,100 m, 6 July 1976 (early fr), *Montalvo 4695* (MO). NICARAGUA. JINOTEGA: sierra W of Jinotega, trail to Cerro de la Cruz, 1,050–1,350 m, 27 June 1947 (fl), *Standley 10214* (F).

33b. Psychotria jinotegensis Nelson, Molina & Standley var. **morazanensis** C. Hamilton, Phytologia 64: 226. 1988. TYPE: El Salvador. Morazán: easternmost peak, Montes de Cacaguatique, nr. summit on N side, 13°46′N, 88°13′W, 1,500 m, 25 Dec. 1941 (fr), *Tucker 610* (holotype, US: isotypes, F, K, NY). Figure 26.

Shrub; young stems very sparsely tomentose. *Leaves:* petioles glabrous; blades glabrous above and below, drying gray-green to pale red-brown; secondary veins 9–11 pairs, glabrous, the axils with tufts of whitish hairs below. *Fruit* glabrous when dry.

Distribution (Fig. 26). Known only from the type collection from eastern El Salvador, at ca. 1,500 m. This variety was collected in fruit December 25.

34. Psychotria mirandae C. Hamilton, Phytologia 64: 229. 1988. TYPE: Mexico. Chiapas: Berriozábal a Las Vistas, 17 July 1949 (fl), *Miranda 5395* (holotype, US; isotype, MEXU). Figure 27.

Shrub ca. 1 m tall; young stems red-brown tomentose, the bark pale, smooth; stipules sheath-

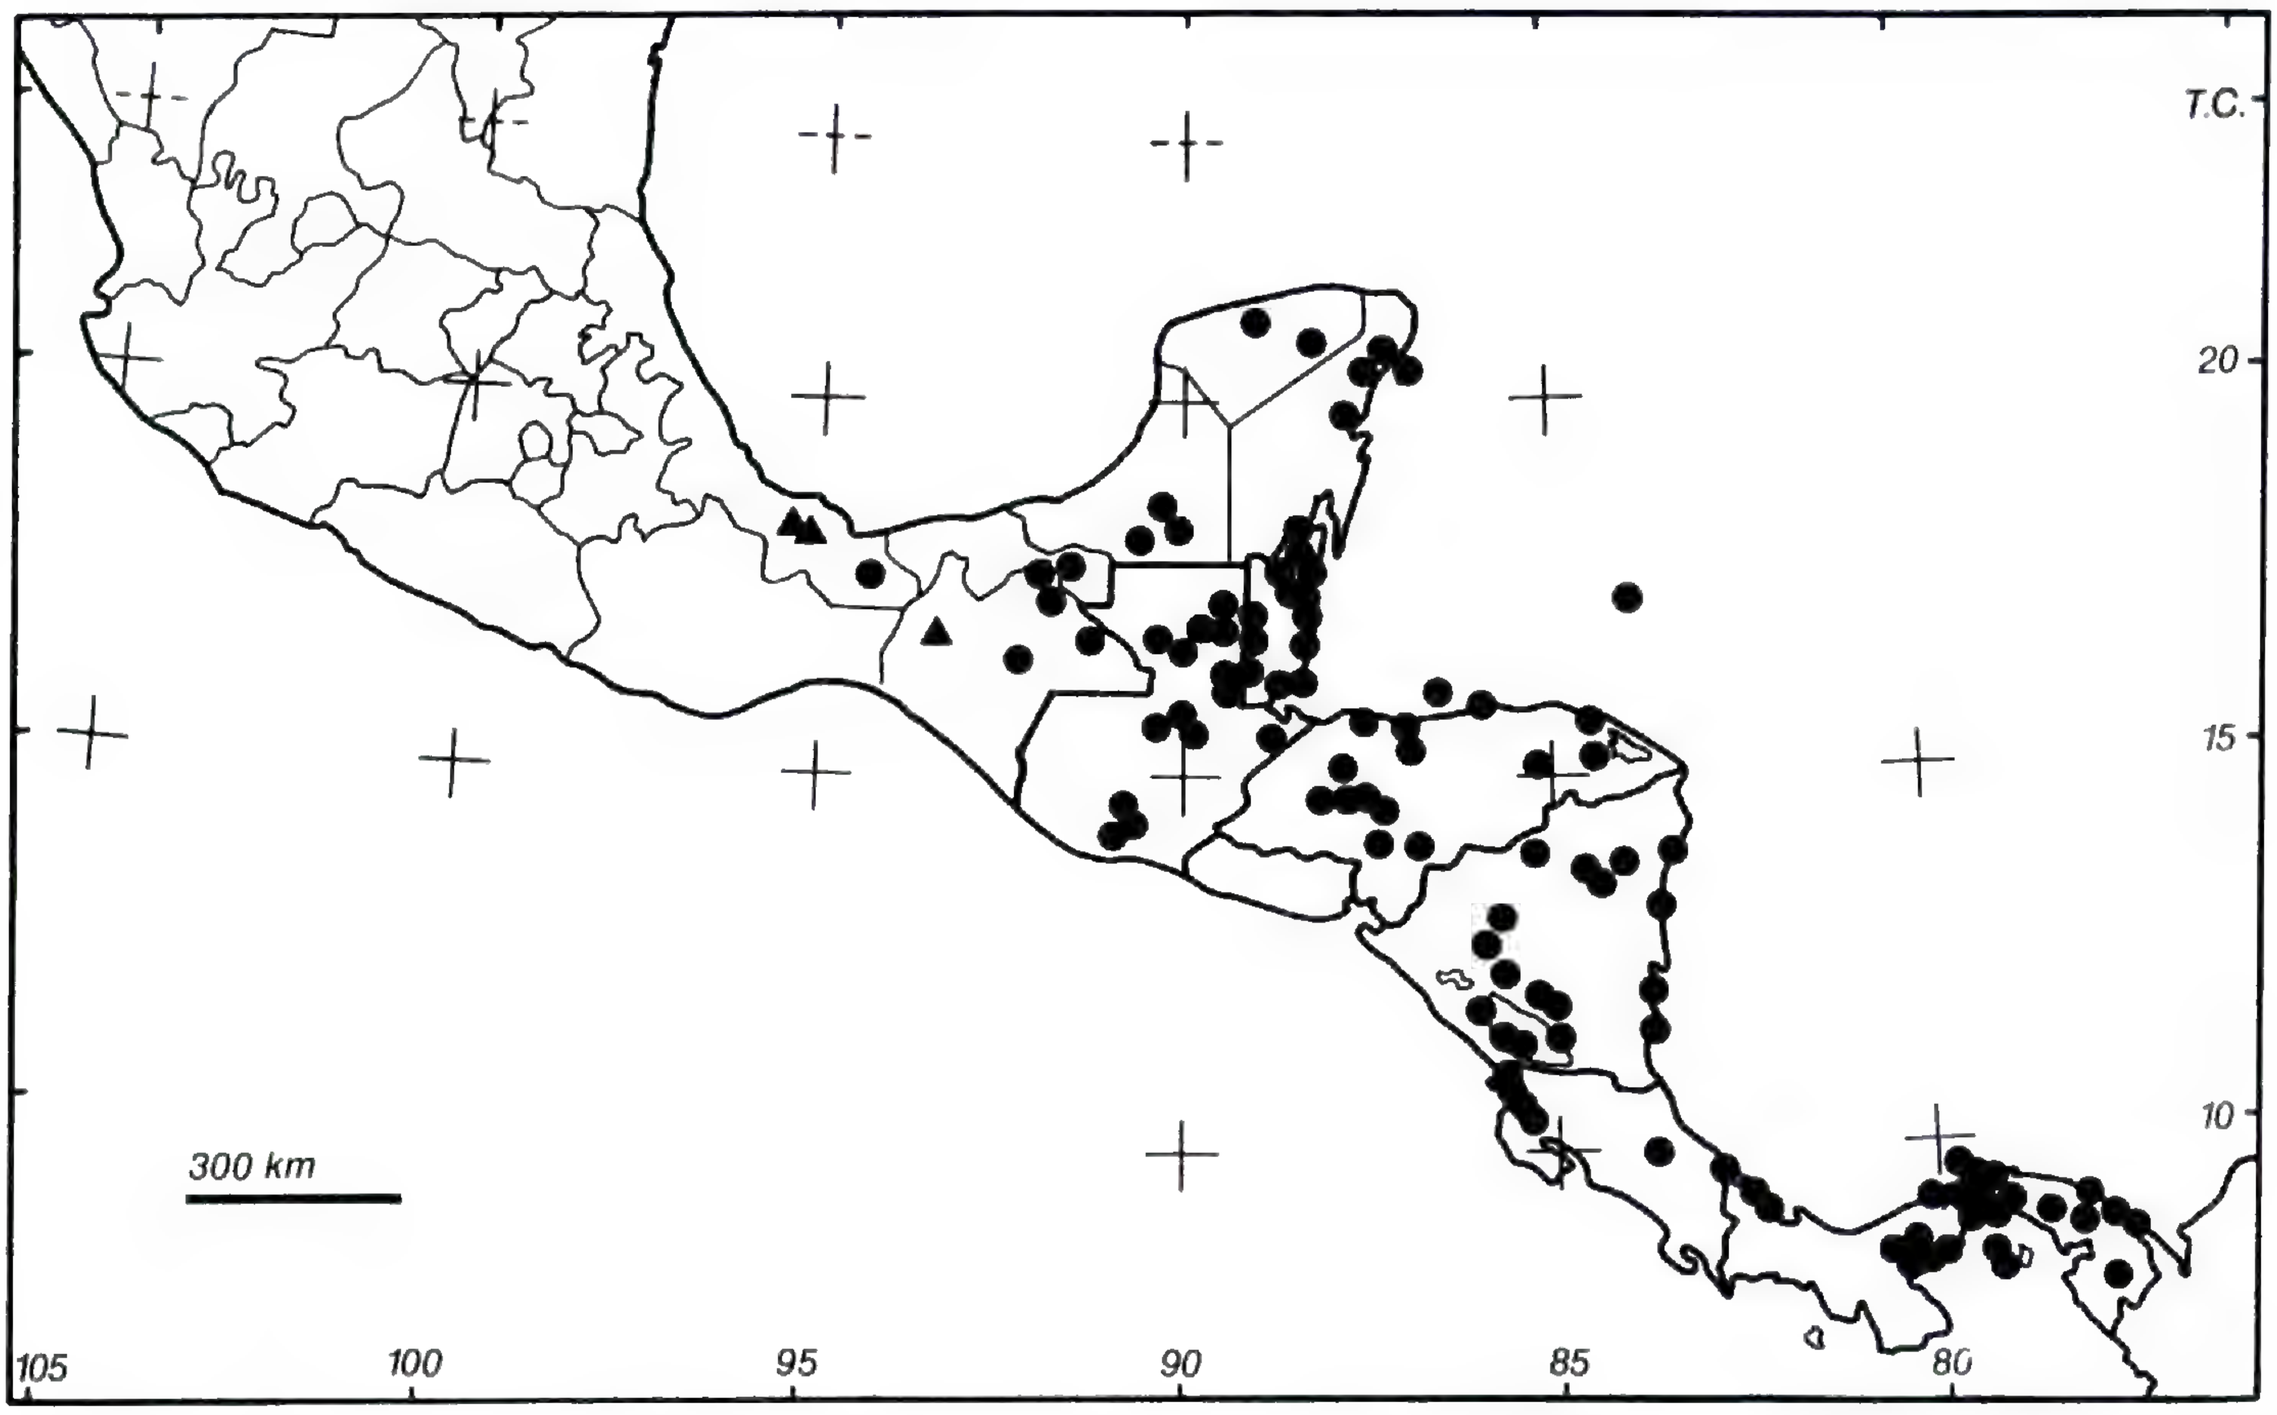

FIGURE 27. Distributions of *Psychotria mirandae* (triangles) and *P. nervosa* (circles) in Mesoamerica.

ing, rounded at apex, 4–8 × 3–4 mm, red-brown tomentose outside, caducous, leaving a pale ridge. *Leaves* subsessile to petiolate; petioles 1–4 mm long, red-brown tomentose, furrowed above; blades membranous, narrowly obovate, the apex caudate, the base attenuate, 6–12 × 2–4 cm, glabrous above and below, drying dull red-brown; secondary veins 7–10 pairs, diverging 48°–55°, eucamptodromous, slightly arcuate, prominent below, red-brown sparsely tomentose below, the axils with small tufts of hair below; tertiary veins evident, reticulate to slightly percurrent. *Inflorescences* terminal, fascicles of flowers or with several short axes, 1–1.5 cm long, 1–2.5 cm across; peduncle lacking; bracts triangular, 0.5 × 0.5 mm, glabrous to sparsely tomentose. *Flowers* subsessile, the pedicels 1–2 mm long; calyx cylindrical, the tube 2–2.5 mm long, the lobes 5, linear, 2–3 × 1.2 mm, sparsely ciliate on margin; corolla white(?), the tube cylindrical, 3 × 1 mm, white pubescent in throat, the lobes 5, linear, 1.5–2 × 0.5 mm; stamens 5, the filaments not seen in pins, 4 mm long in thrums, the anthers 0.8 mm long; style not seen in pins, 2.5–3 mm long in thrums, the branches club-shaped. *Fruit* ellipsoid when dry, 5–7 mm long, 4–5 mm diam., maturing red, drying red-brown, red-brown tomentose; calyx persistent, the tube 2–2.5 mm long, the lobes ca. 2 mm long; seed dorsal surface with 5 longitudinal furrows, the ventral surface with 2 longitudinal furrows.

Distribution (Fig. 27). Limited to eastern Veracruz and northwestern Chiapas, Mexico, at 700–1,000 m elevation in evergreen forest with equatorial-tropical to tropical climate. It has been collected in flower in March and May–July and in fruit in August and December.

Additional specimens examined. MEXICO. CHIAPAS: Mpio. Berriozábal, 13 km N of Berriozábal nr. Pozo Turipache and Finca El Suspiro, 900 m, 15 May 1973 (fl), *Breedlove 35316* (MEXU); Cerro de San Martín, Mar. 1845 (fl), *Galeotti 2684* (F—3 sheets, US); Berriozábal a Las Vistas, 4 Dec. 1949 (fr), *Miranda 5834* (MEXU, US); San Fernando, Predio del Rosario, 21 June 1951 (fl), *Miranda 7216* (MEXU). VERACRUZ: Mpio. Catemaco, cerro entre Zapoapan y San Juan Seco al SW de Lago Catemaco, 700 m, 7 June 1972 (fl), *Beaman 6094* (F, MEXU—2 sheets); region of San Andrés Tuxtla, nr. Zapoapan, SE of Catemaco, 17 Aug. 1953 (fr), *Dressler & Jones 93* (GH, NY, US); Catemaco, 25 Mar. 1956 (fl), *Paray 1946* (ENCB); km 156.5 of Veracruz–Coatzacoalcos rd., 13 July 1974 (fl), *Sohmer 9409* (MEXU).

Psychotria mirandae may be recognized first by its marked resemblance to *P. nervosa* and second by its contracted (sometimes contracted to fascicles of flowers) inflorescences and wider (4–5 mm vs. 2.5–3 mm diam. in *P. nervosa*) fruit with persistent calyx having a conspicuous tube and lobes ca. 4 mm long.

The seven flowering collections examined are all of the thrum morph, which suggests strongly that the species is thrum-monomorphic.

35. Psychotria nervosa Swartz, Prodr., 43. 1788. TYPE: Jamaica. (fl), *Swartz s.n.* (holotype, S, n.v., photo, A). Cf. also Swartz, Fl. Ind. Occid., 403. 1797. Figure 27.

Psychotria elongata Bentham in Oersted, Vidensk. Meddel. Dansk Naturhist. Foren. Kjøbenhavn 1852: 32. 1853. TYPE: Nicaragua. Granada: Volcán Mombacho, June 1846 (early fr), *Oersted 11594* (holotype, C, n.v., photo, F neg. 22829, photo & fragment, US).

Psychotria quiinifolia Dwyer, Ann. Missouri Bot. Gard. 53: 108. 1966. TYPE: Panama. Bocas del Toro: Almirante, Changuinola Canal, (fl), *Blum 1402* (holotype, MO).

Shrub 0.5–2(–3) m tall; young stems ferrugineous-tomentose to sometimes glabrous, the bark smooth; stipules sheathing, rounded-ovate, sometimes short-acuminate, 6–11 × 3–6 mm, ferrugineous-pubescent to glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.3–1.2(–2.5) cm long, ferrugineous-pubescent to glabrous, grooved above; blades membranous, oblanceolate to rarely elliptic, the apex long-acuminate, the base attenuate, (6–)11–17(–18) × (2–)4–6.5(–7.5) cm, sparsely tomentose to sometimes glabrous above and below, usually denser below, the midvein usually ferrugineous-pubescent, the margin often red-brown ciliate, drying pale red-brown to green-brown, the veins usually drying reddish; secondary veins (10–)12–17 pairs, diverging 55°–65°, eucamptodromous to brochidodromous, increasingly arcuate toward margin, elevated below, sparsely ferrugineous-pubescent, the axils lacking domatia or hairs or rarely with fascicles of several red-brown hairs; tertiary veins inconspicuous to evident, orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, panicles of cymes, the cymes often contracted; panicle branched to 3 degrees; main axis 1–4(–5) cm long, the peduncle lacking; secondary axes in 3(4) ranks, the first-rank axes 2(4), equal, 0.8–2.5(–4) cm long, the second-rank axes (1)2(3), equal, 0.6–1.5 cm long, the third-rank axes 2, equal, 0.2–0.7 cm long, the fourth-rank axes 2, equal, 0.2 cm long; cymes branched to 2–3 degrees; bracts and bracteoles triangular, inconspicuous, to 0.5 mm long, ferrugineous-pubescent. *Flowers* sessile to subpedicellate, the pedicels to 0.5 mm long; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 5, triangular to not evident, to 0.2 mm long, puberulent; corolla white, the tube cylindrical, 2–3 × 1 mm, white pubescent in throat, often puberulent without, the lobes 5, lanceolate, 1.5 × 0.8 mm; stamens 5, the filaments 1.5–2.5 mm long in pins, 3.5–5 mm long in thrums, the anthers 0.7–1 mm long; style 4–5 mm long in pins, 2–2.5 mm long in thrums, the branches short, clublike. *Fruit* narrow ellipsoid, 5.5–7 mm long, 2.5–3 mm diam., maturing red, drying red-brown, usually red-brown puberulent; persistent calyx inconspicuous or a minute beak; seed dorsal surface with 4–5 longitudinal furrows, the ventral surface with 2 sometimes incompletely divided longitudinal furrows.

Distribution (Fig. 27). Ubiquitous, from southern Mexico and the Yucatán peninsula through Panama, most common on the Caribbean coast, at 0–1,200 m elevation in tropical moist to premontane moist to sometimes tropical dry forest with equatorial to tropical (usually equatorial-tropical) climate. It occurs also in Florida, the Bahamas, throughout the Greater and Lesser Antilles, Colombia, and Venezuela. It has been collected in flower throughout the year, primarily February–June in Mexico–Costa Rica and throughout the year in Panama, and in fruit throughout the year.

All the species in synonymy have been properly synonymized before, with the exception of *P. quiinifolia*, the morphology of which does not differ from that of *P. nervosa*. Degree of pubescence varies within populations, and infraspecific taxonomy based on this character (e.g., subsp. *rufescens*) is not recognized.

Psychotria nervosa may be recognized by its usually reddish pubescent aspect, leaves with usually eucamptodromous secondary veins diverging 55°–65°, small (1–4(–5) cm long) inflorescences lacking peduncles and with secondary axes usually 2 per rank in usually 3 ranks, and narrow-ellipsoidal fruit (5.5–7 × 2.5–3 mm). There appears to be no geographic component to the variation between glabrous and densely tomentose aspect. Collections from Florida are noteworthy for small leaves and relatively large inflorescences.

GROUP 6. THE *PANAMENSIS* GROUP

Shrub or tree; *young stems glabrous or* (*often red-brown*) *puberulent*; stipules usually sheathing, lanceolate (Fig. 2d) or ovate, or less commonly linear or triangular with the apex sometimes bilobed or biacuminate, uniform in color, glabrous or fringed or puberulent, caducous. *Leaf* blades usually elliptic, or sometimes obovate, ovate, or lanceolate, drying green-brown to red-brown to brown, sometimes paler below; secondary veins (4–)6–19(–22) pairs, diverging (30°–)45°–75°(–80°), *eucamptodromous to brochidodromous*, the axils sometimes with domatia (sometimes *P. cocosensis* and *P. lundellii*) or with tufts of hair (sometimes *P. chiriquina*, *P. lundellii*, and *P. mexiae*) or usually lacking; tertiary veins orthogonal reticulate to percurrent. *Inflorescences* panicles of cymes (or of glomerules sometimes in *P. panamensis* or of individual flowers in *P. hornitensis*), *nonpeduncu-late* (Fig. 7e) except in *P. olgae*, *P. stockwellii*, and sometimes in *P. cascajalensis*, *P. chiriquina*, *P. dwyeri*, *P. lundellii*, *P. panamensis*, *P. sarapiquensis*, and *P. trichotoma*; *secondary axes usually in 1 pair per rank* or less commonly 2 equal pairs or 2 size-differentiated pairs per rank, *diverging acutely except in P. stockwellii*; bracts not conspicuously enlarged, to 3 mm long only in *P. chiriquina*. *Corolla* tubes (1.5–)2–5 mm long, the lobes without apical extensions. *Fruit* ellipsoid, obovoid, or spherical when dry; *persistent calyx a beak* or less commonly a conspicuous tube (*P. cocosensis* [Fig. 9c] and *P. olgae* and sometimes *P. panamensis*) *or often not evident*; *seed dorsal surface with (3–) 4–10 often irregular longitudinal furrows*, the ventral surface with 2 deep plus often several irregular longitudinal furrows (Figs. 10g, 10h).

Half of the 12 species of the group are assigned to the *Psychotria panamensis* complex; *P. pana-*

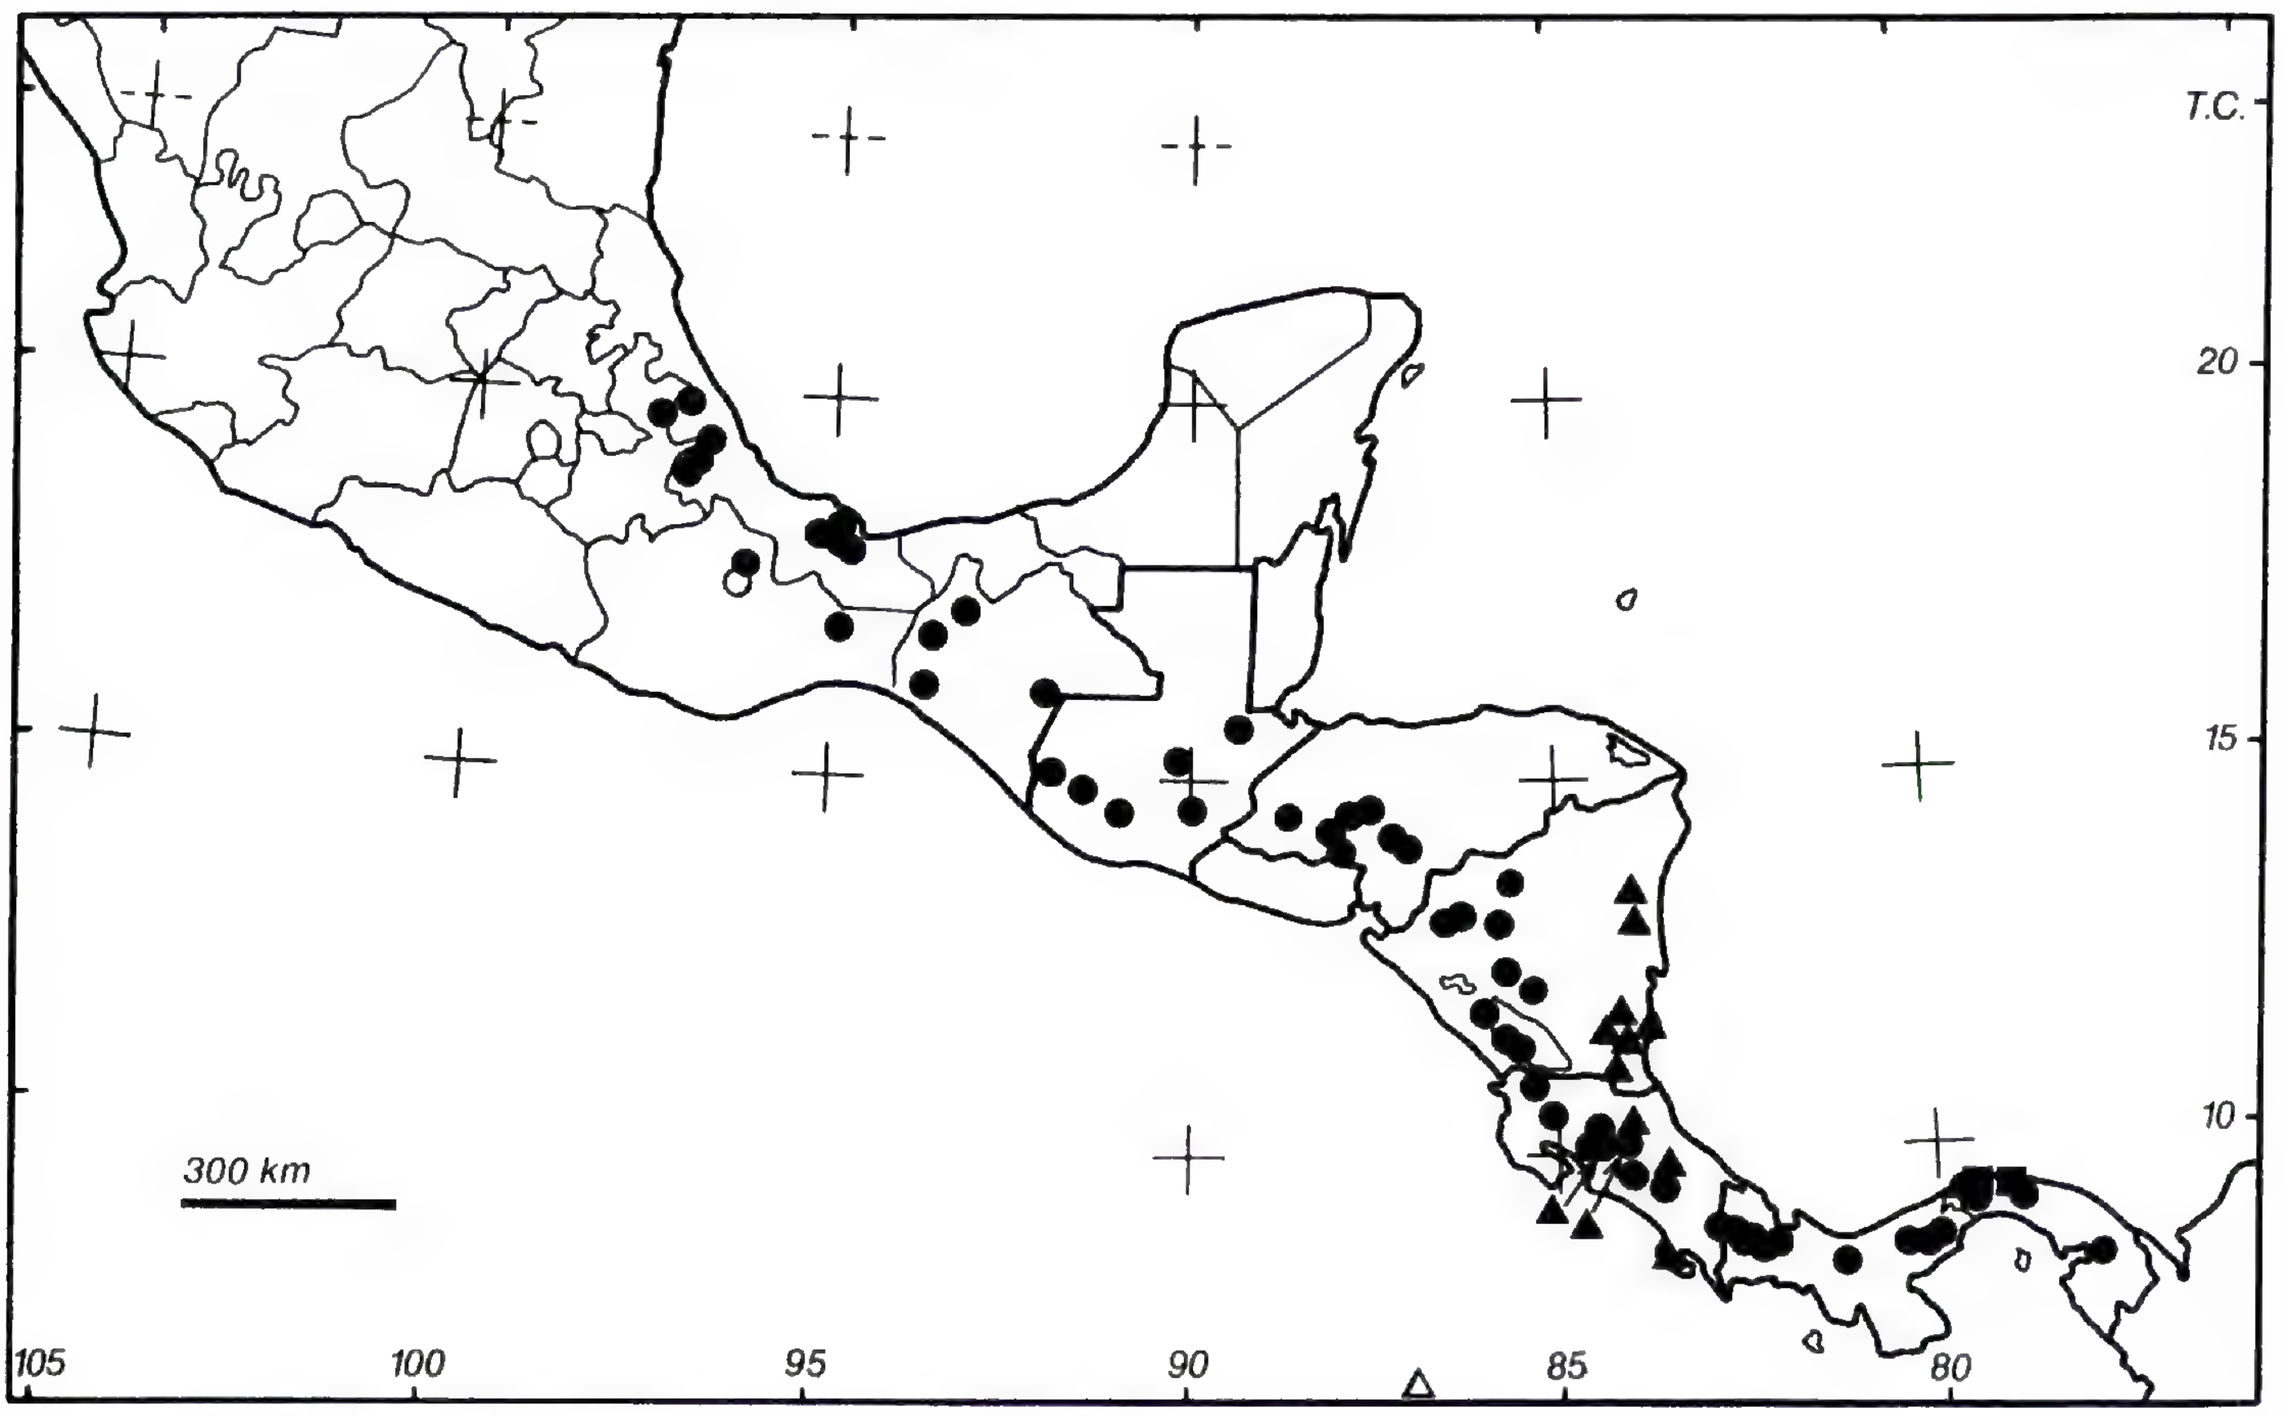

FIGURE 28. Distributions of *Psychotria cocosensis* (open triangle), *P. panamensis* var. *compressicaulis* (solid triangles), *P. panamensis* var. *ixtlanensis* (open circle), *P. panamensis* var. *magna* (solid squares), and *P. panamensis* var. *panamensis* (solid circles) in Mesoamerica.

mensis is widespread (Fig. 28), the other five much less so: *P. cascajalensis* (Coclé, Panama; Fig. 29), *P. cocosensis* (Cocos Island, Costa Rica; Fig. 28), *P. dwyeri* (southern Mexico; Fig. 29), *P. olgae* (eastern Panamá Province; Fig. 29), and *P. stockwellii* (Costa Rica and Panama; Fig. 30). Three other widespread species have character states that distinguish them from typical members of the group and are of uncertain affinities, although analysis might reveal they belong in the *panamensis* complex: *P. trichotoma* has obovoid fruits and conspicuously brochidodromous venation; *P. sarapiquensis* has usually narrowly oblanceolate leaves; and *P. mexiae* has 5–8 deep irregular furrows on the seed dorsal surface. The most cohesive complex is that of *P. chiriquina*, which includes that species (Nicaragua through Panama; Fig. 29), *P. lundellii* (Chiapas through El Salvador; Fig. 29), and *P. hornitensis* (western Panama; Fig. 30); they share ovate stipules and shallow furrows on the seed ventral surface.

Of the 15 taxa in the group, eight appear distylous; of those, *Psychotria dwyeri*, *P. mexiae*, *P. olgae*, *P. stockwellii*, and *P. trichotoma* show some between-morph asymmetry in floral part lengths. *Psychotria lundellii* appears to be pin-monomorphic in Belize, but recently I examined a thrum collection from Guatemala. *Psychotria panamensis* var. *compressicaulis*, on the other hand, is thrum-monomorphic. *Psychotria cocosensis* and *P. hornitensis* are long-homostylous. *Psychotria cascajalensis*, *P. panamensis* var. *ixtlanensis*, and *P. panamensis* var. *magna* do not have sufficient flowering material for analysis.

36. Psychotria cascajalensis C. Hamilton, Phytologia 64: 220. 1988. TYPE: Panama. Coclé: N of Penonomé, between Llano Grande and Cascajal, rd. to Coclesito, 480 m, 2 May 1979 (fl), *Hammel 7227* (holotype, MO-2901097; isotypes, ENCB, MO). Figure 29.

Tree 10 m tall; young stems glabrous to sparsely puberulent, the bark smooth; stipules oval, rounded, 6–7 × 3–3.5 mm, fringed, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 2–4 mm long, glabrous, flat above; blades coriaceous, elliptic, the apex acute, the base attenuate, 3.5–6(–7) × (1.5–)2–2.7 cm, glabrous above and below, drying dull red-brown to green-brown; secondary veins 4–6 pairs, diverging 55°–65°, brochidodromous with secondary loops inconspicuous, straight then arcuate near margin, not elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous. *Inflorescences* terminal, panicles of cymes or glomerules;

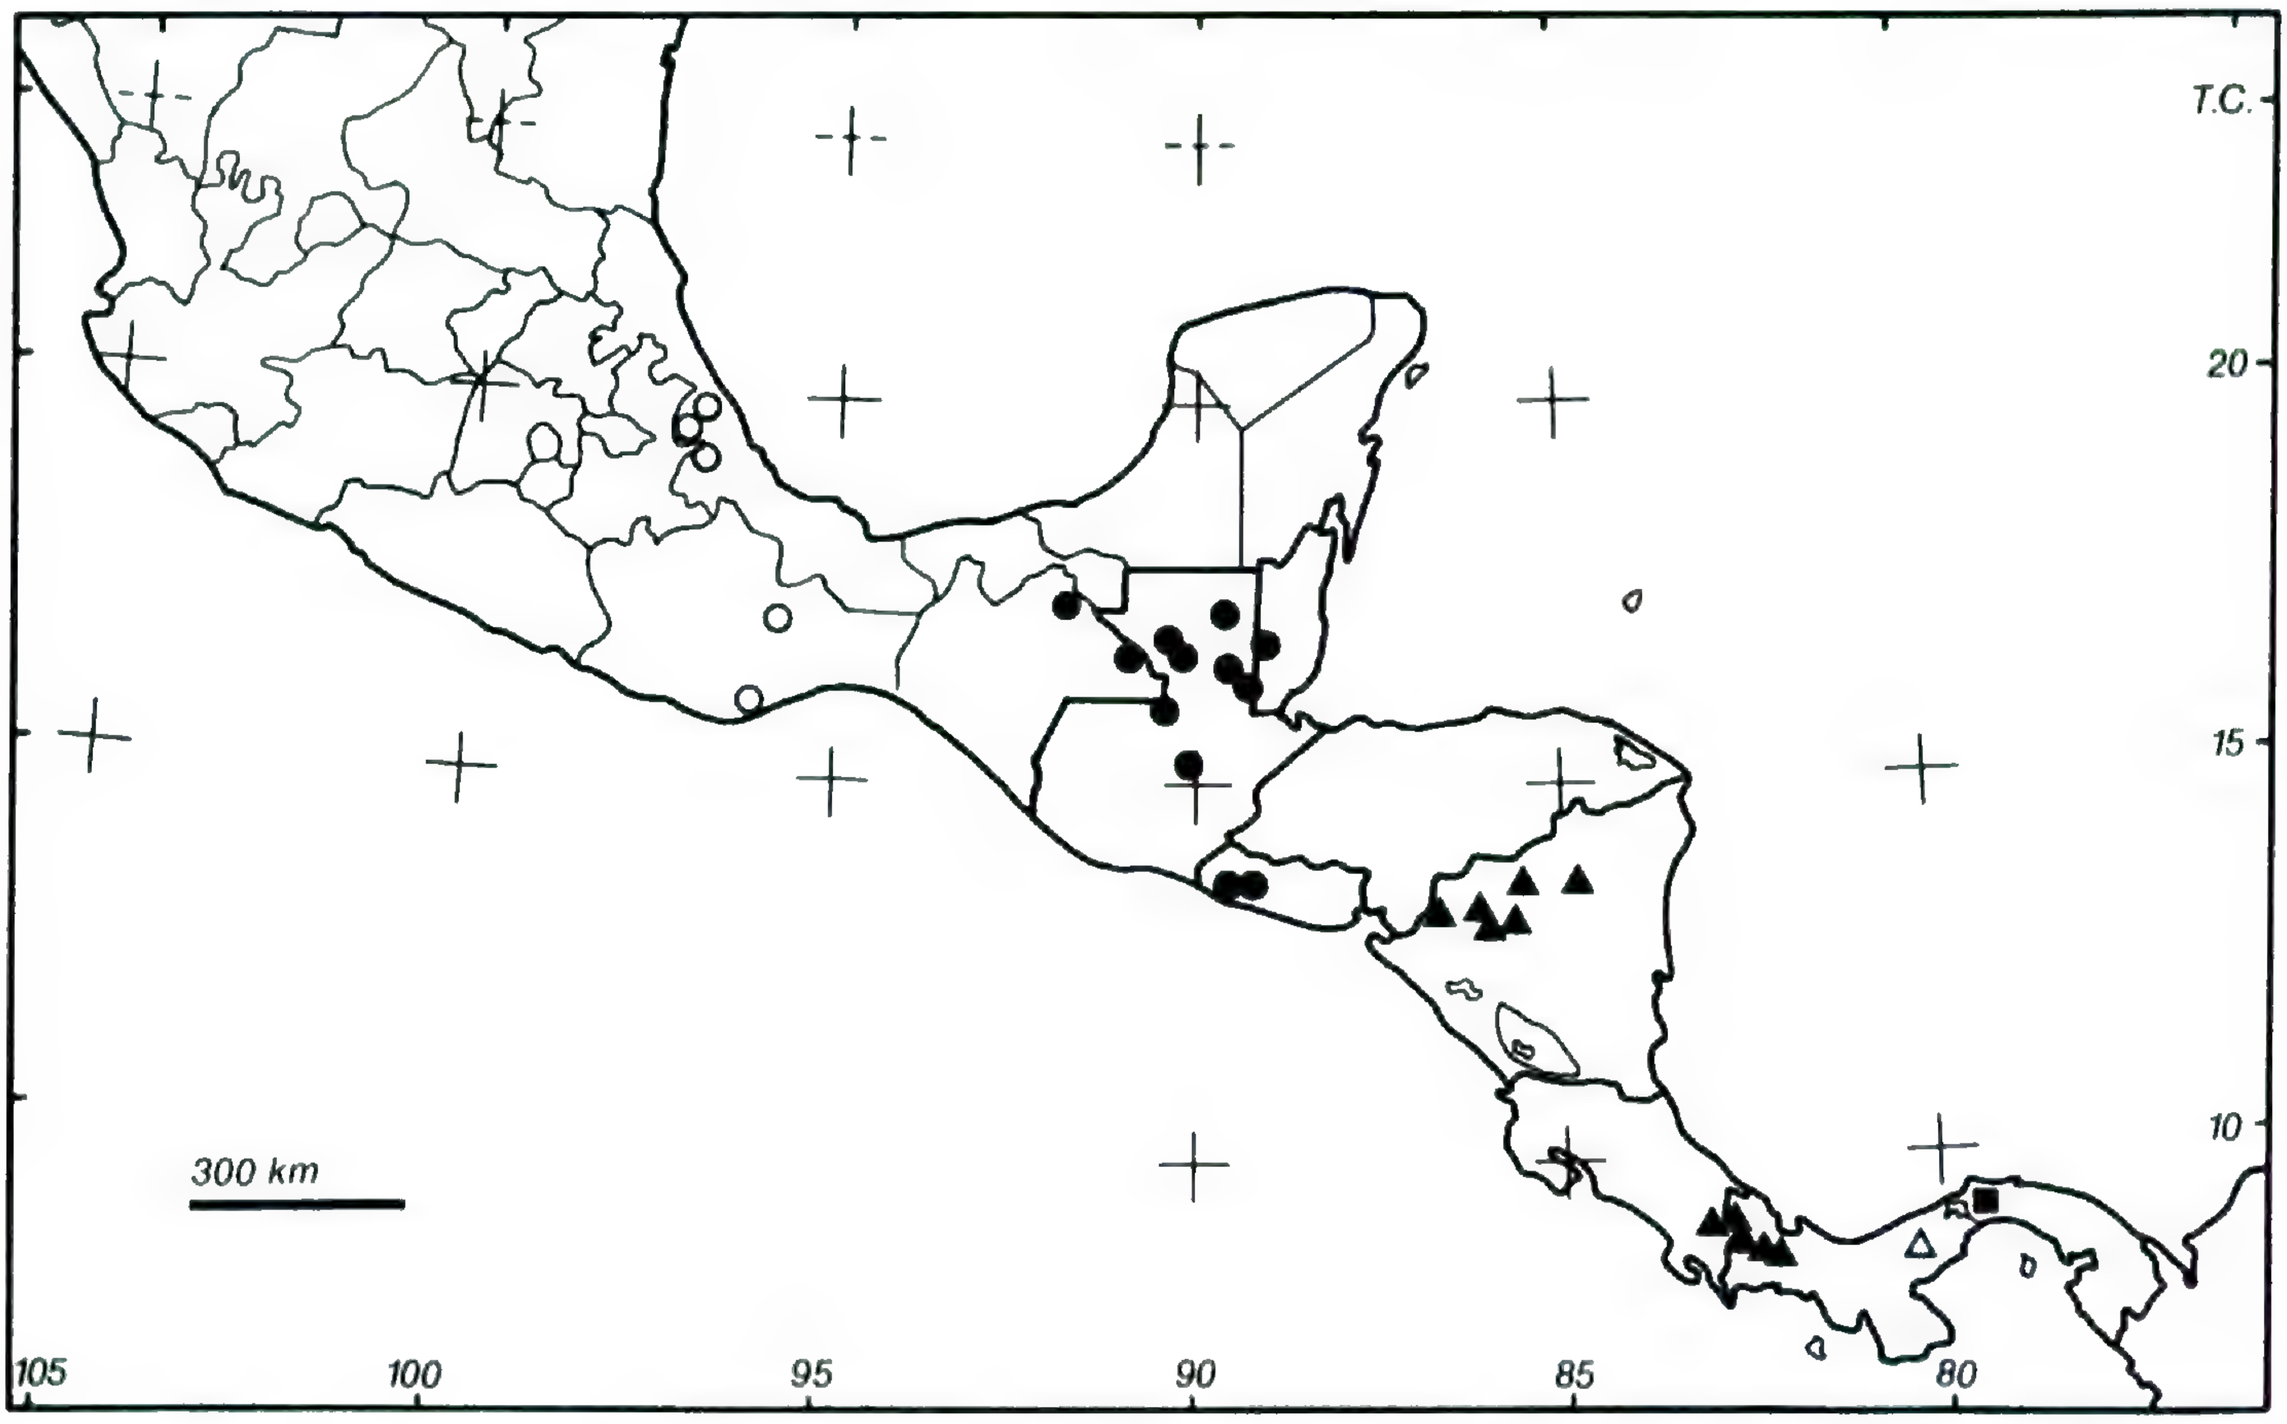

FIGURE 29. Distributions of *Psychotria cascajalensis* (open triangle), *P. chiriquina* (solid triangles), *P. dwyeri* (open circles), *P. lundellii* (solid circles), and *P. olgae* (solid square).

panicle branched to 3 degrees; main axis 6 cm long, the peduncle 2–3.5 cm long; secondary axes in 3 ranks, the first-rank axes 2 or 4, the longer pair 1–2 cm long, the shorter pair 0.4–1.2 cm long when present, the second-rank axes 2, 0.5–0.8 cm long, the third-rank axes 2, 0.1–0.3 cm long; cymes branched to 1–2 degrees; bracts and bracteoles broadly triangular, 1–2 mm long, red-brown pubescent. *Flowers* subsessile, the pedicels 0.5 mm long; calyx cup-shaped, the tube 0.8 mm long, the lobes 5, triangular to barely evident, to 0.3 × 0.8 mm, puberulent, fringed; corolla green-white, the tube cylindrical, 1.5 × 1.5 mm, thickly white pubescent in throat, the lobes 5, triangular, 1.5 × 1 mm; stamens 5, the filaments not seen in pins, 1.5 mm long in thrums, the anthers 1 mm long; style not seen in pins, 1 mm long in thrums, the branches linear. *Fruit* not seen.

Distribution (Fig. 29). Known only from the type collection from the foothills south of the divide in Coclé, Panama, at 480 m in a region of tropical moist to premontane wet forest with equatorial-mountainous climate. It was collected in flower on May 2.

Psychotria cascajalensis may be recognized by its small (usually 3.5–6 × 2–2.7 cm), coriaceous, elliptic leaves and robust pedunculate inflorescences with secondary axes 2(4) per rank in three ranks.

The only flowering collection appears to be a thrum morph.

37. Psychotria chiriquina Standley, Contr. U.S. Natl. Herb. 18: 129. 1916. TYPE: Panama. Chiriquí: Alto de la Cuesta, E slope of Chiriquí Volcano, 2,100–2,200 m, 10–13 Mar. 1911 (fl), *Pittier 3118* (holotype, US). Figure 29.

Shrub or small tree, 1–6 m tall; young stems glabrous, the bark gray, deeply fissured longitudinally; stipules sheathing, ovate, sometimes bilobed, 8–10 × 3–5 mm, glabrous to red-brown puberulent, fringed, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.6–1.5 cm long, glabrous to red-brown puberulent, flat above; blades membranous, elliptic, the apex long-acuminate, the base attenuate, (4–)6.5–9(–12) × (1–)1.5–2.5(–3) cm, glabrous above and below, drying deep red-brown; secondary veins 5–11(–12) pairs, diverging 30°–65°, eucamptodromous, constantly arcuate, prominulous to not elevated below, glabrous, the axils with or without minute tufts of hair; tertiary veins evident to inconspicuous, orthogonal reticulate to percurrent. *Inflorescences* terminal, panicles of cymes; panicle branched to 2–4 degrees; main axis (1–)2–7 cm long, the peduncle lacking or 1–4.5 cm long; secondary axes in 3(4) ranks, the first-rank axes

2, (0.4–)1–3.2 cm long, the second-rank axes 2, (0.3–)0.5–1.4 cm long, the third-rank axes 2, (0.1–)0.3–0.5 cm long, the fourth-rank axes 2, 0.2 cm long; cymes branched to 1–2 degrees; bracts linear, 2–3 mm long, glabrous to ciliate; bracteoles irregular, to 0.8 mm long, sparsely ciliate. *Flowers* sessile to pedicellate, the pedicels to 3 mm long; calyx cup-shaped, the tube 1 mm long, the lobes 5, triangular to barely evident, 0–0.6 × 0.8 mm, glabrous to minute-puberulent; corolla white, the tube cylindrical, 4–6 × 1.5–2 mm, white pubescent in throat, the lobes 5, linear, 1.5–2 × 1 mm; stamens 5, the filaments 4–4.5 mm long in pins, 5.5–6 mm long in thrums, the anthers 1 mm long; style 6 mm long in pins, 4–5 mm long in thrums, the branches minute, clublike. *Fruit* when dry ellipsoid, 5–6 mm long, 4–4.5 mm diam., maturing red, drying deep red-brown; persistent calyx a minute beak to 1 mm long; seed dorsal surface with 4 shallow longitudinal furrows, the ventral surface with 2 shallow longitudinal furrows.

Distribution (Fig. 29). Known from northern Nicaragua and from both sides of the Costa Rica–Panama border at elevations of 900 to 2,500 m in premontane to lower montane moist forest to rainforest with equatorial-mountainous to tropical-mountainous climate. *Psychotria chiriquina* has been collected in flower July–August in Nicaragua and primarily February–May in Costa Rica and Panama, and in fruit November–May in Nicaragua and August–April in Costa Rica and Panama.

Selected specimens examined. NICARAGUA. JINOTEGA: carret. Matagalpa–Jinotega, km 133–134, a 10 km al SE de Jinotega, 13°01′N, 85°55′W, 1,400–1,480 m, 24 Feb. 1979 (fr), *Grijalva & Araquistain 175* (MO); Montaña Cuspire, 13°17′N, 86°09′W, 1,500–1,539 m, 10 Apr. 1981 (fr), *P. NE of Cerro Punta, Cerro Respinga ridge, 13 Jan. 1971 (fl, fr), *Wilbur et al. 13106* (DUKE, MO).

Psychotria chiriquina may be recognized by its small (usually 6.5–9 × 1.5–2.5 cm) narrow-elliptic leaves drying deep red-brown, deeply longitudinally fissured bark, long (4–6 mm) corolla tube, and robust (5–6 × 4–4.5 mm) ellipsoid fruits drying deep red-brown. There are several differences noted in collections from Nicaragua as opposed to those from Panama. Nicaraguan material shows fewer (5–7 vs. usually 8–11[–12]) secondary veins and more acute (30°–50° versus 55°–65°) angles of divergence of secondaries. Panamanian material shows often pedicellate inflorescences and fruits with a more prominent persistent calyx.

38. Psychotria cocosensis C. Hamilton, Phytologia 64: 222. 1988. TYPE: Costa Rica: Cocos Island, 18 June 1898 (fr), *Pittier 12375* (holotype, US). Figures 9c, 28.

Shrub; young stems glabrous, the bark furrowed longitudinally; stipules lanceolate, 12–35 × 2–5 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 7–14 mm long, glabrous, grooved or flat above; blades subcoriaceous to coriaceous, elliptic, the apex acuminate to subcaudate, the base attenuate, (12–)14–17 × 5.5–7 cm, glabrous above and below, drying red-brown to green-brown; secondary veins (9–)10–12 pairs, diverging 45°–50°, eucamptodromous to brochidodromous, straight then arcuate near margin, elevated below in less coriaceous leaves, the axils with small domatia below; tertiary veins inconspicuous to evident, percurrent to reticulate. *Inflorescences* terminal, panicles of cymes; panicle branched to 2–3 degrees; main axis 1 cm long, the peduncle lacking; secondary axes in 2 ranks, the first-rank axes 2, 0.6 cm long, the second-rank axes 2, reduced; cymes branched to

1 degree; bracts triangular, 0.7–1.5 mm long, glabrous. *Flowers* pedicellate, the pedicels 2–3 mm long; calyx cup-shaped, the tube 1 mm long, the lobes 5, broadly triangular to barely evident, glabrous; corolla color unknown, the tube cylindrical, 3 × 3 mm, white pubescent in throat, the lobes 5, linear, 4 × 2 mm; stamens 5, the filaments 7 mm long, the anthers 2 mm long; style 9–10 mm long, the branches minute, linear. *Fruit* when dry spherical to ellipsoid, 6 mm long, 5.5–6 mm diam., drying dark red-brown; persistent calyx cuplike, coriaceous, 1.5 mm long (Fig. 9c); seed dorsal surface with 4 shallow, irregular, longitudinal furrows, the ventral surface with 2 deep, irregular, longitudinal furrows.

Distribution (Fig. 28). Known only from the type locality, Cocos Island, at 50 m elevation in premontane rainforest. *Psychotria cocosensis* has been collected in fruit in January and June.

Additional specimens examined. COSTA RICA. COCOS ISLAND: La vallée de Chatham, 50 m, Jan. 1902 (fl, fr), *Pittier 16279* (GH, US).

Psychotria cocosensis may be recognized by its close resemblance to *P. panamensis* and by its coriaceous leaves and large (6 × 5.5–6 mm) spherical to ellipsoid fruits with calyx persisting as a coriaceous cup ca. 1.5 mm long.

Style and stamens are both exserted in the one flowering collection seen, suggesting strongly that the species is long-homostylous.

39. Psychotria dwyeri C. Hamilton, Phytologia 64: 223. 1988. TYPE: Mexico. Oaxaca: Dto. Choapan (Santiago Choapan), Sta. María, Montaña Sta. María, 1,500 m, 7 Apr. 1938 (fr), *Mexia 9265* (holotype, NY; isotypes, B, F, GH, K, MO, US). Figure 29.

Shrub or small tree, 3–6 m tall; young stems glabrous, the bark smooth; stipules sheathing, triangular, 8–13 × 3–5 mm, glabrous, caducous, leaving a pale ridge often with red-brown fringe. *Leaves* petiolate; petioles (5–)15–40(–45) mm long, glabrous, furrowed above; blades membranous, elliptic, the apex cuspidate, the base cuneate to attenuate, (12 –)15–23 × 5–10 cm, glabrous above, glabrous to minutely white puberulent below, drying green-brown, paler below; secondary veins (12–)15–18 pairs, diverging 55°–70°(–80°), eucamptodromous, straight to slightly arcuate, elevated below, often white puberulent below, the axils lacking domatia or hairs; tertiary veins evident, orthogonal reticulate, the loops near margin evident. *Inflorescences* terminal, panicles of cymes; panicle branched to 4 degrees; main axis 5.5–10.5 cm long, the peduncle lacking or to 2 cm long; secondary axes in 4–5(–6) ranks, the first-rank axes 2, (2.5–)7–9 cm long, the second-rank axes 2(4), (2–)3–5.5 cm long, the third-rank axes 2, (0.5–)1.5–4 cm long, the fourth-rank axes 2(4), (0.5–)1–2 cm long, the fifth-rank axes 2, 0.6–0.8 cm long, the sixth-rank axes 2, 0.3 cm long; cymes branched 1–2 degrees; bracts inconspicuous. *Flowers* pedicellate, the pedicels 0.5–1.5 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, broadly triangular, minute, glabrous to minutely fringed; corolla white, the tube cylindrical, 2–2.5 × 2 mm, white pubescent in throat, the lobes 5, triangular, 1.5–2 × 1 mm; stamens 5, the filaments 2–2.5 mm long in pins, 2.5–3 mm long in thrums, the anthers 1 mm long; style 4–4.5 mm long in pins, 1.5–2 mm long in thrums, the branches linear in pins, clublike in thrums. *Fruit* when dry spherical, 4.5–5 mm long, 4.5–5 mm diam., maturing red, drying deep red-brown; calyx persistent as a beak, to 0.8 mm long; seed dorsal surface with 4 irregular longitudinal furrows, the ventral surface with 2 deep longitudinal furrows.

Distribution (Fig. 29). Known from Veracruz and Oaxaca, Mexico, at elevations of 50–1,500 m in a region of subevergreen forest with tropical to tropical-mountainous climate. This species has been collected in flower in April and May and in fruit April, June, and December.

Specimens examined. MEXICO. OAXACA: Ubero, 30–90 m, June 1937 (fr), *Ll. Williams 9475* (F). VERACRUZ: San Lorenzo Tenochtitlán, 9 Dec. 1967 (st), *Chavelas et al. ES-2832* (MEXU); El Mirador, 1853 (fl), *F. Muller 424* (NY); Apr. 1932 (fl), *Purpus 14124* (A, F); Zacuapan, 1915 (fl), *Purpus 7525* (MO, US); May 1926 (fl), *Purpus 10705* (US); Jalapa, 1,200–1,350 m, 1894 (fl), *C. Smith 1844* (F, US).

Psychotria dwyeri resembles *P. panamensis* in inflorescence and vegetative characters and is distinguished most easily in fruit. *Psychotria dwyeri* has spherical (vs. ellipsoid to obovoid) fruit 4.5–5 mm (vs. 4.5–8 mm) long.

Reproductive organs at both levels appear to be longer in the pin morph than in the thrum.

40. Psychotria hornitensis Dwyer & C. Hamilton in C. Hamilton, Phytologia 64: 225. 1988. TYPE: Panama. Chiriquí: ridge and summit of Cerro Hornito, above Los Planes de Hornito, 8°42′N, 82°06′W, 2,100 m, 14 Mar. 1982 (fl, early fr), *Knapp et al. 4198* (holotype, MO). Figure 30.

Shrub 2 m tall; young stems glabrous, the bark deeply furrowed longitudinally; stipules sheathing,

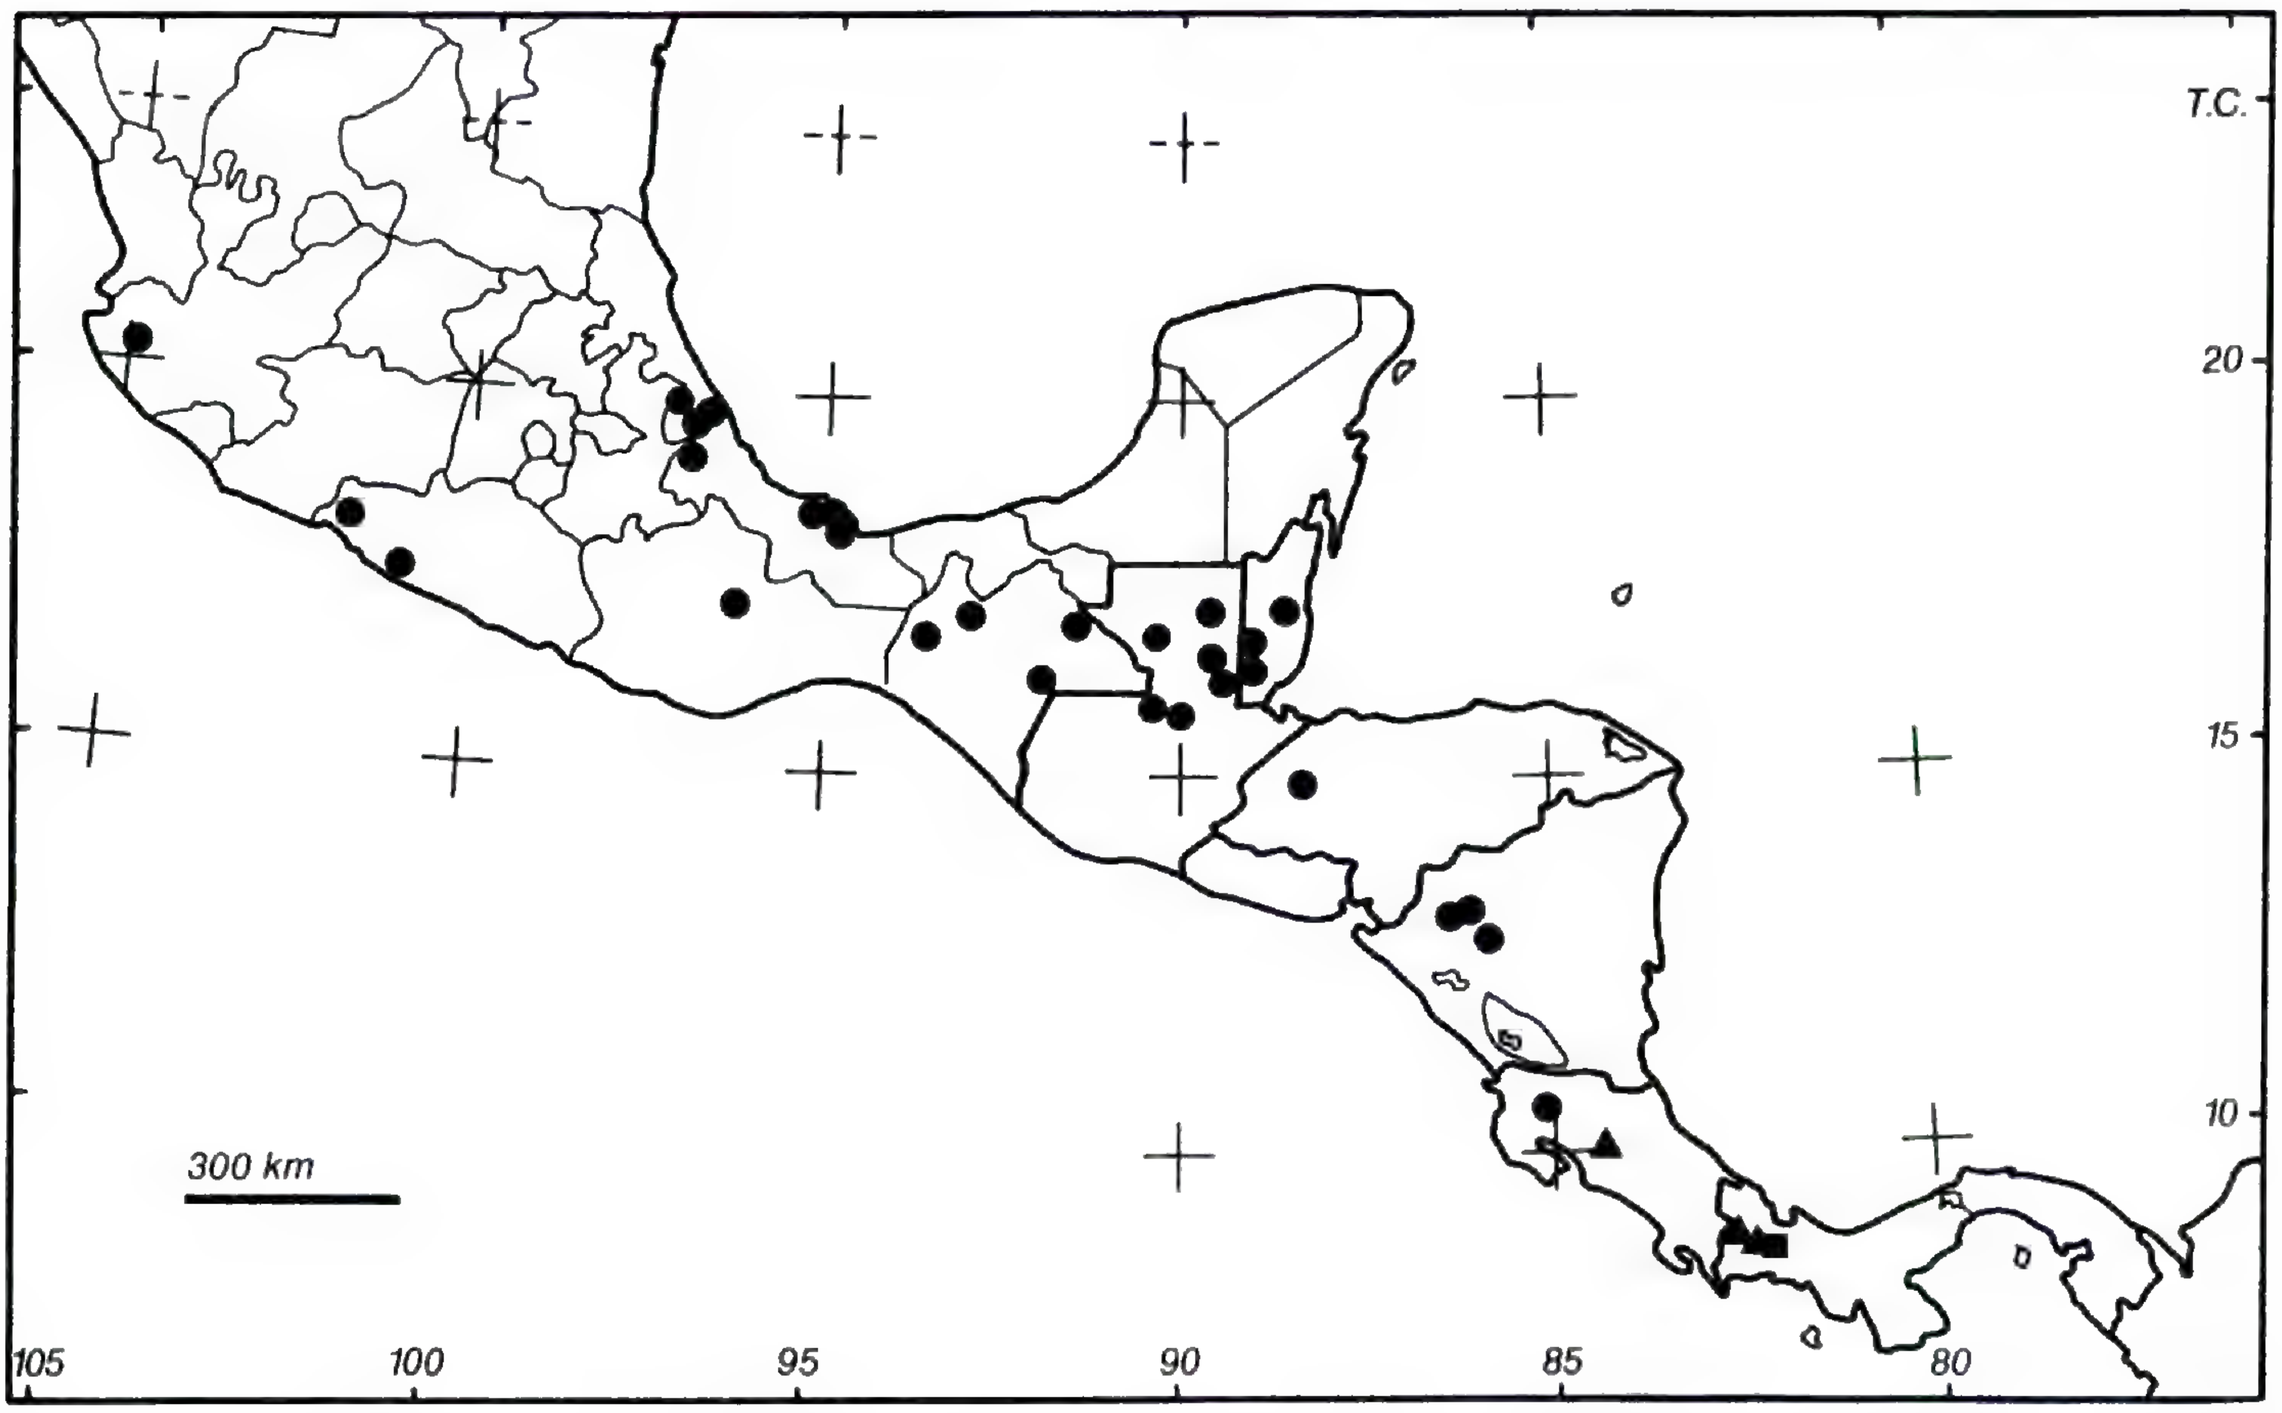

FIGURE 30. Distributions of *Psychotria hornitensis* (square), *P. mexiae* (circles), and *P. stockwellii* (triangles) in Mesoamerica.

ovate to lanceolate, 3–4 × 1–1.5 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* subsessile; petioles to 2 mm long, glabrous, flat above; blades membranous, narrowly elliptic, the apex long acuminate, the base attenuate, 2.5–3.5 × 0.5–0.7 cm, glabrous above and below, drying dull green-brown above, dull green below; secondary veins 5–6 pairs, diverging ca. 50°, eucamptodromous, constantly arcuate, not evident above, barely evident below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous. *Inflorescences* terminal, panicles of 3–5 individual flowers or cymes; panicle branched to 2 degrees; main axis 2.5–3 cm long, the peduncle 1.5–2 cm long; secondary axes in 1–2 ranks, the first-rank axes 1–2, 0.3–0.4 cm long, the second-rank axes 1–2, 0.1 cm long; cymes branched to 1 degree; bracts and bracteoles linear, 1.5–2 × 0.7 mm, glabrous to puberulent within near base. *Flowers* sessile to pedicellate, the pedicels to 1 mm long; calyx cup-shaped, the tube ca. 1 mm long; the lobes 5, triangular, 0.8–1 × 0.8 mm, glabrous; corolla white, the tube cylindrical, 3.5–4 × 1.5 mm, white pubescent in throat, the lobes 5, ovate, 1–1.5 × 0.8 mm; stamens 5, 3–4 mm long, the anthers 1 mm long; style 4–6 mm long, the branches short, linear. Mature *fruit* not seen.

Distribution (Fig. 30). Known only from the type locality, Cerro Hornito, Chiriquí, Panama, at ca. 2,000 m elevation in low montane rainforest with equatorial-mountainous climate. *Psychotria hornitensis* has been collected in flower in February and March and with immature fruit in March.

Additional specimen examined. PANAMA. CHIRIQUÍ: ridge nr. top of Cerro Hornito, 1,950 m, 15 Feb. 1979 (fl), *Hammel 6189* (MO).

Psychotria hornitensis may be recognized readily by its small, narrow (2.5–3.5 × 0.5–0.7 cm) leaves and small (2.5–3 cm long) few-flowered inflorescences.

The one flower morph found does not show significant differentiation in length between the exserted style and stamens, so the species is presumed to be long-homostylous.

41. Psychotria lundellii Standley in Lundell, Contr. Univ. Michigan Herb. 4: 29. TYPE: Belize. Cayo: Valentin, 26 June 1936 (fl), *Lundell 6260* (holotype, F; isotypes, GH, MICH, n.v., NY, US). Figure 29.

Tree or shrub, (1–)2–15 m tall; young stems glabrous or red-brown puberulent, the bark pale, cracked and furrowed longitudinally; stipules ovate, rounded, 5–6 × 2–4 mm, glabrous, often ciliate, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.8–2 cm long, glabrous, grooved above; blades subcoriaceous, elliptic, the

apex acuminate, the base attenuate, (5–)7.5–15 × (1.8–)2.5–5 cm, glabrous above and below, drying pale to glossy red-brown; secondary veins (5–)6–8(–12) pairs, diverging (30°–)60°–65°, brochidodromous, constantly arcuate, prominulous below, glabrous, the axils usually with minute tufts of red-brown hair and/or domatia below; tertiary veins not evident. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to (3)4 degrees; main axis 4–7.5 cm long, the peduncle (0–)1–3 cm long; secondary axes in 4(5) ranks, the first-rank axes 2(4), the longer pair 1.5–3.5 cm long, the shorter pair when present 1.6 cm long, the second-rank axes 2, 0.8–1.7 cm long, the third-rank axes 2, 0.5–0.7 cm long, the fourth-rank axes 2, 0.2–0.3 cm long, the fifth-rank axes 2, 0.2 cm long; cymes branched to 1–2 degrees; bracts sheathing, irregular, to 1.5 mm long, ciliate; bracteoles triangular, 0.3–0.5 mm long, ciliate. *Flowers* pedicellate, the pedicels 0.7–1 mm long; calyx cup-shaped, the tube 0.5 mm long, the lobes 5, triangular, 0.3 × 0.6 mm, minutely ciliate; corolla green-white, the tube campanulate, 2–2.5 × 1.5 mm, white pubescent in throat, the lobes 5, ovate-acuminate, 1.5–2 × 1 mm; stamens 5, the filaments 1.5–2 mm long in pins, 4 mm long in thrums, the anthers 0.7 mm long; style 3–4 mm long in pins, 2 mm long in thrums, the branches linear. *Fruit* spherical when dry, (4–)4.5–5(–5.5) mm long, (4–)4.5–5(–5.5) mm diam., maturing red, drying red-brown; persistent calyx not conspicuous or rarely to 0.3 mm long; seed dorsal surface with 3–6 shallow irregular longitudinal furrows, the ventral surface with 2 deep and often 2–4 additional irregular longitudinal furrows.

Distribution (Fig. 29). Eastern Chiapas, Guatemala, western Belize, and El Salvador, at elevations below 500 m except in El Salvador, where this species occurs at 1,800–2,000 m. It is found in evergreen forest with equatorial-tropical or sometimes tropical to tropical-mountainous climate. *Psychotria lundellii* has been collected in flower April–July and in fruit July–April, primarily January–March.

Selected specimens examined. MEXICO. CHIAPAS: 23 mi. SE of Palenque, rd. to Chancala, 160 m, 6 July 1977 (fl), *Croat 40294* (MO); Mpio. EL SALVADOR. SAN SALVADOR: Volcán San Salvador, forest El Picacho NE of El Boquerón, 1,950 m, 1 Mar. 1968 (fr), *A. Molina R. & Montalva 21831* (F, NY). SONSONATE: Sierra Apaneca, cut-over forest, Cerro El Pilón, 1,800 m, 23 Feb. 1968 (fr), *A. Molina R. & Montalvo 21607* (F, NY).

Psychotria lundellii may be recognized by its narrow (length/width = 3) leaves drying glossy red-brown with few (usually 6–8) secondary veins and tertiary veins not evident, and its spherical fruit drying often glossy red-brown and appearing smooth outside due to the seed dorsal surface having 3–6 shallow irregular longitudinal furrows. *Psychotria lundellii* differs from the similar *P. chiriquina* in having smaller (5–6 vs. 8–10 mm long) stipules, brochidodromous (vs. eucamptodromous) secondary venation, shorter (2–2.5 vs. 4–6 mm) corolla tubes, and spherical (vs. ellipsoid) fruits. Material from El Salvador shows generally more secondary veins in the leaves than material gathered elsewhere.

Eight flowering specimens from Belize have been examined, and only the long-style morph has been found, suggesting that the short-style morph has been lost in populations in that country. One thrum has been found in Baja Verapaz, Guatemala (*Lundell & Contreras 21037*).

42. Psychotria mexiae Standley, Publ. Field Columbian Mus., Bot. Ser. 4: 296. 1929. TYPE: Mexico. Jalisco: Santa Cruz de Vallarta, wooded ravine on mountain side, 300 m, 9 Dec. 1926 (fr), *Mexia 1262* (holotype, F; isotypes, A, GH, MO, US–2 sheets). Figures 10h, 30.

Palicourea nigrescens M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 11(50): 136. 1844. TYPE: Mexico. Veracruz: Cordillera, June–Oct. 1840 (fl), *Galeotti 2653* (holotype, C). Not *Psychotria nigrescens* De Wild., Pl. Bequaert. 2: 393. 1924.

Psychotria schippii Standley & Steyermark, Publ. Field Mus. Nat. Hist., Bot. Ser. 23: 24. 1943. TYPE: Belize. Cayo: Valentin, limestone valley, June–July 1936 (fr), *Lundell 6193* (holotype, F; isotypes, GH, NY, US).

Tree or shrub, 2–5(–10) m tall; young stems sparsely puberulent, the bark pale, mottled, with

irregular ridges and raised lenticels; stipules sheathing, linear, 12–20(–40) × 1.5–3(–5) mm, glabrous, caducous, leaving a pale ridge with or without red-brown fringe. *Leaves* petiolate; petioles 3–20 mm long, glabrous or sometimes sparsely tomentose below, flat above; blades membranous to subcoriaceous, elliptic, the apex long-acuminate, the base cuneate, (8–)10–20 × (2.5–)3–8.5 cm, glabrous above and below, sometimes sparsely tomentose along midvein below, drying green-brown to sometimes red-brown, the veins often reddish below; secondary veins 12–16(–18) pairs, diverging (55°–)60°–70°(–75°), brochidodromous to eucamptodromous, constantly arcuate, prominent below, glabrous, the axils sometimes with minute tufts of hairs below; tertiary veins inconspicuous to evident, orthogonal reticulate to rarely random reticulate. *Inflorescences* terminal or pseudoaxillary, globose panicles of cymes; panicle branched to 4 degrees; main axis (1–)2–4.5 cm long, the peduncle lacking; secondary axes in (3)4(5) ranks, the first-rank axes 2 or 4, equal, 1–3 cm long, the second-rank axes 2 or 4, equal, 0.5–1.5 cm long, the third-rank axes 2, 0.2–1 cm long, the fourth-rank axes 2, 0.2–0.7 cm long, the fifth-rank axes 2, 0.1 cm long; cymes branched to (1)2 degrees; bracts and bracteoles not evident. *Flowers* on pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.3 mm long, sometimes minutely puberulent; corolla white, often drying pink, the tube cylindrical, 2.5–4.5 × 1.5 mm, white pubescent in throat, the lobes 5, lanceolate, 1.5–2 × 1 mm; stamens 5, the filaments 2–3.5 mm long in pins, 3–5 mm long in thrums, the anthers 0.8–1 mm long; style 4–7 mm long in pins, 2–3 mm long in thrums, the branches spathulate. *Fruit* when dry ellipsoid to spherical, 4.5–5(–6) mm long, 3.5–4.5(–5) mm diam., maturing red, drying often shiny red-brown; persistent calyx a tubular beak to 0.5 mm long; seed dorsal surface with 5–8 deep irregular longitudinal furrows, the ventral surface with 2 deep regular plus usually 2–4 additional irregular longitudinal furrows (Fig. 10h).

Distribution (Fig. 30). Scattered from Mexico through northern Costa Rica, most common in a band from Veracruz and Chiapas, Mexico, through Petén, Guatemala, into Belize, at elevations of 400–1,800 m in regions of premontane moist forest with equatorial to tropical climate. *Psychotria mexiae* has been collected in flower February–July and in fruit September–April.

Palicourea nigrescens and *Psychotria schippii* are morphologically identical to *P. mexiae* and are therefore included. The existing name *Psychotria nigrescens* De Wild. (dating to 1924) leaves "*mexiae*" as the oldest available epithet.

Psychotria mexiae may be recognized by its elliptic long-acuminate leaves drying green-brown to red-brown with veins drying reddish below; globose panicles without peduncle and with 4 equal secondary axes in each of the first 2 ranks; long (2.5–4.5 mm) corolla tube often drying pink; and ellipsoid to spherical fruit drying often shiny red-brown and appearing smooth outside due to the irregularity of the furrows on the dorsal surface of the seed. Corolla tubes are shorter in specimens from Belize (2.5 mm) than in those from Mexico (4–4.5 mm), and the stamens and styles are scaled down accordingly. Fruits are larger (5–6 mm long) in specimens from Veracruz and Guatemala than from elsewhere (4.5–5 mm long).

The exserted pistil of the pin morph is usually longer than the exserted stamens of the thrum (4–7 vs. 3.5–5.5 mm).

43. Psychotria olgae Dwyer & Hayden, Ann. Missouri Bot. Gard. 55: 42, fig. 3. 1968. TYPE: Panama. Panamá: between Cerro Jefe and Eneida, 630–870 m, 17 Jan. 1968 (fr), *Dwyer et al. 8193* (holotype, MO; isotypes, DUKE, F, NY). Figures 10g, 29.

Tree 2–8(–10) m tall; young stems puberulent, the bark pale, slightly ridged longitudinally; stipules lanceolate, sometimes biacuminate, 3–5 × 1.5 mm, ciliate at apex, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 2–3 mm long, glabrous, flat above, robust; blades coriaceous, elliptic to obovate, the apex obtuse to rounded, the base subcordate, the margins inrolled, (5–)6–10 × (1.5–)2.5–4.5 cm, glabrous above and below, drying green-brown to red-brown; secondary veins 5–7 pairs, diverging 60°–65°, eucamptodromous to brochidodromous, constantly arcuate, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins not evident. *Inflorescences* terminal or pseudoaxillary, panicles of glomerules; panicle branched to 3 degrees; main axis 2.5–9 cm long, the peduncle 1.5–5.5 cm long; secondary axes in 2 ranks, the first-rank axes 2, 1–3 cm long, the second-rank axes 2, 0.4–1 cm long; bracts and bracteoles irregular, 1 mm long, ciliate. *Flowers* pedicellate, the pedicels 2–3 mm long; calyx cup-shaped, the tube 1 mm long, the lobes 5, broad triangular to not evident, to 0.5 mm long, minutely ciliate; corolla green, leathery, the tube cylindrical, 2.5–3.5 × 2 mm, white pubescent in throat, the lobes 5, ovate, 2.5–3 × 1.5 mm; stamens 5, the filaments 3–3.5 mm long in pins, 4 mm long in thrums, the anthers 1–1.5 mm long; style 6 mm long in pins, 2.5–3 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid to slightly obovoid, 9–10 mm long, 5.5–7 mm diam., maturing red, drying red-brown; persistent calyx a tubular beak to 1 mm long; seed dorsal surface with 4 deep regular and numerous irregular longitudinal furrows, the ventral surface with 2 deep regular and several irregular longitudinal furrows (Fig. 10g).

Distribution (Fig. 29). Known only from the region of Cerro Jefe, eastern Panamá Province, Panama, at 800–1,200 m elevation in premontane wet forest with equatorial-mountainous climate. This species has been collected in flower in March, June, and July and in fruit in October and January.

Additional specimens examined. PANAMA. PANAMÁ: Cerro Jefe, to 930 m, 12 Mar. 1968 (fl), *Dwyer et al. 7288* (F, MO); rd. from Pan-American Hwy. to Cerro Jefe, 21.7 km from Pan-Am. Hwy., 22 June 1977 (fl), *Folsom 3817* (CR, MO); Cerro Jefe, on top nr. antenna, ca. 1,200 m, 19 Jan. 1977 (fr), *Folsom & Harp 1368* (CR, MO); Cerro Jefe region, 1,000 m, 8 Jan. 1975 (fr), *Luteyn & Wilbur 4655* (DUKE); Cerro Jefe, ca. 1,000 m, 14 July 1975 (fl), *Mori 7122* (MO, US); 14 July 1975 (fl), *Mori 7133* (MO); 5 June 1975 (fl), *Mori & Kallunki 6507* (MO—2 sheets, US); Cerro Jefe, 1.5 km before weather station, 850–900 m, 8 Oct. 1980 (fr), *Sytsma 1504* (MO); Cerro Jefe, 850–900 m, 29 Oct. 1980 (fr), *Sytsma 1990* (MO).

Psychotria olgae may be recognized by its coriaceous leaves with subcordate base and inrolled margins and by its large (9–10 × 5.5–7 mm) ellipsoid to slightly obovoid fruit.

The reproductive organs are longer at both levels in the pin morph that in the thrum.

44. Psychotria panamensis Standley, Contr. U.S. Natl. Herb. 18: 132. 1916. TYPE: Panama. Chiriquí: S slope of Cerro Horqueta, Los Siguas Camp, ca. 1,700 m, 17–19 Mar. 1911 (fl, fr), *Pittier 3194* (holotype, US). Figures 2d, 7e, 28.

Shrub or tree, (1–)2–13 m tall; young stems minutely puberulent to short-ferrugineous pubescent, the bark usually furrowed longitudinally; stipules usually sheathing, lanceolate, (10–)20–80 × (2.5–)3.5–7 mm, glabrous, minutely puberulent or red-brown ciliate, caducous, leaving a pale ridge with red-brown fringe (Fig. 2d). *Leaves* petiolate; petioles (0.5–)2–4.5(–5) cm long, glabrous or puberulent, flat or grooved above; blades membranous

to subcoriaceous, elliptic to obovate, the apex acuminate, the base subcordate to cuneate, (7–)9–28 × (2.5–)4–11(–13) cm, glabrous above and below, the midvein sometimes puberulent below, drying red-brown to green-brown; secondary veins (6–)8–19(–22) pairs, diverging 45°–70°, eucamptodromous to sometimes brochidodromous, constantly arcuate or straight then arcuate near margin, elevated below, glabrous or minute-puberulent, the axils lacking domatia or hairs, or having segments of red-brown hairs along midvein and secondary vein; tertiary veins inconspicuous, orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, panicles of cymes or glomerules (Fig. 7e); panicle branched to 3–5 degrees; main axis 1.5–12 cm long, the peduncle usually lacking or 1.5–3 cm long; secondary axes in 3–7(–8) ranks, the first-rank axes 2 or 4, equal or subequal, 0.8–7 cm long, the second-rank axes 2, 0.4–4 cm long, the third-rank axes 2, 0.2–3 cm long, the fourth-rank axes 2, 0.2–2 cm long, the fifth-rank axes 2, 0.1–1 cm long, the sixth-rank axes 2, 0.2–0.6 cm long, the seventh-rank axes 2, 0.1–0.2 cm long, the eighth-rank axes 2, 0.1 cm long; cymes branched to 1–3 degrees; bracts and bracteoles irregular or not evident, to 1 mm long, ciliate. *Flowers* pedicellate, the pedicels 0.5–1 mm long, sometimes (var. *ixtlanensis*) with minute spheroidal glands; calyx cup-shaped, the tube 0.3–0.5 mm long, the lobes 0 or 5, triangular to not evident, to 0.3 mm long, minutely ciliate; corolla white or cream, the tube cylindrical, 2–3 × 1.5–2 mm, white pubescent in throat, the lobes 5, lanceolate or triangular, 1.5–2.5 × 0.8–1 mm; stamens 5, the filaments 2–3 mm long in pins, 3.5–5 mm long in thrums, the anthers 0.7–1 mm long; style 4–6 mm long in pins, 2.5–3 mm long in thrums, the branches clublike, spathulate, or linear. *Fruit* when dry ellipsoid to obovoid, 4.5–8 mm long, 3.5–6.5(–7) mm diam., maturing red, drying red-brown to sometimes (var. *ixtlanensis*) red-black; persistent calyx inconspicuous or a beak to 1 mm long; seed dorsal surface with 4 deep irregular or 7–10 irregular longitudinal furrows, the ventral surface with 2 central furrows often plus 2 deep or several irregular lateral longitudinal furrows.

Distribution (Fig. 28). Southern Mexico through Panama, at elevations of 0–2,100 m. Varieties *compressicaulis* and *magna* occur at lower elevations, while varieties *ixtlanensis* and *panamensis* occur mostly above 1,000 m.

Psychotria panamensis may be recognized by its large (usually 20–80 mm long) lanceolate sheathing stipules, leaves drying usually dark red-brown, inflorescences with robust secondary axes usually 2 per rank in 3–7(–8) ranks and usually with no peduncle, and large (usually 4.5–8 × 3.5–6.5 mm) ellipsoid fruit drying almost always red-brown and without a conspicuous persistent calyx.

KEY TO VARIETIES OF *PSYCHOTRIA PANAMENSIS*

1a. Inflorescence main axis 1.5–3 cm long, the secondary axes in 3(4) ranks; fruit obovoid; endemic to Oaxaca ..... 44b. var. *ixtlanensis*
1b. Inflorescence main axis 5–12 cm long, the secondary axes in 5–7 ranks; fruit usually ellipsoid.
  2a. Fruit 4.5–5 × 3.5–4 mm; Caribbean eastern Panama ..... 44c. var. *magna*
  2b. Fruit 5.5 × 4.5 mm and larger.
    3a. Leaf blades 15–28 × 5.5–13 cm, the secondary veins 16–19; fruit 5.5–7 × 4.5–6 mm; lowland Caribbean Nicaragua and Costa Rica ..... 44a. var. *compressicaulis*
    3b. Leaf blades generally 9–15 × 4–6 cm, the secondary veins 8–16; fruit generally 7–8 × 5.5–6.5 mm; Mexico through Panama, mostly above 500 m ..... 44d. var. *panamensis*

44a. Psychotria panamensis Standley var. **compressicaulis** (K. Krause) C. Hamilton, Phytologia 64: 233. 1988. *Psychotria compressicaulis* K. Krause, Bot. Jahrb. Syst. 54: Beibl. 119: 44. 1916. TYPE: Costa Rica. Cartago: Tuis, 600 m, July 1898 (fl), *Pittier 12412* (holotype, B, destroyed, photo, GH; isotype, US). Figure 28.

Shrub or *tree* (1–)2–10 m tall; stipules sheathing, lanceolate, (10–)20–35 × (3–)3.5–5 mm, glabrous. *Leaves:* blades membranous, the base cuneate to rarely subcordate, (8–)15–28 × (3–)5.5–13 cm, drying dark red-brown; secondary veins (13–)16–19(–20) pairs, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate to percurrent. *Inflorescences:* panicle branched to 4–5 degrees; main axis 7–9 cm long, the peduncle usually lacking or ca. 1.5 cm long; secondary axes in 6–7 ranks, the first-rank axes 2, 4.5–7 cm long, the second-rank axes 2, 2.2–4 cm long, the third-rank axes 2, 1–2 cm long, the fourth-rank axes 2, 0.8–1.5 cm long, the fifth-rank axes 2, 0.4–0.9 cm long, the sixth-rank axes 2, 0.2–0.6 cm long, the seventh-rank axes 2, 0.1–0.2 cm long; cymes branched to 2 degrees. *Flowers:* corolla white, the tube 2–2.5 × 1.5–2 mm, the lobes lanceolate, 1.5–2 × 1 mm; stamens 5, the filaments not seen in pins, 3.5–4 mm long in thrums; style not seen in pins, 2.5–3 mm long in thrums, the branches linear. *Fruit* when dry ellipsoid, 5.5–7 mm long, 4.5–6 mm diam., drying

red-brown; persistent calyx not evident; seed dorsal surface with 4 deep irregular longitudinal furrows, the ventral surface with 2 deep incompletely divided plus several irregular longitudinal furrows.

Distribution (Fig. 28). Caribbean lowlands of Nicaragua and Costa Rica, at 0–200 m elevation in tropical moist to wet (to premontane wet) forest with equatorial climate. This variety has been collected in flower July–August and in fruit November–July.

Selected specimens examined. NICARAGUA. RÍO SAN JUAN: nr. Caño Chontaleño, 20 km NE of El Castillo, Río Indio watershed, 200 m, 7–9 Mar. 1978 (fr), *Neill 3402* (MO). ZELAYA: Mpio. de Nueva Guinea, Bocas de Piedra, 2 Nov. 1982 (st), *Laguna 131* (MO); logging camp nr. Qda. La Talolinga, 11°51′N, 84°26′W, 170 m, 19 Aug. 1983 (fl), *J. Miller & Sandino 1165* (MO); Monkey Point, 3 km al S, 11°37′N, 83°40′W, 10 m, 24 Oct. 1981 (early fr), *P. P. Moreno & Sandino 12259* (MO); Río Punta Gorda, Atlanta, "La Richard," 200 m al SE, 11°32′N, 84°05′W, 20 m, 13 Nov. 1981 (fr), *P. P. Moreno & Sandino 13027a* (MO); new rd. to Mina Nueva America, leading more or less W from 14.3 km N of El Empalme on main rd. to Rosita, 7.7 km from main rd., 23 Feb. 1979 (fr), *W. D. Stevens 12708* (MO); vic. junction of rd. to Alamikamba with rd. between El Empalme and Limbaika, 13°32′N, 84°30′W, 25 m, 24 Feb. 1979 (fr), *W. D. Stevens 12740* (MO). COSTA RICA. ALAJUELA: 2–3 km NW of Bajo, Rodríguez, ca. 30 km N of La Balsa de San Ramón, 300 m, 8 June 1976 (fr), *J. Utley & K. Utley 5137* (DUKE). HEREDIA: Finca La Selva, the OTS field station on the Río Puerto Viejo, 100 m, 5 Apr. 1979 (fr), *Beach 1418* (CR, DUKE, MO); 4 Aug. 1980 (fl), *MacDougal 1092* (DUKE); Sarapiquí, Tirimbina, Istarú Farm, 220 m, 26 Nov. 1971 (fr), *Lent 2246* (CR, DUKE, MO, NY, US). PUNTARENAS: Corcovado National Park, slopes above Llorona, 8°36′N, 83°42′W, 13 July 1977 (fl), *Liesner 3263* (CR, MO).

All eleven flowering collections are thrum morphs, suggesting that the variety is thrum-monomorphic.

44b. Psychotria panamensis Standley var. **ixtlanensis** C. Hamilton, Phytologia 64: 233. 1988. TYPE: Mexico. Oaxaca: Dto. de Ixtlán, 21.4 km al S de Valle Nacional, 17°41′N, 96°18′W, 1,140 m, 28 Nov. 1979 (fr), *Wendt et al. 2258* (holotype, MEXU—317322; isotype, ENCB). Figure 28.

Shrub 2–4 m tall; stipules lanceolate-acuminate, (10–)30–60 × (2.5–)5–7 mm, minutely puberulent. *Leaves:* blades membranous, the base cuneate to attenuate, (9–)16–21 × (3–)5–7.5 cm, drying green-brown; secondary veins 12–17 pairs, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences:* panicle branched to 3–4 degrees; main axis 1.5–3 cm long, the peduncle lacking; secondary axes in 3(4) ranks, the first-rank axes (2)4, subequal, 0.8–2.2 cm long, the second-rank axes 2, 0.4–1.0 cm long, the third-rank axes 2, 0.2–0.6 cm long, the fourth-rank axes 2, 0.2 cm long; cymes branched to 1–2 degrees. *Flowers:* corolla cream, the tube 3 × 1.5 mm, the lobes triangular, 1.5 × 1 mm; stamens 5, the filaments 2–2.5 mm long in pins, not seen in thrums; style 4 mm long in pins, not seen in thrums, the branches short, club-like. *Fruit* when dry obovoid, 5–6 mm long, 4–4.5 mm diam., drying dark red-brown to red-black; persistent calyx inconspicuous or a minute beak to 0.5 mm long; seed dorsal surface with 4 deep irregular longitudinal furrows, the ventral surface with 2 incompletely divided central plus 2 deep lateral longitudinal furrows.

Distribution (Fig. 28). Known only from type region of Ixtlán, Oaxaca, Mexico, at ca. 900–1,140 m elevation in a region of evergreen to subevergreen forest with tropical-mountainous climate. This variety has been collected in flower April–June and in fruit September, November, and April.

Selected specimens examined. MEXICO. OAXACA: Dto. de Ixtlán, Sierra de Juárez, a 2.5 km al NE de Puerto Eligio, 900 m, 2 June 1983 (fl), *Cedillo & Lorence 2397* (MEXU); entre Vista Hermosa y Comaltepec, a 1.5 km al S de Vista Hermosa, Sierra Juárez, 16 Sep. 1965 (fr), *G. Martínez C. 296* (ENCB, MO); Dto. de Ixtlán, 5.3 km al N de Vista Hermosa, carr. a Oaxaca–Tuxtepec, 27 Sep. 1982 (fr), *Torres & Cedillo 1461* (ENCB, MEXU).

This variety, with its leaves drying greenish and fruit obovoid, may be the result of local introgression involving *Psychotria trichotoma* in the Ixtlán region of Oaxaca.

Four flowering collections are all of the pin morph, suggesting (albeit weakly; $p = 0.125$) that the variety may be pin-monomorphic.

44c. Psychotria panamensis Standley var. **magna** (Standley) C. Hamilton, Phytologia 64: 234. 1988. *Psychotria magna* Standl., Contr. U.S. Natl. Herb. 18: 131. 1916. TYPE: Panama. Colón: Loma de la Gloria, nr. Fató (Nombre de Dios), 10–104 m, Aug. 1911 (fl), *Pittier 4092* (holotype, US-679188; isotype, US-693188). Figure 28.

Shrub; stipules not seen. *Leaves:* blades membranous, the base cuneate, 17–24 × 7–11 cm, drying red-brown; secondary veins 14–22 pairs, the axils lacking domatia or hairs; tertiary veins inconspicuous, percurrent. *Inflorescences:* panicle branched to 5 degrees; main axis 10–12 cm long, the peduncle lacking; secondary axes in 6 ranks,

the first-rank axes 2, 6 cm long, the second-rank axes 2, 4 cm long, the third-rank axes 2, 3 cm long, the fourth-rank axes 2, 2 cm long, the fifth-rank axes 2, 1 cm long, the sixth-rank axes 2, 0.6 cm long; cymes branched to 1–3 degrees. *Flowers:* corolla color unknown, the tube 2–2.5 × 1.5 mm, the lobes lanceolate, 1.5–2 × 0.8 mm; stamens 5, the filaments not seen in pins, 3.5 mm long in thrums; style not seen in pins, 2.5 mm long in thrums, the branches clublike or linear. *Fruit* when dry ellipsoid to slightly obovoid, 4.5–5 mm long, 3.5–4 mm diam., drying dark red-brown; persistent calyx a minute beak; seed dorsal surface with 4 deep irregular longitudinal furrows, the ventral surface with 2 incompletely divided central plus 2 deep lateral longitudinal furrows.

Distribution (Fig. 28). Known only from the Caribbean coast of Panama just east of the Panama Canal in tropical moist forest with equatorial-tropical climate. This variety has been collected in flower in August and in fruit in October.

Additional specimens examined. PANAMA. SAN BLAS: trail E of Cangandí–Mandinga airport rd., 2–5 mi. S of Mandinga airport, 27 Oct. 1967 (fr), *Duke 14782* (MO, US).

The only flowering collection is of a thrum flower morph.

44d. **Psychotria panamensis** Standley var. **panamensis**. Figure 28.

Psychotria grandistipula Standley, J. Wash. Acad. Sci. 18: 276. 1928, not *Psychotria grandistipula* Merr., J. Asiat. Soc. Mal. 1: 42. 1923. TYPE of *P. grandistipula* Standl.: Costa Rica. San José: vic. Sta. María de Dota, ca. 1,600 m, 26 Dec. 1925 (fr), *Standley & Valerio 43268* (holotype, US).

Psychotria yunckeri Standley in Yuncker, Publ. Field Mus. Nat. Hist., Bot. Ser. 17: 397. 1938. TYPE: Honduras. Comayagua: nr. summit of range above El Achote, above plains of Siguatepeque, 1,850 m, 21 July 1936 (fl), *Yuncker et al. 6013* (holotype, F; isotypes, GH, K, MO).

Psychotria molinae Standley, Ceiba 1: 46. 1950. TYPE: Honduras. Francisco Morazán: drainage of Río Yeguare, 14°N, 87°W, 2,000 m, 20 Aug. 1946 (fl), *L. O. Williams & Molina 10390* (holotype, F—1264188; isotypes, F, GH).

Psychotria durilancifolia Dwyer, Ann. Missouri Bot. Gard. 67: 372. 1980. TYPE: Panama. Panamá: El Llano–Cartí Rd., vic. Gorgas Lab Mosquito Control Project site at km 12, 1 Aug. 1974 (fl), *Croat 26028* (holotype, MO—2240525).

Tree (2–)4–13 m tall; stipules sheathing, lanceolate, (10–)30–80 × (3.5–)5–7 mm, red-brown ciliate. *Leaves:* blades membranous to subcoriaceous, the base cuneate to subcordate, (7–)9–15(–22) × (2.5–)4–6(–10) cm, drying deep red-brown or sometimes green-brown; secondary veins (6–)8–16(–20) pairs, the axils lacking domatia or hairs or sometimes with segments of red-brown hairs along midvein and secondary veins below; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences:* panicle branched to 3–4 degrees; main axis (2.5–)5–9 cm long, the peduncle usually lacking, or 1.5–3 cm long; secondary axes in (4–)5–7(–8) ranks, the first-rank axes 2, (1–)2–6.5 cm long, the second-rank axes 2, (0.4–)1–3.5 cm long, the third-rank axes 2, (0.2–)0.6–2 cm long, the fourth-rank axes 2, (0.1–)0.2–1.5 cm long, the fifth-rank axes 2, 0.1–0.6 cm long, the sixth-rank axes 2, 0.4 cm long, the seventh-rank axes 2, 0.2 cm long, the eighth-rank axes 2, 0.1 cm long; cymes branched to 1–2 degrees. *Flowers:* corolla white, the tube 2–3 × 1.5–2 mm, the lobes lanceolate, 2–2.5 × 1 mm; stamens 5, the filaments 2.5–3 mm long in pins, 4–5 mm long in thrums; style 4–6 mm long in pins, 2.5 mm long in thrums, the branches spathulate. *Fruit* when dry ellipsoid, (6–)7–8 mm long, (4.5–)5.5–6.5(–7) mm diam., drying red-brown; persistent calyx usually a beak to 1 mm long; seed dorsal surface with 7–10 irregular longitudinal furrows, the ventral surface with 2 deep plus several irregular longitudinal furrows.

Distribution (Fig. 28). Continuous along the central cordillera from Veracruz, Mexico, to eastern Panama, at 200–2,100 m elevation, almost all above 500 m, in premontane to low montane wet forest to rainforest with usually equatorial to tropical-mountainous climate. It has been collected in flower throughout the year, primarily March–August, and in fruit throughout the year, primarily November–April.

Selected specimens examined. MEXICO. CHIAPAS: Mpio. Berriozábal, 13 km N of Berriozábal nr. Pozo Turipache and Finca El Suspiro, 1,000 m, 24 July 1972 (fr), *Breedlove 26311* (F, MEXU, MO); Mpio. VERAGUAS: rd. between Escuela Agricola Alto Piedra and Río Dos Bocas, ca. 10 km from escuela, 530–620 m, 26 July 1974 (fl), *Croat 25878* (DUKE, F—2 sheets, GH, MO, NY); "Cerro Tute" ridge up from former Escuela Agricola, Santa Fe, 8°35′N, 81°05′W, 800–1,000 m, 20 Feb. 1983 (fr), *Hamilton & Dressler 2986* (CR, MO); NW of Sante Fe, 1 km from Escuela Agricola Alto de Piedra, 24 Feb. 1975 (fr), *Mori & Kallunki 4785* (ENCB, MO).

The morphologies of *P. grandistipula* Standl., *P. yunckeri*, *P. molinae*, and *P. durilancifolia* fall well within the broad range of *P. panamensis* var. *panamensis*, so these former species are merged with var. *panamensis*.

Psychotria panamensis var. *panamensis* shows great variation within its range, including the following: leaves from Veraguas, Panama, are narrower and more coriaceous than those from elsewhere; leaves from Colón, Panama, are unusually large; secondary veins are more numerous in material from Guatemala, Honduras, and Colón and fewer in material from Chiapas, Mexico, and from Coclé, Panamá, and Veraguas provinces in Panama; secondary vein angle of divergence is greatest in leaves from Chiriquí, Panama; secondary veins are brochidodromous in Nicaraguan specimens; inflorescences are largest in specimens from Panama and Costa Rica; flowers are generally larger in Costa Rican material; and the corolla tubes from Honduras are narrowest (1.5 mm).

45. Psychotria sarapiquensis Standley, Publ. Field Mus. Nat. Hist., Bot. Ser. 18: 1360. 1938. TYPE: Costa Rica. Heredia: Vara Blanca de Sarapiquí, 1,500 m, July–Sep. 1937 (fl), *Skutch 3330* (holotype, US; isotypes, GH, K, MO). Figure 31.

Tree 2–10 m tall; young stems glabrous, the bark smooth; stipules sheathing, lanceolate, 11–45 × 2–5 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles (0.5–)1–2.5(–3.5) mm, glabrous, grooved above; blades membranous to subcoriaceous, oblanceolate to narrowly (or rarely broadly) elliptic to lanceolate, the apex short-acuminate, the base attenuate to cuneate, 6.5–15(–18) × 2–4.5(–8.5) cm, glabrous above and below, drying green-brown to red-brown; secondary veins 6–9(–11) pairs, diverging 30°–60°(–70°), eucamptodromous to brochidodromous, constantly arcuate to straight, prominulous below, glabrous, the axils lacking domatia or hairs; tertiary veins inconspicuous, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, panicles of cymes; panicle branched to 3–4 degrees; main axis (2–)5–13 cm long, the peduncle lacking or 3–4.5 cm long; secondary axes in (3–)4–5 ranks, the first-rank axes 2, (1–)1.5–5.5 cm long, the second-rank axes 2, (0.3–)1–2.5 cm long, the third-rank axes 2, (0.1–)0.5–1.4 cm long, the fourth-rank axes 2, 0.3–0.8 mm long, the fifth-rank axes 2, 0.1 mm long; cymes branched to 1–2 degrees; bracts not evident; bracteoles irregular, ca. 0.5 mm long, fringed. *Flowers* pedicellate, the pedicels 1–3 mm long; calyx often drying paler than the pedicel, cup-shaped, the tube 0.3–0.5 mm long, the lobes not evident, glabrous; corolla green-white, the tube cylindrical, 2.5–3 × 2 mm, white pubescent in throat, the lobes 5, lanceolate, 2–3.5 × 1.2 mm; stamens 5, the filaments 2.5–3 mm long in pins, 4 mm long in thrums, the anthers 1.2–1.5 mm long; style 4–4.5 mm long in pins, 2.5 mm long in thrums, the branches short. *Fruit* when dry ellipsoid to slightly obovoid, 7–8 mm long, 4–5.5 mm diam., maturing red, drying black to red-brown; persistent calyx often a minute beak; seed dorsal surface with 4–5 irregular often plus several shallow irregular longitudinal furrows, the ventral surface with 2 deep plus several shallow irregular longitudinal furrows.

Distribution (Fig. 31). Disjunct, occurring in Veracruz, Mexico, at 400–900 m elevation, and along the cordillera in Costa Rica and Panama, at 600–1,600 m, in tropical moist to premontane wet forest with equatorial-mountainous to usually tropical-equatorial climate. *Psychotria sarapiquensis* has been collected in flower in January, February, May, and August and in fruit July–March.

Selected specimens examined. MEXICO. VERACRUZ: Mpio. Catemaco, cerro al E de Coyame, 900 m, 13 Dec. 1971 (fr), *Beaman 5307* (MEXU); Estación de Biología Tropical Los Tuxtlas, 400 m, July 1975 (fr), *Chazaro 417* (ENCB, MEXU); Estación de Biología Tropical Los Tuxtlas, Cerro "El Vigia," 18 Mar. 1971 (fr), *Flores 50* (MEXU); Mpio. W of Santa Fe on rd. past Escuela Agricola Alto Piedra on Pacific side of divide, 800–1,200 m, 18 Mar. 1973 (fr), *Croat 23037* (MO); above Santa Fe on slopes of Cerro Tute, 1,200–1,400 m, 28 Sep. 1972 (early fr), *Gentry 6275* (F, GH, MO, NY); Alto Piedra, Santa Fe, 1,200 m, 27 Sep. 1972 (fr), *Lao 519* (MO); N of Santa Fe, 0–2 km N of Escuela Agricola Alto de Piedra, 16 Oct. 1974 (fr), *Mori & Kallunki 2510* (GH, MO); 16 Oct. 1974 (fr), *Mori & Kallunki 2519* (GH, MO); 18 Oct. 1974 (fr), *Mori & Kallunki 2638* (GH, MO); 26 Feb. 1975 (fl, fr), *Mori & Kallunki 4868* (MO—2 sheets); 29 Mar. 1975 (fr), *Mori & Kallunki 5325* (MO).

Psychotria sarapiquensis may be recognized by its usually narrow (length/width = 3) leaves with few (6–9[–11]) secondary veins and its large (7–8 mm long) ellipsoid to often obovoid fruit drying black or dark red-brown.

Mexican material is noteworthy for having lanceolate leaves with secondary veins diverging 60°–70°. Collections from the Fortuna and El Valle areas in Panama have large (to 18 cm long) broadly elliptic leaves with ca. 11 secondary veins, but they fit this species concept in other respects. Three of the Costa Rican collections—*Dryer 1539* (not cited above), *Skutch 3282*, and *Haber 531*—have subcoriaceous leaves drying red-brown and pedunculate inflorescences. *Psychotria sarapiquensis* is the most variable and/or the most problematic species in this treatment; it is conceivable that additional material from throughout its range will reveal it to be two or perhaps three different taxa.

46. Psychotria stockwellii C. Hamilton, Phytologia 64: 235. 1988. TYPE: Costa Rica. Alajuela: region of Zarcero, 1,800 m, 18 Oct. 1937 (fl, early fr), *A. Smith 543* (holotype, US; isotype, F). Figures 7i, 30.

Tree or shrub, (1–)2–10 m tall; young stems puberulent, the bark pale, ridged longitudinally; stipules sheathing, ovate, 9–15 × 3.5–9 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 0.5–2(–2.5) cm long, glabrous, terete; blades membranous, obovate or elliptic, the apex acuminate, the base attenuate, (8.5–)9–19 × (2–)3–7 cm, glabrous above and below, the midvein sometimes minutely puberulent below, drying dark brown above, slate brown or pale brown below; secondary veins (11–)14–17 pairs, diverging 60°–75°(–80°), eucamptodromous to sometimes brochidodromous, constantly arcuate, prominulous below, glabrous or minutely

puberulent below, the axils lacking domatia or hairs; tertiary veins conspicuous to evident, orthogonal reticulate. *Inflorescences* terminal or pseudoaxillary, spreading panicles of cymes (Fig. 7i); panicle branched to 3–4 degrees; main axis (7–)9–12 cm long, the peduncle (4–)5–9 cm long; secondary axes in 4–5 ranks, usually diverging over 90°, the first-rank axes 2, 1.8–5 cm long, the second-rank axes 2(4), 1–2.5 cm long, the shorter pair when present 0.4 cm long, the third-rank axes 2, 0.7–1.5 cm long, the fourth-rank axes 2, 0.4–0.6 cm long, the fifth-rank axes 2, 0.3 cm long; cymes branched to 1–2 degrees; bracts and bracteoles triangular, 0.5–2 mm long, ciliate. *Flowers* on pedicels 0.5–1.5 mm long; calyx cup-shaped, the tube 0.8 mm long, the lobes 5, triangular, often reflexed, 0.7 mm long, puberulent; corolla cream, the tube cylindrical, 4–5 × 1.5–2 mm, white pubescent in throat, minutely puberulent without, the lobes 5, ovate, 2 × 1 mm; stamens 5, the filaments 3.5–4 mm long in pins, 4.5–5.5 mm long in thrums, the anthers 1–1.2 mm long; style 6–7 mm long in pins, 3–4 mm long in thrums, the branches clublike or linear. *Fruit* when dry ellipsoid, 5–6 mm long, 4.5–5 mm diam., maturing red, drying dark red-brown; persistent calyx not evident or a beak or ring drying pale brown; seed dorsal surface with 6–10 irregular longitudinal furrows, the ventral surface with 2 deep regular plus sometimes several irregular longitudinal furrows.

Distribution (Fig. 30). Known from Alajuela, Costa Rica, and western Chiriquí, Panama, at 1,000–2,200 m elevation in regions of low montane rainforest with equatorial-mountainous climate. *Psychotria stockwellii* has been collected in flower January–October, primarily January–March, with immature fruit July–October, and in fruit January–March.

Additional specimens examined. COSTA RICA. ALAJUELA: region of Zarcero, 1,800 m, 18 Jan. 1937 (fl), *A. Smith 165* (F, MO). PANAMA. CHIRIQUÍ: Las Nubes, ca. 2,000 m, 7 Aug. 1974 (fl, early fr), *Croat 26450* (MO); Bajo Chorro, 1,800 m, 22 Jan. 1938 (fl), *Davidson 172* (F, MO); 2 Mar. 1938 (fl, fr), *M. Davidson 363* (A, F, MO); end of rd. to Bajo Mono, 21 Mar. 1977 (fl), *Folsom et al. 2250* (MO); E slopes of Cerro Pando, 8°55′N, 82°44′W, 2,000–2,300 m, 15 Oct. 1981 (fr), *Knapp 1646* (MO); vic. Las Nubes, 2.7 mi. NW of Río Chiriquí Viejo W of Cerro Punta, 2,200 m, 27 Feb. 1973 (fl, fr), *Liesner 293* (F, MO—2 sheets, NY); Las Nubes, 5 km NW of Cerro Punta, 1,800–1,950 m, 19 July 1975 (early fr), *Mori & Bolten 7240* (MO—2 sheets); Cerro Pando, nr. Panama–Costa Rica border, 2,000–2,482 m, 21 July 1975 (fl, early fr), *Mori & Bolten 7328* (MO, US); NW side of Cerro Punta beyond Las Nubes, 2,250 m, 15 Jan. 1971 (fl, fr), *Wilbur et al. 13211* (DUKE—2 sheets, MO); above San Ramón nr. Bajo Mono, 4 mi. NW of Boquete, 1,800 m, 22 Jan. 1971 (fl, fr), *Wilbur et al. 13544* (DUKE).

Psychotria stockwellii may be recognized readily by its inflorescence, whose secondary axes diverge over 90° from the main axis and whose tertiary axes diverge likewise from the secondary axes, and so forth, a character state unique in the subgenus. In addition, *P. stockwellii* differs from *P. panamensis* in having a larger corolla tube (4–5 vs. 2–3 mm long), long-pedunculate inflorescences, and conspicuous to evident (vs. inconspicuous) tertiary veins.

Reproductive organs at both levels are longer in the pin morph than in the thrum.

47. Psychotria trichotoma M. Martens & Galeotti, Bull. Acad. Roy. Sci. Bruxelles 11: 227. 1844. *Uragoga trichotoma* (M. Martens & Galeotti) Kuntze, Revis. Gen. Pl. 2: 963. 1891. TYPE: Mexico. Veracruz: Jalapa et Mirador, 900–1,200 m, Aug. 1840 (fl), *Galeotti 7092* (holotype, G, n.v., photo, MO). Figure 31.

Shrub or small tree 1.5–6 m tall; young stems glabrous or rarely minutely puberulent, the bark smooth or longitudinally furrowed; stipules sheathing, lanceolate, (10–)20–30 × 3–5 mm, glabrous, caducous, leaving a pale ridge with red-brown fringe. *Leaves* petiolate; petioles 1–4(–5.5) cm long, glabrous, flat above; blades membranous, ovate to elliptic, the apex acuminate, the base attenuate to cuneate, (10.5–)13–23(–26) × (5.5–)6.5–12(–15) cm, glabrous above and below, drying usually green-brown or sometimes red-brown, the veins usually drying paler; secondary veins (12–)14–18(–20) pairs, diverging 45°–60°, brochidodromous with secondary loops near margin, straight or sometimes slightly arcuate, elevated below, glabrous, the axils lacking domatia or hairs; tertiary veins evident to inconspicuous, orthogonal reticulate to percurrent. *Inflorescences* terminal or pseudoaxillary, panicles of cymes: panicle branched to 4–5 degrees; main axis (4–)7–16 cm long, the peduncle usually absent or 5–9 cm long; secondary axes in 5–7 ranks, the first-rank axes 2(4), equal, 4–8.5 cm long, the second-rank axes 2, 2–4.5 cm long, the third-rank axes 2, 1–3 cm long, the fourth-rank axes 2, 0.5–1.5 cm long, the fifth-rank axes 2, 0.2–1 cm long, the sixth-rank axes 2, 0.3–0.4 cm long, the seventh-rank axes 2, 0.2 cm long; cymes branched to (1)2 degrees; bracts and bracteoles not evident. *Flowers* pedicellate, the pedicels 0.5–1 mm long; calyx cup-shaped, the tube 0.2–0.5 mm long, the lobes (4)5, trian-

gular to barely evident, glabrous; corolla white, the tube cylindrical, 2.5 × 1.5 mm, white pubescent in throat, the lobes (4)5, lanceolate, 2–2.5 × 1 mm; stamens (4)5, the filaments 2–2.5 mm long in pins, 3–3.5 mm long in thrums, the anthers 0.8–1.3 mm long; style 4 mm long in pins, 2 mm long in thrums, the branches short. *Fruit* when dry obovoid, (5–)6–8 mm long, (4–)4.5–5.5 mm diam., maturing red, drying usually black or sometimes red-brown; persistent calyx inconspicuous or a broad beak ca. 0.5 mm long; seed dorsal surface with 4–5 irregular often plus several irregular shallow longitudinal furrows, the ventral surface with 2 deep regular and often 2–4 irregular longitudinal furrows.

Distribution (Fig. 31). Southern Mexico through Nicaragua, at 100–1,600 m elevation in regions of mostly evergreen forest with usually tropical-mountainous climate. *Psychotria trichotoma* occurs also in Venezuela and Ecuador. It has been collected in flower April–July and December–January, and in fruit throughout the year, primarily August–March.

The name *Psychotria trichotoma* has been used to misidentify specimens of most of the species in Group 6 plus *P. tenuifolia*, *P. limonensis*, *P. carthagenensis*, *P. quinqueradiata*, and *P. chagrensis*.

Psychotria trichotoma may be recognized by its fairly wide (length/width = 2) leaf blades drying usually green-brown with veins drying paler; secondaries usually 14–18 pairs, straight and making arches near margin; large inflorescences (usually 7–16 cm long) with no peduncle; and large (usually

6–8 mm long) obovoid fruit often drying black. The pedunculate inflorescences are found in some material from Oaxaca and Veracruz, Mexico, where the basal secondary axes may have been aborted. Specimens from Oaxaca show also minute puberulence on the inflorescence axes.

Reproductive organs at both levels are longer in the pin morph that in the thrum.

NEW SPECIES AND OTHER TAXONOMIC MATTERS IN THE NEW WORLD MEMECYLEAE (MELASTOMATACEAE)

Thomas Morley[1]

ABSTRACT

Four new species of *Mouriri* and one of *Votomita* are described and illustrated. *Mouriri coibensis* is reduced to a variety of *M. gleasoniana*. The relation of *Votomita* to *Mouriri* is discussed in the light of new information on seed structure; no change in generic boundaries is recommended for the present. Supplementary descriptions and drawings of *M. longifolia* and *V. pubescens* are provided.

Recent collections and older ones recently identified correctly to genus have yielded five new species of the tribe Memecyleae DC. (Melastomataceae). Four of these are members of the genus *Mouriri*: one from the Osa Peninsula of Costa Rica, one from western Venezuela in the state of Táchira, a third from southern Venezuela in Amazonas, and the fourth from northeastern Peru and adjacent Brazil. Also in *Mouriri*, new collections of *M. gleasoniana* from the Panama mainland, from Costa Rica, and from the island of Coiba revealed much intraspecific variation and require reassessment of the status of its close ally, *M. coibensis*. A recent flowering collection of *M. longifolia* permits the completion of its description and illustrations and allows its sectional placement. The fifth new species is a *Votomita* from Roraima of Brazil, the eighth known member of that small genus. The specimens of this species, as well as those of another collection of *V. pubescens*, bear ripe fruit, so that it is now possible to compare more accurately the seeds of *Votomita* and *Mouriri*. Previously, mature seeds were known only from *V. monantha* of Cuba. A discussion of ovule and seed structure and of generic relations therefore follows the description of *V. roraimensis*. More collections of *V. pubescens* make possible the completion of the descriptions and illustrations for that species.

References in the descriptions to the "type" of stomatal crypt refer to the forms described on pages 6 and 7 of Morley (1976).

Mouriri osaensis Morley, sp. nov. TYPE: Costa Rica. Peninsula de Osa, Llorona. Arbol común; solamente con frutos; con aprox. 7 m de alt. y 30 cm DAP. Madera pesada y muy resistente, usada para timones y ejes de carretas, macetas para pilar arroz, plumas o palancas etc., al rajarla al acha se va en capas y al quebrarla quedan chuzos muy punzantes. Nombre regional: *Huesillo & Quiebracho*. 19 Sep. 1975, *L. J. Poveda & Chrys y Adelaida Vaughan s.n.* (holotype, MIN). Figure 1.

Arbor usque 7 m alta trunco 30 cm diametro; petioli 3–5 mm longi; laminae grandes, basi rotundata usque truncata usque subcordata incisura usque 1 mm profunda; cryptae stomatophorae nullae; hypodermis absens; scleredes terminales foliorum irregulariter stellatae usque columnares; pedunculi ut videtur 1-flori, 1–3 in quoque later ad nodos aphyllos ramulorum 3.5–4 mm crassorum; fructus atropurpureus, globosus vel depresso-globosus, sine lobis; cicatrix hypanthii 7–11 mm diametro, 1.5–2 mm alto; loculi 2–5; semina 2–5.

Tree to 7 m tall and 30 cm in diam., glabrous except for the inflorescence; crown at times dense and elongate; young twigs terete or with 4 rounded angles; bark light gray, exfoliating in very small sheets; wood heavy and very resistant. Petioles 3–5 mm long; blades somewhat shiny on the face, 16–27 cm long, 5.6–9 cm wide, elliptic to ovate-elliptic or with an oblong tendency, abruptly acuminate at the apex, rounded to truncate to shallowly cordate at base, when cordate the notch to 1 mm deep; midrib grooved above at least in the lower half, prominent and rounded below; lateral nerves conspicuous when dry. Midrib xylem tubular, depressed in the center above; stomatal crypts none; upper epidermis mostly 1 cell thick but oc-

[1] Botany Department, 220 Bioscience Center, University of Minnesota, St. Paul, Minnesota 55108, U.S.A.

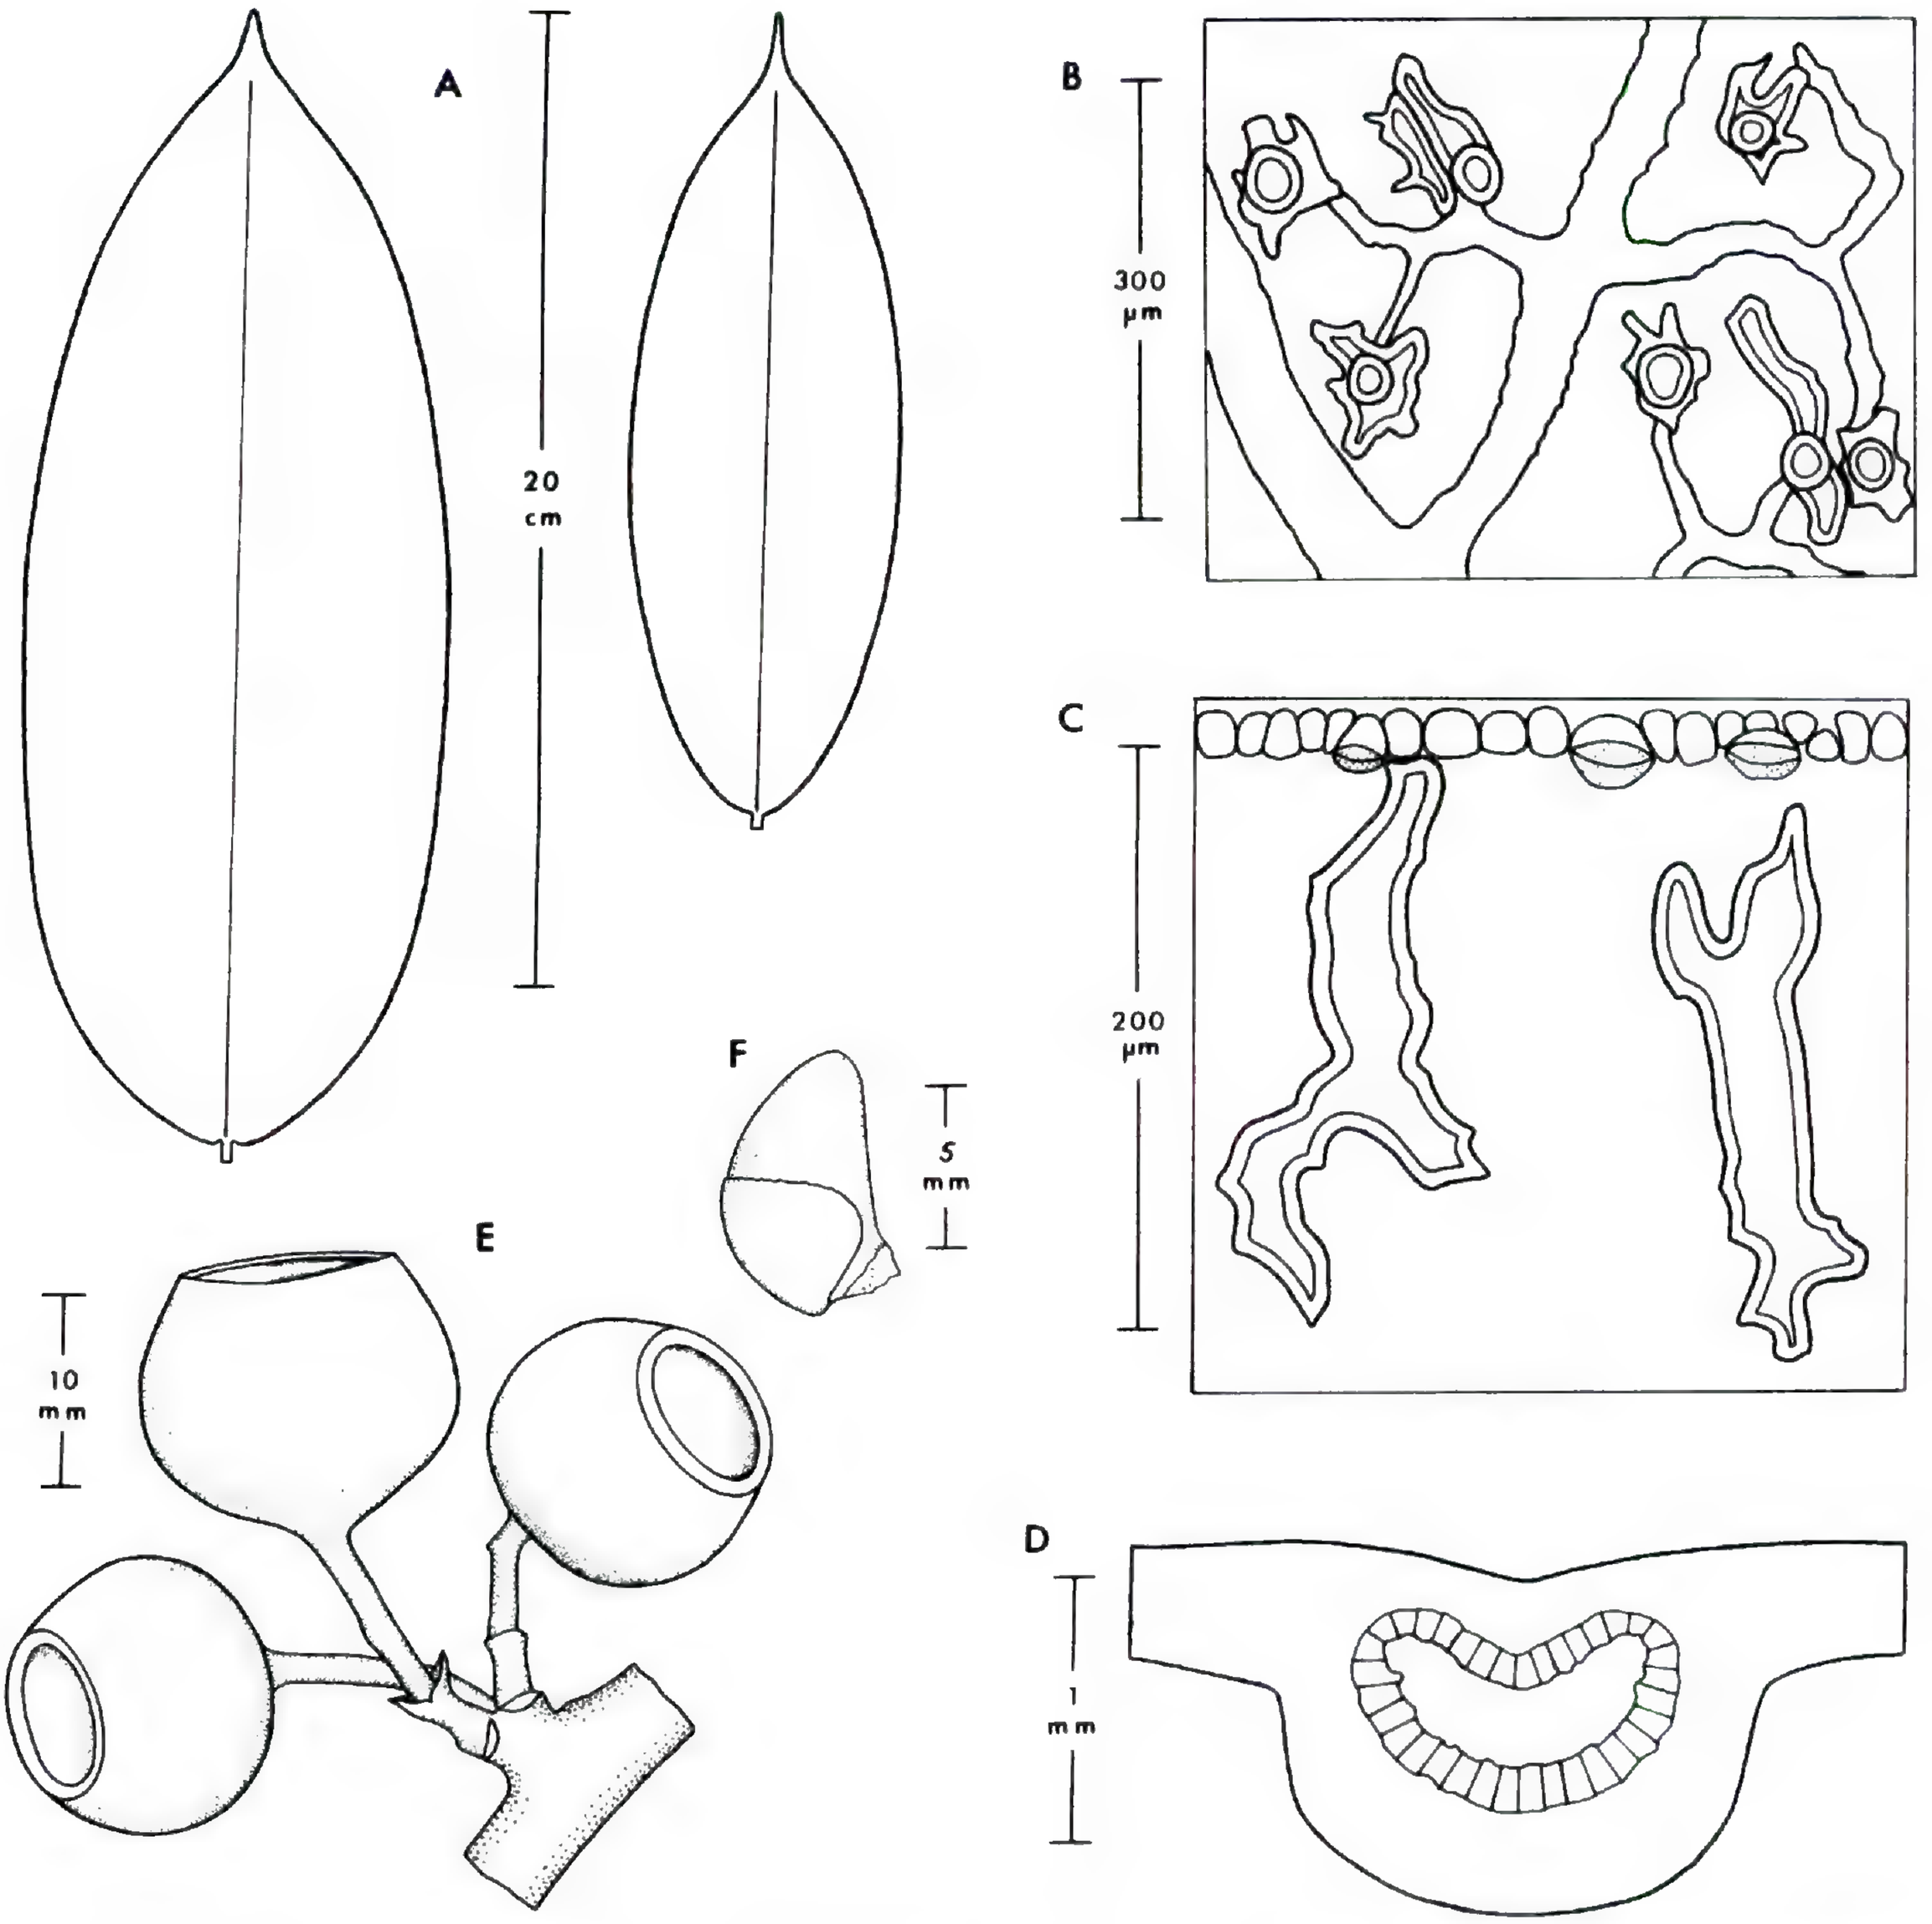

FIGURE 1. *Mouriri osaensis* (*Poveda & C. & A. Vaughan s.n.*).—A. Leaves.—B. Cleared portion of leaf blade showing veins and terminal sclereids.—C. Cross section of leaf blade showing sclereids and upper epidermis.—D. Cross section of leaf midrib.—E. Fruit cluster.—F. Seed (perhaps not fully mature).

casionally 2 cells thick at scattered places in the same leaf, mucilaginous walls occasional to frequent in the single cells and in the inner of the doubled cells; hypodermis none; terminal sclereids irregularly stellate with a strong columnar tendency, most with columnar arms, many entirely columnar. Flowers borne at leafless nodes of twigs 3.5–4 mm thick, in clusters of 1–3 per side, the peduncles 1-flowered, ca. 4.5 mm long to base of pedicel with 2 internodes in that length; bracts triangular, 2 mm long. True pedicels 7–9 mm long in fruit, very minutely puberulent. Flowers unknown. Fruits dark purple at maturity, globose to depressed-globose, not lobed, 12.2–16.5 mm high including hypanthium rim, 12–17 mm diam. when dry, bearing a circular rim of the circumscissile hypanthium 7–11 mm diam. and 1.5–2 mm high, 2–5-locular, 2–5-seeded. Seeds 8–8.7 mm high, 6.5–7.7 mm wide, 5–5.2 mm thick, irregularly ovoid, with a light brown slightly thickened portion 6–6.5 mm high in the lower half, the rest dark brown; hilum basal, whitish, rough, 1.5–3 × 3 mm.

Distribution. Known only from the type locality in the western part of the Osa Peninsula on the southwest coast of Costa Rica.

The new species appears to belong in subg. *Mouriri* sect. *Olisbea*. The characteristics suggesting this alignment are the large leaves, absence

of stomatal crypts, simple upper epidermis with mucilaginous walls, stellate terminal sclereids, and lack of a hypodermis. Within the section, the new species is closest to *M. completens*, on the basis of the former's similar leaves with a cordate tendency, very similar upper epidermis and foliar sclereids, and above all, the circumscissile hypanthium as seen on the fruit. The absence of flower characters of course detracts from understanding the relationships, but I still regard this alignment as reasonably certain. *Mouriri osaensis* differs from *M. completens* in leaf, fruit, and seed characters. The leaf blade is less cordate than in *M. completens*; the fruit is purple instead of greenish, lacks a broad stipe at base, and is not abruptly narrowed to the hypanthium at the apex, nor is it lobed according to the seed number; the hypanthium on the fruit is 7–11 mm in diameter rather than 4.5–7 as in *M. completens* and is only 1.5–2 mm deep instead of 3.8–4.5 mm. The seeds are a bit smaller and differ in shape, best compared in the illustrations.

Mouriri papillosa Morley, sp. nov. TYPE: Venezuela. Táchira: 10 airline km E of La Fundación, 13–23 km by road, around Represa Dorada, primary evergreen forest with patches of secondary vegetation. Soils tending to be sandy, derived from metamorphic rock (schist or gneiss), 600–900 m, 7°47–48′N, 71°46–47′W, 4 m tree, petals and anthers pinkish. 30 Apr. 1981, *R. Liesner & M. Guariglia 11616* (holotype, US; isotypes, MIN, MO). Figure 2.

Arbor usque 15 m alta; laminae 4.7–11.5 cm longae, 2.3–5.5 cm altae, elliptico-ovatae usque ellipticae, basi truncata vel subcordata; pagina inferior costae mediae rotundata ad basem, 2-angulata ¼–½ distantiae versus apicem; cryptae stomatophorae Typi II, tecto saepe depresso; epidermis supera stratiis 2–3 cellularum, cellulae interiorae plerumque parietibus mucilaginis aureis, parietes lamellis 5–9; calyx ovarium inferum includens 6–7 mm longus, ovarium papillosum; calyx 1.4–1.8 mm findens inter lobos sub anthesi; antherae 3.6–4 mm longae; ovarium 4–5-loculare; ovula 12–16.

Tree to 15 m high, glabrous except for the inflorescence; young twigs terete to 2-channeled to 4-angled. Petioles 1.5–3 mm long; blades 4.7–11.5 cm long, 2.3–5.5 cm wide, elliptic-ovate to seldom elliptic, abruptly short- to medium-acuminate at apex, rounded to a truncate or slightly cordate base, the basal notch up to 1 mm deep; midrib plane above, prominent below, rounded at base, becoming 2-angled ¼–½ of the way to the apex, then becoming plane near the apex; lateral nerves slightly visible above and below when dry. Midrib xylem tubular; stomatal crypts Type II, averaging in a leaf ca. 45 μm diam., 35 μm high, 57 per mm² (extremes 35–55 μm diam., 30–40 μm high, 45–69 per mm²), the roof often depressed in the center; upper epidermis 2 or 3 cells thick, the upper 1 or 2 layers without mucilaginous walls, the cells of the inner layer mostly with golden mucilaginous walls ⅓–¾ the height of the cell and containing 5–9 lamellae, these cells enlarged and together resembling a hypodermis, aligned or not with the cells of the outer layers; terminal sclereids stellate-columnar, crowded. Inflorescences in the lower leaf axils and at leafless nodes of twigs up to 5 mm thick, 1–3 per side, each 1–3-flowered, 1.5–3.5 mm long to base of farthest pedicel measured along the axes with 2 internodes in that length, the internodes very minutely puberulent; bracts 1–1.5 mm long, ovate-triangular, often deciduous by anthesis. True pedicels 1–4 mm long; calyx including inferior ovary 6–7 mm long, campanulate, it and the pedicels very minutely puberulent, the ovary papillose, the papillae enlarging into rounded wartlike bumps crowded on the immature fruit; free hypanthium 2.5–2.8 mm long; calyx lobes before anthesis low-triangular, 0.7–0.8 mm long, 2–2.1 mm wide, 1.8–2.4(–2.8) mm long when measured from the stamen attachment, the calyx splitting between the lobes at anthesis a distance of 1.4–1.8 mm. Petals pinkish, 5.5–6 mm long, 5.5–6 mm wide, triangular, erose, clawed at base. Mature filament length unknown; anthers pinkish, 3.6–4 mm long; thecae 3–3.5 mm long, dehiscing by apical slits; gland 0.4–0.6 mm long, 2.6–2.9 mm from apex of anther when measured from center of gland; cauda ca. 0.45 mm long, scarcely noticeable externally. Ovary 4–5-locular; ovules axile-basal, produced only outwardly from each placenta, 12–16 in all; style ca. 15 mm long. Persistent calyx red on immature green fruit. Ripe fruit and seed unknown.

Paratype. VENEZUELA. TÁCHIRA: Distr. Uribante. In forest along road from La Siberia to entrance to Las Cuevas Represa. Evergreen forest with much bamboo and *Scleria secans*, ±1,100 m (immature fr), 8 July 1983, *H. van der Werff & A. González 5123* (US, MO).

Distribution. Evergreen forests of far western Venezuela in south-central Táchira State SE of San Cristóbal at 600–1,100 m.

This species is best placed in the sect. *Mouriri* (Morley, 1976: 36) on the basis of its tubular midrib xylem, small Type II stomatal crypts, hypodermis, acuminate leaf apex, axile-basal placentation, and relatively short thecae. Section *Litophyllum* is very similar, differing only in its lack of a hypoderms. The hypodermis of sect. *Mouriri*

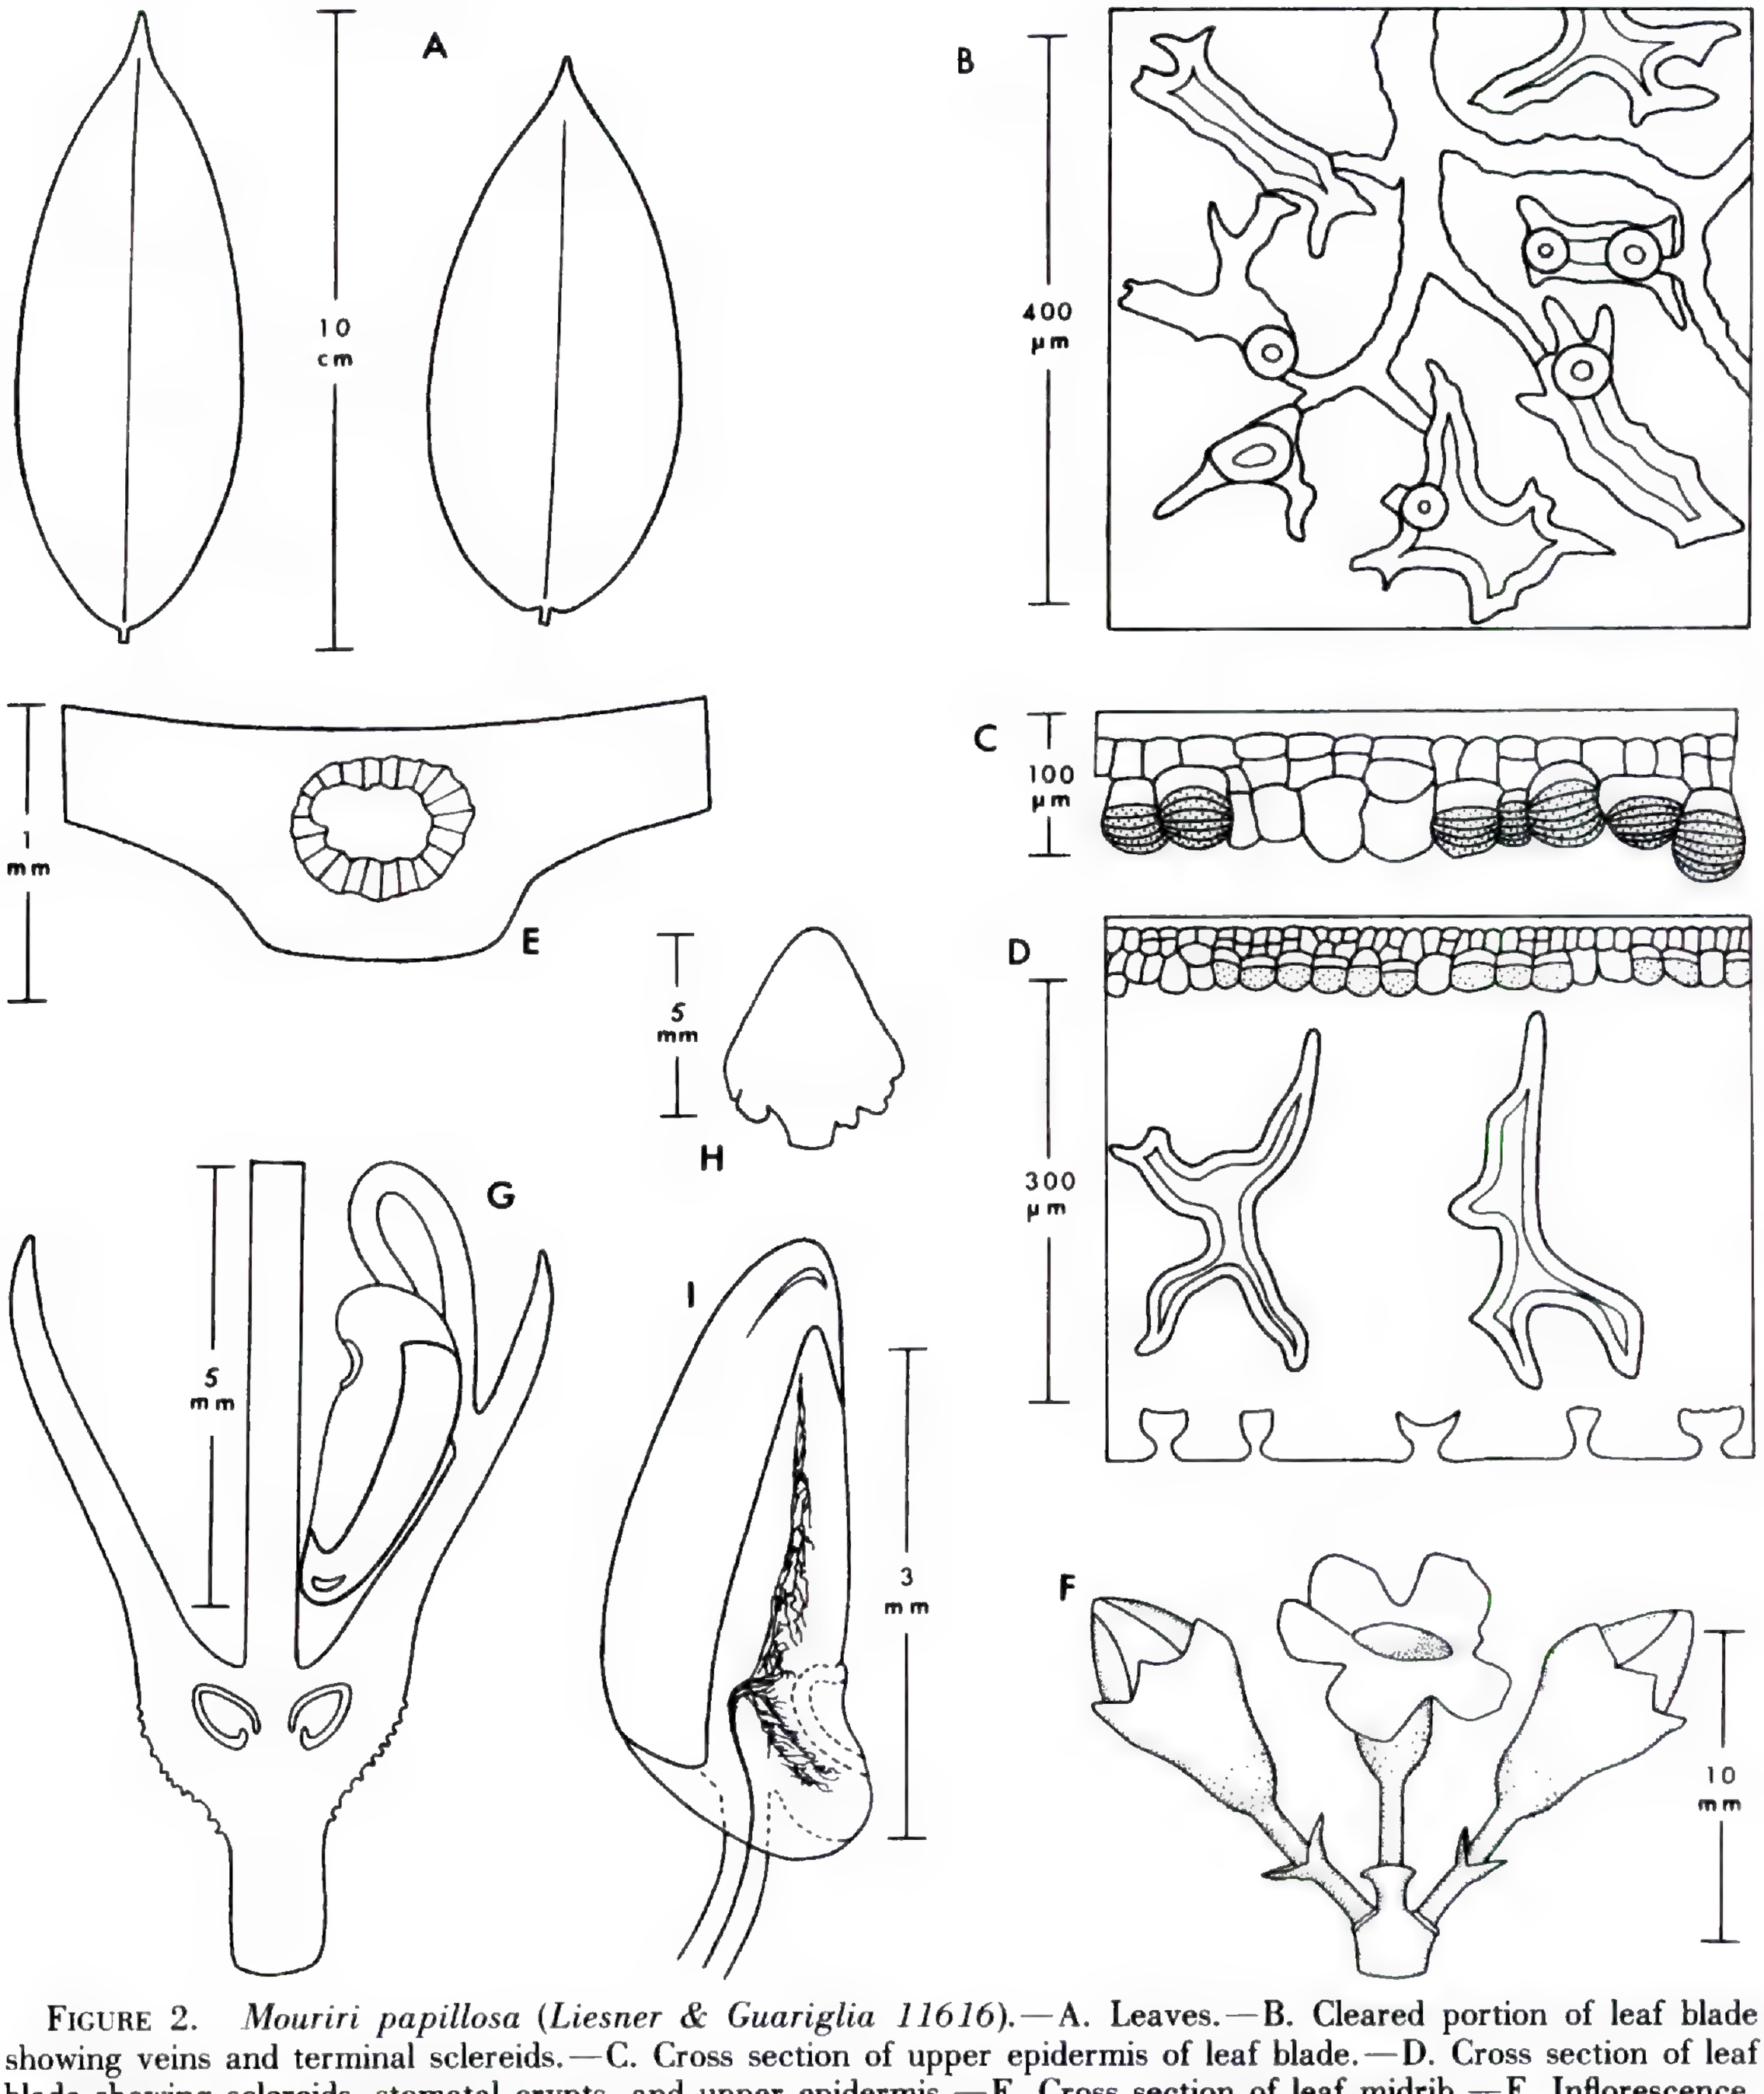

FIGURE 2. *Mouriri papillosa* (*Liesner & Guariglia 11616*).—A. Leaves.—B. Cleared portion of leaf blade showing veins and terminal sclereids.—C. Cross section of upper epidermis of leaf blade.—D. Cross section of leaf blade showing sclereids, stomatal crypts, and upper epidermis.—E. Cross section of leaf midrib.—F. Inflorescence.—G. Longisection of flower before anthesis.—H. Petal.—I. Anther, shown cleared except for the thecae.

appears to be derived from the inner layer of a double or triple epidermis, judging by the presence in its cells of mucilage walls and the occasional alignment of the hypodermal cells with cells or groups of cells in the epidermis. In *M. papillosa* the alignment is rather frequent, as seen in section view; however, as seen in face view, the cells are most often unaligned. Thus the inner layer of cells appears to be sufficiently modified to justify considering it a hypodermis like those of the other species of sect. *Mouriri*, and not simply as the inner layer of a multiple epidermis.

Section *Mouriri* contains three species in addition to *Mouriri papillosa*: *M. guianensis*, *M. domingensis*, and *M. barinensis*. From all three, *M. papillosa* differs in having a papillose ovary, a larger ovary plus calyx, and a longer free hypanthium, anthers, thecae, and splitting distance

between calyx lobes. It further differs from *M. barinensis* in having short petioles.

The curious multiple lamellations in the mucilage walls of *M. papillosa* I have noted elsewhere only in two collections of *M. barinensis*. Since this character varies in the latter species, it is possible that it will also prove to be a variable in *M. papillosa*.

Although plants of sect. *Litophyllum* lack a hypodermis, in other respects some of them resemble rather closely the members of sect. *Mouriri*. Most similar is *M. gleasoniana*, including its var. *coibensis*. From this, *M. papillosa* differs in its lack of a two-winged lower midrib and in its papillose ovary and longer ovary plus calyx, longer anthers and thecae, and greater splitting distance between the calyx lobes.

Mouriri latihila Morley, sp. nov. TYPE: Venezuela. Amazonas: Selva alta pluvial, a 7–9 km de Yavita hacia Pimichín, lat. 2°55′N, long. 67°25–30′W. Altura: 125 metros. Tree 3 m tall; leaves subchartaceous, dark green above, pale green below; fruit orange red. 22 Apr. 1970, *Julian A. Steyermark & George Bunting 102927* (holotype, VEN; isotype, MICH). Figure 3.

Arbor 3 m alta; cryptae stomatophorae Typi II; epidermis supera strata uno cellularum; sclerides terminales foliorum plerumque columnares; flores tetrameri, axillares, solitarii; calyx omnino clausus usque ad anthesem, tum ad lineas conjunctionis loborum rumpens; semen 1, lateribus 2, hilum latissimum, partem majoram lateris uni seminis occupans.

Tree 3 m high, glabrous; young twigs narrowly 4-winged. Leaves subchartaceous, dark green above, pale green below; petioles 1–2.5 mm long; blades 6.5–11.5 cm long, 3.3–5.7 cm wide, ovate-elliptic or ovate-oblong to ovate, abruptly acute to abruptly acuminate at apex, broadly acute to broadly rounded at base; midrib slightly grooved above, prominent and rounded below; lateral nerves prominent above and below when dry. Midrib xylem tubular; stomatal crypts Type II, averaging in a leaf ca. 55 μm diam., 31 μm high, 50 per mm² (extremes 40–75 μm diam., 25–38 μm high, 33–66 per mm²); upper epidermis 1 cell thick, the cells with mucilage walls ⅔–¾ of the cell height; hypodermis none; upper palisade layer clear, not filled with tannin compounds, but most of the other mesophyll cells so filled; terminal sclereids mostly columnar, narrow, often slanting and weaving somewhat, sometimes branching in the spongy parenchyma, the ends there sometimes horizontal. Flowers single in the leaf axils, borne on peduncles 0.2–1 mm long bearing 2–3 pairs of bracts, the bracts 0.7–1.2 mm long, triangular. True pedicels 0.5–1.3 mm long; flowers tetramerous; calyx including inferior ovary 3 mm long when immature, mature length unknown, ellipsoid or slightly obovoid, conical at each end; calyx lobes fused to the apex of the flower in bud, splitting apart regularly at anthesis, each then triangular and acute, 1.8–2.4 mm long, 1.2–1.4 mm wide, 2–2.4 mm long when measured from the stamen attachment; free hypanthium ca. 1 mm long. Petals, stamens, and ovary at anthesis unknown. Fruit orange-red, depressed-globose, ca. 9 mm long, 12 mm diam., bearing the calyx lobes and the remains of the style. Seed 1, ca. 7.5 mm high, 10.5 mm wide, 4.6 mm thick, oblongish with an apical notch as seen in face view, one face and most of the edges with polished surfaces, these curved over onto the opposite side at 4 places, 2 above, 2 below, the irregularly roughened hilum occupying most of the opposite side of the seed.

Distribution. Known only from the type locality in tropical rainforest near the west-central border of Amazonas, Venezuela, between the headwaters of the Guainía and Atabapo rivers.

Mouriri latihila clearly falls within subg. *Mouriri* on the basis of its tubular midrib xylem and its seed with a large polished area. The new species is very distinctive, standing apart on the combination of its tetramery, closed calyx, and small Type II stomatal crypts. Its sectional relation is uncertain; it is here placed tentatively in sect. *Litophyllum* because of its tubular midrib xylem, small crypts, leaf shape, small flower, and lack of a hypodermis (Morley, 1976: 36). When placed here, it weakens further the already weak sectional boundaries. From this position the new species appears to have ties with sect. *Megacrypta*, whose two species also have tetramery, closed calyces, and columnar sclereids. The new plant differs widely from these two, however, in its much smaller leaves and small Type II stomatal crypts, as well as in its shorter pedicels and calyces. Within sect. *Litophyllum*, no species appear very similar to *M. latihila*, although two are tetramerous and have short one-flowered peduncles like the new species: *M. exadenia* and *M. lancifolia*. *Mouriri latihila* differs from *M. exadenia* in having Type II crypts, columnar sclereids, a closed calyx, and a different seed shape; from *M. lancifolia* it differs in its broader leaves, presence of stomatal crypts, columnar sclereids, and closed calyx.

Mouriri retentipetala Morley, sp. nov. TYPE: Brazil. Amazonas: Rio Javari, behind Palmei-

ondary and smaller nerves prominent above and below when dry. Midrib xylem tubular; stomatal crypts Type II, averaging in a leaf 31–50 μm diam., 18–25 μm high, 27–54 per mm²; superficial stomata numerous; upper epidermis 1 cell thick, nearly all the cells with thick mucilaginous walls; hypodermis none; terminal sclereids stellate, the central body sometimes isodiametric with 4–5 arms, more often 2–6 times as long as wide with 1–3 large arms. Flowers tetramerous, single in the leaf axils on sessile pedicels 2–2.5 mm long with 1 or 2 pairs of ovate-triangular bracts 1–1.6 mm long at base of pedicel. Calyx including inferior ovary 2.5–3.4 mm long, campanulate, the surface scattered-mealy with loose inflated hairs, these white on the outer surface of the calyx lobes, golden on the inner surface; free hypanthium ca. 0.7 mm long; calyx lobes 0.2–0.4 mm long, 1.1–1.4 mm wide, broadly triangular or slightly apiculate, splitting apart a distance of 0.5–0.7 mm at anthesis. Petals protruding from the calyx early in the bud, narrowly ovate-elliptic, 3–3.6 mm long, 1.1–1.5 mm wide, minutely glandular-hairy mostly on the apical third, persistent on the unripe fruit. Antesepalous filaments 1.2–1.4 mm long, antepetalous ones 1.7–1.9 mm long; anthers 1.6–2.2 mm long; thecae 0.9–1.2 mm long, dehiscing by a single apical pore; gland none; cauda 0.8–1 mm long. Ovary 1-locular with 4 ovules arranged around a short central and basal placenta; style ca. 5 mm long, sharply curved at tip, with a sharply demarcated 4-lobed stigma. Fruits subglobose, ca. 6.5–7.5 mm high, 8–9 mm thick, crowned with the persistent calyx. Seed 1, ca. 5.5–5.8 mm high, 7–7.5 mm wide, 4–5 mm thick, medium brown and polished except for a basal hilum as wide as the seed, the funiculus visible as a hardened and polished irregular stalk extending below the main polished part of the seed.

Paratype. PERU. LORETO: Arboreti Jenaro Herrera (Amazoniae Peruvianae, Prov. Requena, ad flumen Ucayali, silva uda aequinotiali, 73°45′W, 4°55′S, ca. 120 m alt.). Specimina lecta vel selecta praecipue a *Luciano Bernardi* illuc misso a COTESU (Cooperation Technique Suisse) VIII–IX. 1976. 6-R-83 (Parcela Marmillod) (G).

Distribution. Tropical forests in the drainages of the Ucayali and Javari rivers in NE Peru and adjacent Brazil at about the latitude of Requena, Peru.

This species, like the foregoing one, falls in subg. *Mouriri*, its tubular midrib xylem, anatropous ovules, and polished seed being the determining features. The tetramery, monoporous and eglandular anthers, and persistent petals of this entity make it very distinctive. This is only the second species of the genus to be found with monoporous anthers, and persistent petals have not been noted before. The petals were persistent on the green but nearly ripe fruits of the type collection; they were gone from the ripe fruit of the paratype. It is impossible to know if they had dropped naturally or were broken off during collection in the latter case. Within its subgenus the new species is most similar to three species in sect. *Litophyllum*: *M. exadenia*, *M. latihila*, and *M. monopora*. Probably *M. retentipetala* is most closely related to these three and belongs with them in sect. *Litophyllum*.

The characteristics of *M. retentipetala* suggesting the three species named are: small simple stomatal crypts, a one-layered upper epidermis, small flowers, tetramery, monoporous eglandular anthers, a one-locular ovary with few ovules, and a large hilum on the seed. Some of these characters are not found in all three of the presumed allies, and several have not yet been investigated in *M. latihila* owing to lack of material.

Mouriri retentipetala differs from *M. exadenia* in having higher, more numerous stomatal crypts, pedicellate flowers, persistent petals, monoporous caudate anthers, and a large hilum on the seed. From *M. monopora* the new species departs in its tetramery, triangular calyx lobes, and eglandular anthers with a longer cauda and straight thecae. From *M. latihila*, *M. retentipetala* varies in having stellate foliar sclereids, short calyx lobes so that the petals protrude from the calyx early in the bud, and persistent petals.

Mouriri gleasoniana Standley ex Standley & Steyermark var. **coibensis** (Morley) Morley. *Mouriri coibensis* Morley, Fl. Neotropica 15: 143–145. 1976.

Recent collections of *M. gleasoniana* from Costa Rica and Panama require reassessment of the status of *M. coibensis*, a close relative of the former species from the island of Coiba off the southwest coast of Panama. When *M. coibensis* was described, *M. gleasoniana* was known only from Honduras to Mexico, and the differences between the two taxa as then known were sharp. The new material partly bridges the gap between them and seriously weakens their separation. I believe realities are best served by viewing both as part of a single variable species. As presently known, the island plants are still distinguishable and are retained as a variety. Six major variables are involved, as shown in Table 1. Plants of the complex are yet to be found in Nicaragua.

TABLE 1. Geographic variation in six characters of *Mouriri gleasoniana*.

			Anthers			
	Foliar Sclereids	Stomatal Crypts	Theca Length (mm)	Gland Length (mm)	Distance from Theca Base to Anther Base on Gland Side (mm)	Ovule Numbers
Central Panama	roundish	Type II	2.7–3.0	0.8–0.9	1.0–1.2	29–33
Coiba Island	roundish	mostly Type III	1.9–2.2	0.2–0.5	1.2–1.4	18–20
Northeastern Costa Rica	roundish to columnar	mostly Type II	2.2–2.7	0.5–0.7	0.9–1.2	23–33
Honduras–Mexico	columnar tendency	mostly Type II	2.0–3.0	0.4–0.9	0.7–0.8	15–24

Ovule numbers are relatively large in plants of Costa Rica and the Panama mainland. In the one flowering collection from Panama (*Knapp & Huft 4424*) and one of the two Costa Rican collections (*Hammel 9317*), the large number of ovules apparently results in an unusual placentation in that the ovules in each locule are arranged on all sides of the axile-basal placenta. These are the only known examples of such an arrangement in sections 4 through 9 of subg. *Mouriri*.

A transition from a large number of ovules to a small one raises the question of which state, if either, represents the primitive condition. A similar trend was found in *M. guianensis*, where the conclusion was that the greater number was primitive (Morley, 1983). In *M. gleasoniana* the presence of the larger numbers close to South America, where the genus appears to have originated, with the smaller numbers to the north, where the environment gradually becomes more extreme, suggests that the same interpretation should be made in this species. Throughout the range, the fruits are 1–4(–5)-seeded; as in *M. guianensis*, many ovules must therefore abort when a large number is present before fertilization. Accordingly, those plants with fewer ovules in the flower and thus less wastage would be regarded as better adapted and, in this case, more specialized. It would appear that in increasingly extreme environments the demand for floral economy becomes greater.

Mouriri longifolia (HBK) Morley. Until recently, this species was known only from fruiting material. A flowering collection has now been made, so that the following addendum to the description of the species can be given, with illustrations (Fig. 5).

Inflorescences at leafless nodes of twigs 4–7 mm thick, 1 or 2 per side, each 1–5-flowered, 2.5–7.7 mm long to base of farthest pedicel measuring along the axes and with 2 or 3 internodes in that length; bracts 1.4–2.5 mm long, triangular or narrowly so, mostly present at anthesis, deciduous later. Axes of inflorescence, ovary, and calyx minutely puberulent. True pedicels 7–15 mm long; calyx including inferior ovary 6.2–8.5 mm long, campanulate; free hypanthium 2.2–2.7 mm long; calyx lobes just before anthesis 2.1–2.4 mm long, 2.5–3 mm wide, 3.8–4.1 mm long from the stamen attachment, triangular with inverse-curved sides, the calyx splitting 0–0.5 mm between the lobes at anthesis. Petals ovate-oblong, ca. 10 mm long including a basal claw ca. 3 mm long, 7 mm wide, broadly acute at apex, erose toward the base. Filaments 11–14 mm long; anthers 3–3.3 mm long; thecae 2.8–3 mm long, dehiscing by apical slits; gland 0.8–1 mm long, 2.1–2.3 mm from apex of anther when measured from center of gland; cauda 0.6–0.8 mm long. Ovary 5-locular; placentae basal in each locule, the ovules borne on all sides of a short basal column, ca. 5 per placenta, ca. 25 in all; style 17–22 mm long.

With the flowering material in hand it now becomes apparent that *M. longifolia* belongs in sect. *Apirangia*. Specifically, the characters that place it there are the tubular midrib xylem, filiform sclereids, Type III crypts like those of *M. apiranga*, the lack of a hypodermis, the free calyx lobes with the petals protruding from them early in the bud, the anther shape which generally agrees with that of the other species, the proximate position of the placentae which are not widely separated, and the position of the ovules on all sides of each placenta.

Additional collections examined. VENEZUELA. AMAZONAS: Estación Experimental de Sta. Bárbara del Orinoco, 1–2 km al sur de Trapichote, 26 Feb.–2 Mar. 1976 (st), *Berry & Chesney 2083* (US); 28 Mar. 1976 (defl.), *Berry & Chesney 2179* (US); Tayari, 1 Nov. 1975 (fl), *Lissot s.n.* (US).

Votomita roraimensis Morley, sp. nov. TYPE: Brazil. Roraima: BR 174, Manaus–Caracaraí, km 523, 1°20′N, 60°43′W. In damp water-logged woodland. Straggling tree to 5 m, 2 June 1986, *Hopkins, Pereira de Lima, Guedes de Oliveira & Lowy 502* (holotype, INPA; isotypes, K, MIN, NY, US). Figure 6.

Arbor usque 5 m alta; costa media folii subta lateribus papillosa; cryptae stomatophorae unaquaeque cavitatibus 2–5; ovarium 4-loculare placentis axialibus; ovula 3–4 undique circum quamque placentam genita, in recta verticilla; fructus 6.7–9.5 mm diametro, stylo persistenti; semen 1, vitta angusta laeve ⅔ circumdatum.

Tree to 5 m, glabrous except for the leaf midrib; young twigs terete. Petioles 1.5–2.5 mm long; blades 6.1–10.2 cm long, 2.3–4 cm wide, elliptic to elliptic-ovate, acuminate at the apex, medium acute at base; midrib flat to slightly rounded above, narrowly winged below for its length, the sides with papillae 20–35 μm long; lateral nerves not visible above or below when dry. Midrib xylem tubular; stomatal crypts multiple, each branched above the mouth into 2–5 small cavities, with prominent papillae on the central roof, the multiples 60–125 μm total diam., 55–75 μm high, averaging ca. 28 per mm²; upper epidermis mostly 1(2) cell(s) thick, a deep hypodermis present with walls tending to align with the epidermal cells above, the hypoderm cells commonly with mucilaginous walls; foliar sclereids terminal, thick-columnar with large dendroid branches at each end. Peduncles terminal and at leafless nodes of twigs up to 5 mm thick, 1–2 per side, 1-flowered, 2–11 mm long to base of farthest pedicel including 1 or 2 internodes; bracts narrowly triangular, 0.7 mm long, deciduous before anthesis. True pedicels 3–5 mm long; flowers 4-merous; calyx including inferior ovary ca. 4.5 mm long, campanulate; calyx lobes 0.4 mm long, 1.4 mm wide, rounded-triangular and mucronulate, stretching and splitting irregularly between lobes as bud enlarges. Immature petals ovate, sessile, 4.7 mm long, 2 mm wide. Stamens lightly connate in the lower third, 2.9–4.2 mm long; filaments 0.3–0.4 mm long; anthers 2.6–2.8 mm long; thecae 1.2–1.3 mm long; gland terminal, concave, 0.6–0.7 mm long, Ovary 4-locular with axile placentation, each locule with 3–4 ovules in a vertical whorl, the ovules 15–16 in all; style 6 mm long. Fruit medium brown when dry, spheroid with persistent style, 7–9.3 mm high excluding style and calyx, 7.7–9.4 mm wide, 6.7–8.9 mm thick. Seed 1, spheroid, light brown with dark brown markings, 5.9–6.8 mm high, 7.4–8.2 mm wide, 7–7.9 mm thick, with a narrow, smooth but unpolished tan band encircling ⅔ of the seed, extending from a small projection near the broken chalazal vascular strand where the band is narrowest to the micropylar end where it is widest, the width here 2.7–3 mm; remainder of surface rugose.

Distribution. Known only from the type locality in tropical forest in SW central Roraima, Brazil, east of the Rio Branco.

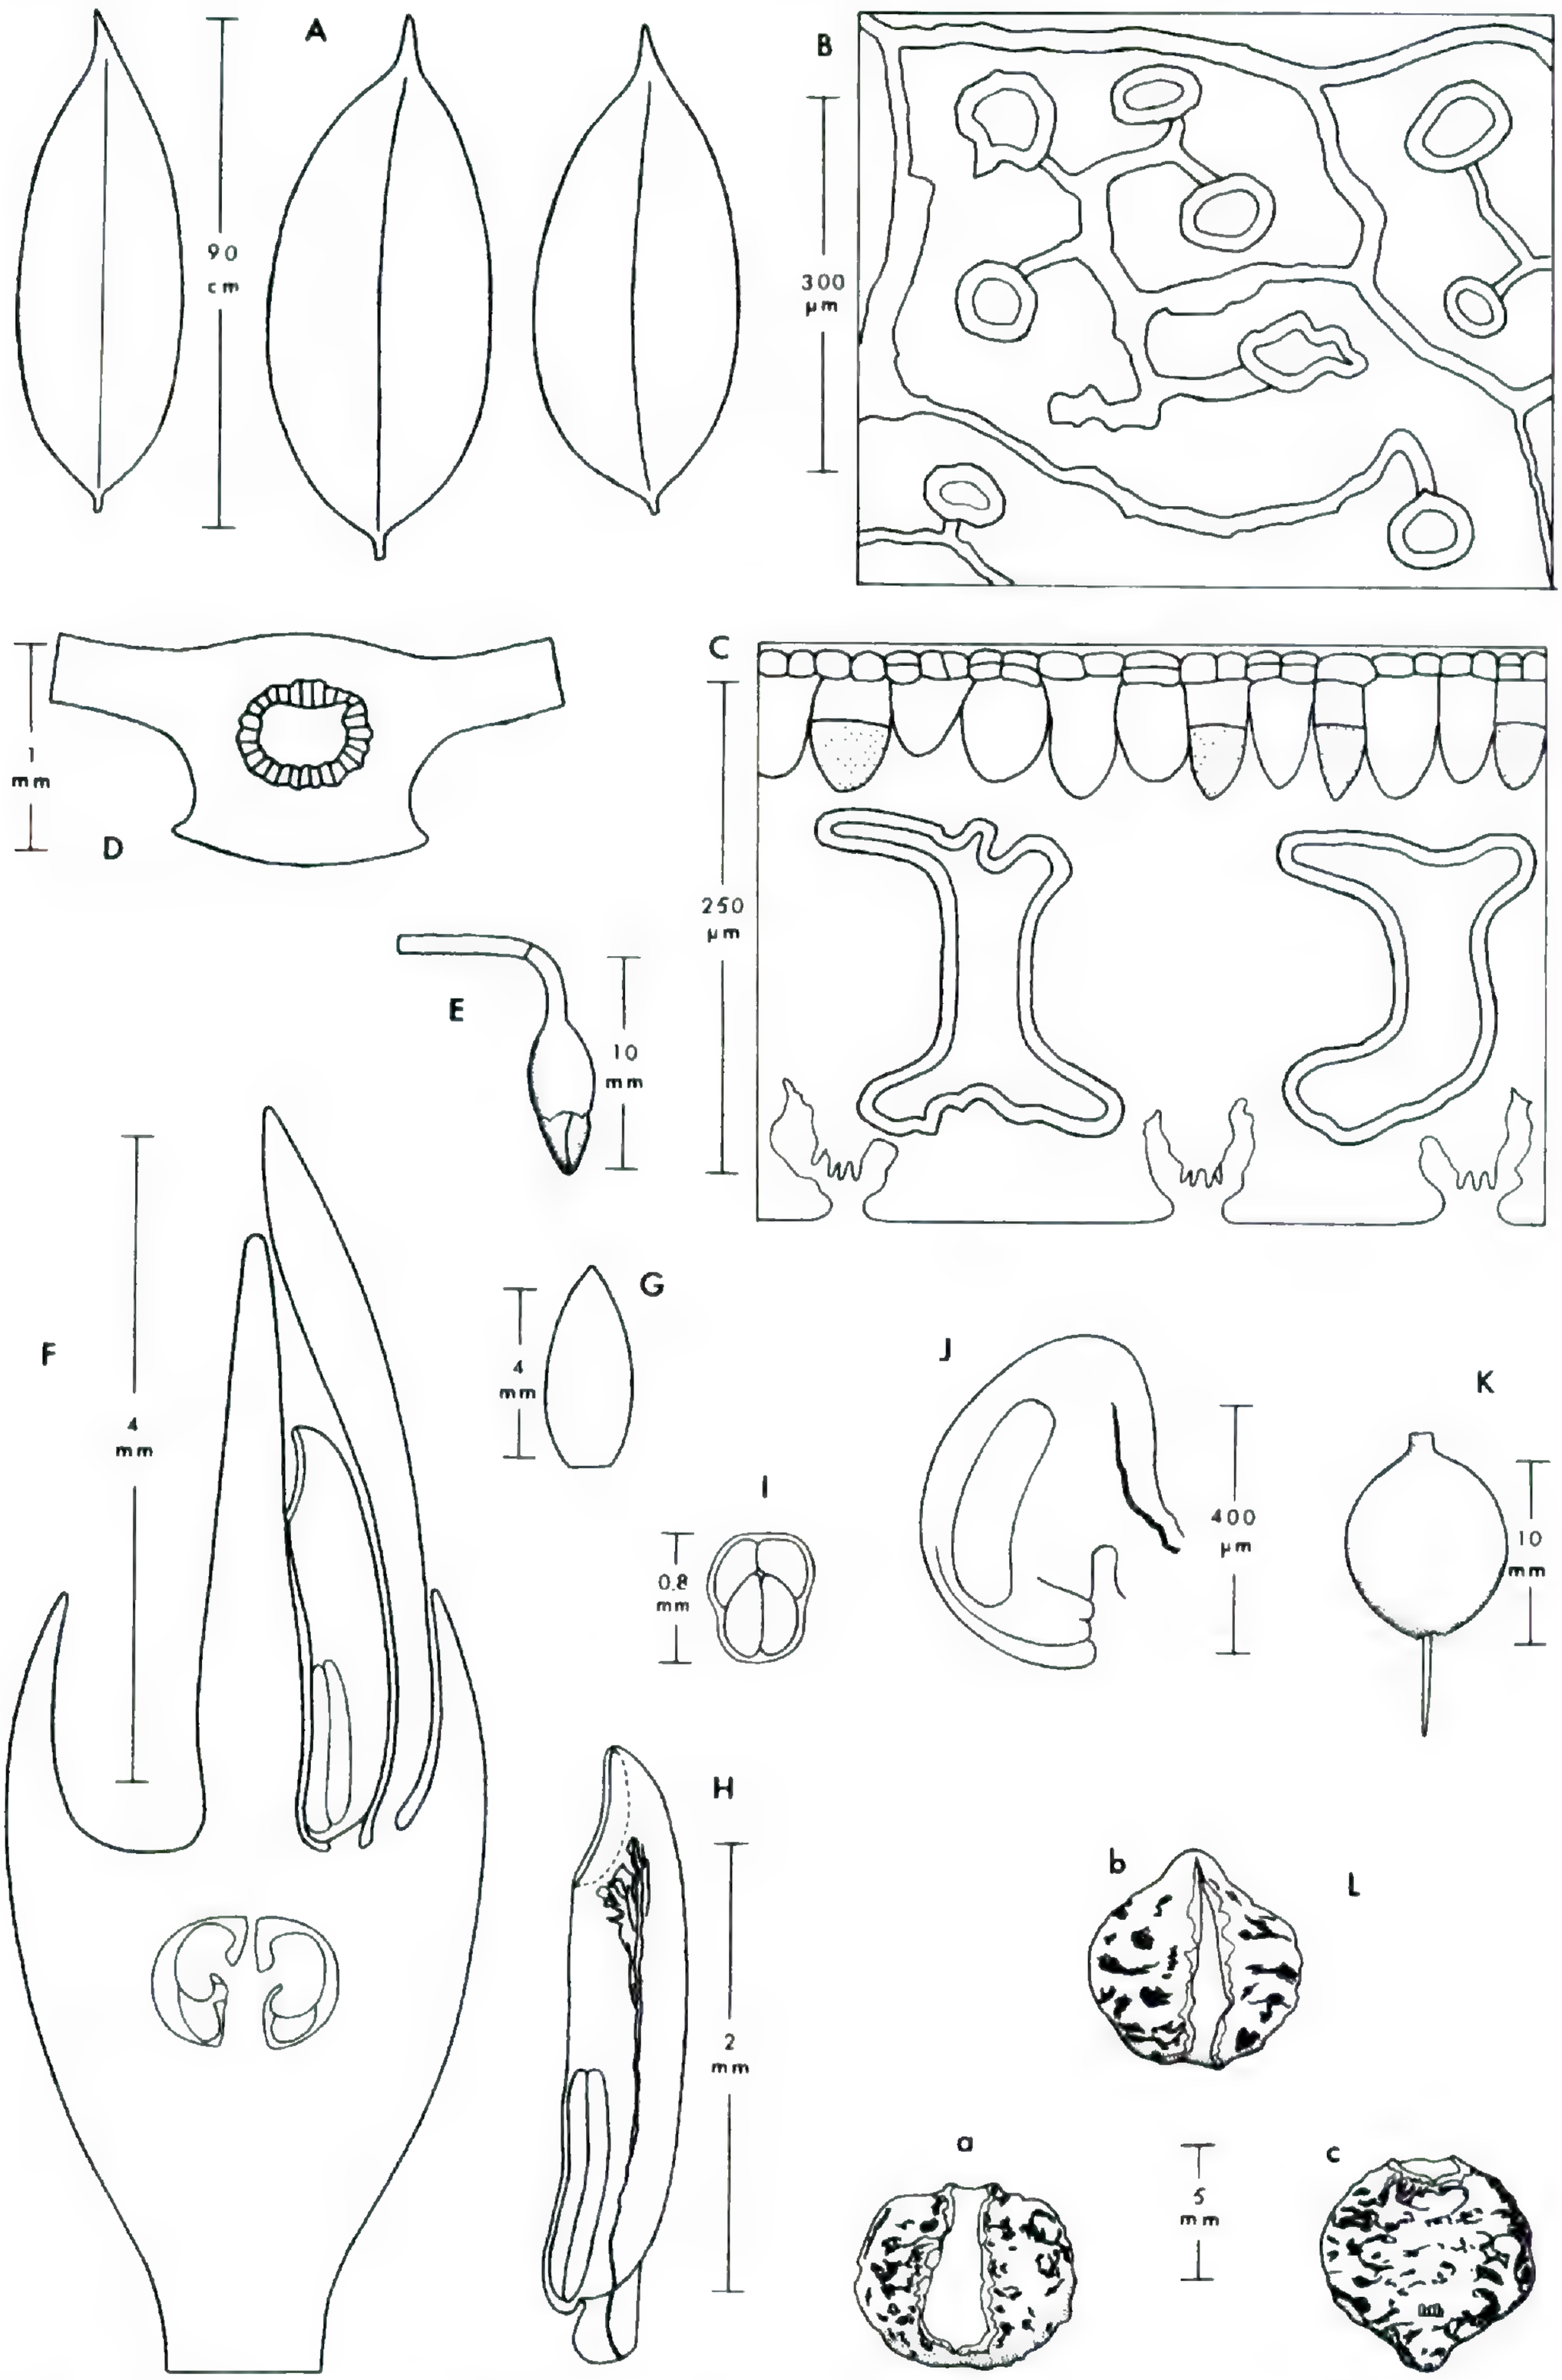

FIGURE 6. *Votomita roraimensis* (*Hopkins et al. 502*).—A. Leaves.—B. Cleared portion of leaf blade showing veins and terminal sclereids.—C. This species is identified more by its combination of features than by any unusual characters. It is allied to the other four species that have four locules or placentas, numerous ovules, and (with one exception) hairs on the midrib. Its laterally fused stamens occur in two members of this group of four, *V. plerocarpa* and *V. monadelpha*. From all of these the new species differs in having much smaller leaves and flowers and only 15–16 ovules. Three of the other four, *V. monadelpha*, *V. orbinaxia*, and *V. plerocarpa*, have 36–48 ovules. The fourth, *V. pubescens*, is closest in ovule number with 20–26, but the new species differs greatly from that species by having small nearly glabrous leaves, a nonindurated ovary wall, laterally fused stamens, four locules, and a persistent style. The remaining three species in the genus, *V. guianensis*, *V. orinocensis*, and *V. monantha*, have one-locular ovaries with 8–10 ovules and glabrous midribs. Because of its small leaves, small flowers, and geographic proximity, a close relation of *V. roraimensis* to *V. orinocensis* and the related Cuban species *V. monantha* seems likely, although the floral structure mostly does not sustain this view. The small leaves, deep hypoderm, and persistent style of the new species in particular suggest *V. monantha*, although the hypoderm of the former differs in having abundant mucilage walls.

Ovules in *Votomita* and *Mouriri* vary from a campylotropous type in which the ovule is bent at a sharp angle from a short, broad placental attachment at the chalazal end to half-anatropous, and fully anatropous forms occur in *Mouriri*. In *V. pubescens* and *V. roraimensis*, the ovules are half-anatropous and are borne on an axile placenta, the only known examples of such a combination in the two genera. In *Mouriri*, half-anatropous ovules occur only on axile-basal, free central, or basal placentas. In *V. pubescens*, the ovules are sessile laterally with extruded inner integuments that appear to serve as internal stigmas (Fig. 7D).

Seeds are known in three species of *Votomita*: *V. monantha*, *V. pubescens*, and *V. roraimensis*. In *V. monantha*, which has free-central placentation, the angular distance on the seed between the micropyle and the broken chalazal strand is about 94°, while in *V. roraimensis* and *V. pubescens*, with axile placentation, the angles are 60° and 50° respectively.

In *V. monantha* the whole abaxial (outer) surface of the seed is smooth, whereas in *V. roraimensis* and *V. pubescens* the smooth part is narrow and is broadest at or near the micropylar end (Figs. 6L, 7F). In none of these seeds is the smooth part polished. Seeds of the latter two species resemble superficially seeds found in *Mouriri* sect. *Brevipedillus*; however, in that section the smooth area is narrowest at the micropylar end and is usually conspicuously widened at the opposite end nearest the broken chalazal strand. I have no explanation for the difference in shape.

The reason for the smooth area is unknown; it may be that this is the part of the ovule first pushed against the ovary wall as enlargement begins.

The Genus Question

Partial generic differences between *Votomita* and *Mouriri* in ovule and seed structure are suggested by the above and may be summarized thusly: (1) half-anatropous ovules on an axile placenta occur only in some species of *Votomita*; (2) the smooth area of the seed is unpolished in *Votomita* but is polished in almost all species of *Mouriri*; (3) in no known species of *Votomita* does the smooth area cover all of the seed except for the hilum, as it does in seeds of the subgenus *Mouriri*; and (4) seeds of *Votomita* most closely resembling those of *Mouriri* are found only in sections *Acutiflos* and *Brevipedillus* of *Mouriri* subg. *Taphroxylon*. Seeds of *V. monantha* somewhat resemble those of sect. *Acutiflos* but lack the polished face and rugose surrounding area of the seeds of that section. Seeds of *V. pubescens* and *V. roraimensis* have narrow smooth areas with surrounding rugose surfaces as in *Mouriri* sect. *Brevipedillus*, but the smooth parts differ in shape as described above.

The above considerations may affect present generic divisions. The seed structure in *V. roraimensis* and *V. pubescens* maintains the difference between *Votomita* and *Mouriri* subg. *Mouriri* but increases the resemblance between *Votomita* and *Mouriri* subg. *Taphroxylon*.

It may be that the New World Memecyleae should be regarded as consisting of three genera or subgenera: *Votomita*, *Mouriri*, and *Taphroxylon*. Absolute differences exist between all three groups, the most between *Votomita* and subg. *Taphroxylon*, the fewest between subgenera *Taphroxylon* and *Mouriri*, thus supporting the present disposition of these groups. Between *Votomita* and subg. *Taphroxylon* the differences are those of midrib xylem form, flower mery, hypanthium development with accompanying features of stamen form, and the presence or absence of free stone cells in the petals. Between *Votomita* and subg. *Mouriri* the differences are the presence or absence of free stone cells in the petals, and seed structure; between subgenera *Taphroxylon* and *Mouriri* the single absolute difference is that of

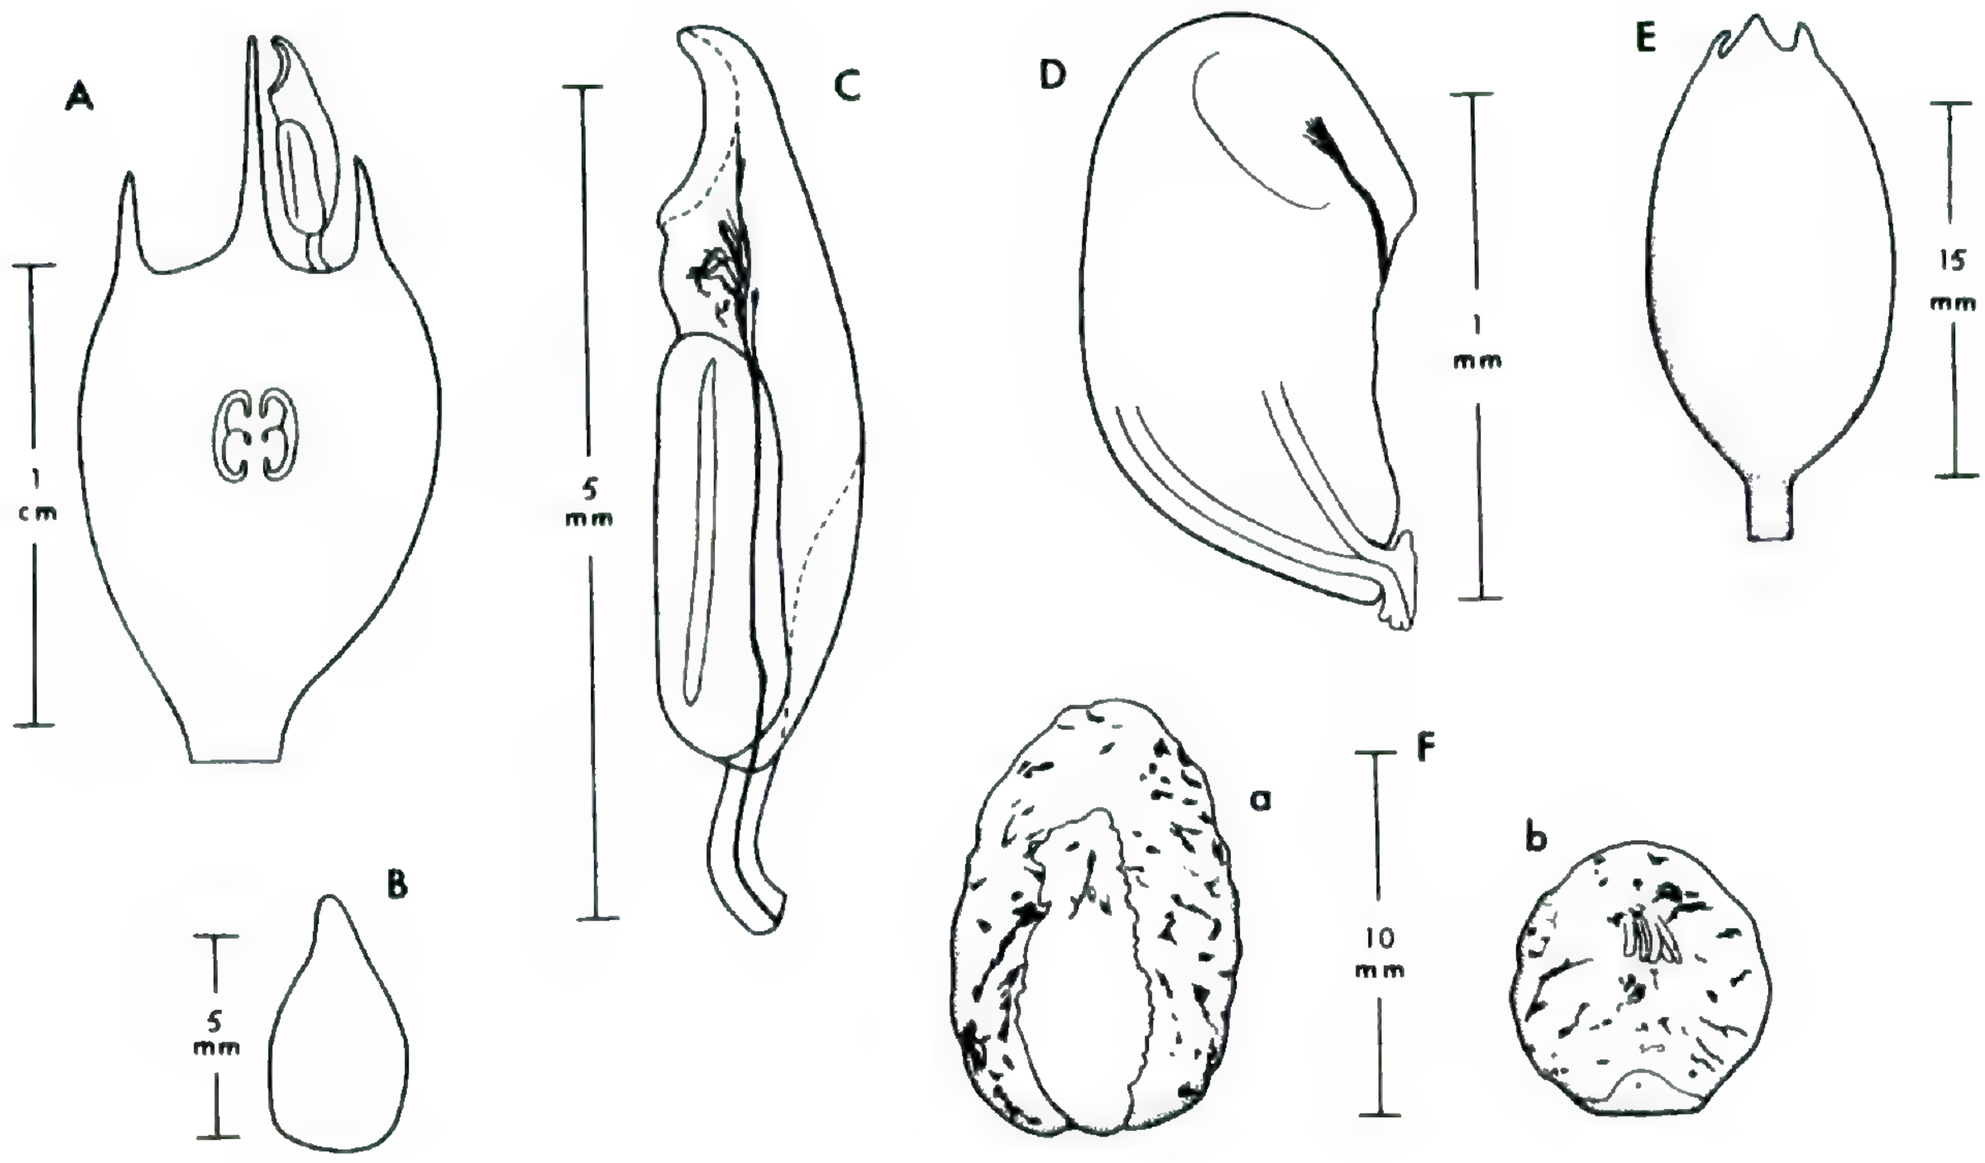

FIGURE 7. *Votomita pubescens*.—A. Longisection of flower (ovules copied from Morley, 1985, *Lao 22*).—B. Petal.—C. Anther, shown cleared (*Bernardi s.n.*, tree 5-145).—D. Ovule (*Lao 22*).—E. Immature fruit.—F. Seed: a, lengthwise view showing smooth face; b, underside. (A, B, E, F, *Bernardi s.n.*, tree 2/168.)

seed structure. On this basis *Votomita* is overall more like subg. *Mouriri* than subg. *Taphroxylon*, even though seed structure in *Votomita* is more like that of the latter.

Because the above differences do not negate the present arrangement of genera, I think any serious effort to reconsider the generic divisions must await more evidence. Seeds of more species of *Votomita* should be examined, and detailed comparative studies of wood anatomy, karyotypes, and phytochemistry may be expected to aid in the evaluation. When the similarities and dissimilarities between the three are well known it can then be decided how many of them should be assigned generic status.

Votomita pubescens Morley. Several more collections of this species have been made from the same area as the type. Among these are specimens with petals, stamens, fruit, and seed—all lacking from the type. An extended and illustrated (Fig. 7) description of the species is therefore presented, omitting the anatomical features, which are not modified.

Tree to 16 m high. Petiole 4–6.5 mm long; leaf blades 10.5–15.5 cm long, 3.6–6.5 cm wide, elliptic or slightly elliptic-ovate, abruptly caudate at the apex with a cauda 11–13 mm long, medium acute at base, glabrous above, pubescent beneath; midrib nearly plane above but with a slight groove down the center, prominent below, the underside rounded at the petiole but abaxially soon 2-angled with 2 very narrow wings for its length, pubescent on the sides; lateral nerves not visible above or below when dry. Peduncles axillary, 1 or 2 per side, each 2–9-flowered, 19–53 mm long to base of farthest pedicel measured along the axes and with 1–3 internodes in that length; bracts unknown, deciduous before anthesis. True pedicels 8–11 mm long; flowers 4-merous, white or yellow; calyx including inferior ovary 10.3–13.3 mm long, 7.8–9 mm thick, glabrous, shrinking only slightly on drying, when dry with a hard, smooth, somewhat polished olive-green to brown outer layer, the ovary widest ½–⅔ of the way above the base; calyx lobes separate, 0.9–2 mm long, 2.4–2.7 mm wide, triangular and slightly apiculate, not separating further at anthesis. Immature petals oblong-ovate, 6.5 mm long, 3.5–3.7 mm wide. Stamens 4–5.5 mm long; filaments 1.2–1.5 mm long; anthers coherent, apparently not truly fused, 3.6–4.5 mm long; thecae 2–2.5 mm long; gland terminal, concave, 0.8–1.2 mm long. Ovary 2-locular, each locule with 2 axile placentas and an irregular very incomplete ridge running down the outer wall representing a missing partition; ovules sessile with an extruded inner integument, 5–7 per placenta, 20–26 in all; style ca. 5 mm long. Fruit maturing red, ellipsoid, ca. 20–24 mm long, 14–18 mm wide. Seed 1, light brown, ovoid-ellipsoid, 12–15 mm high, 8–10 mm wide, 7.5–8 mm thick, with a narrowly ovate, slightly elevated, rather smooth, slightly pebbled, unpolished face (the enlarged outer face of the ovule) extending ¾ of the length of the seed

from the base, the widest end of the face down and turned under opposite the broken chalazal strand, the micropyle in the underturned end; remainder of seed surface rugose.

Vernacular name. Lanza caspi.

STUDY OF THE FLORA OF RUCAMANQUE, CAUTIN PROVINCE, CHILE[1]

Carlos Ramírez,[2] *Enrique Hauenstein,*[3] *José San Martín*[4] *and Domingo Contreras*[3]

ABSTRACT

The flora of forest, scrub, and grass communities was studied in Rucamanque, located near the city of Temuco, Cautín Chile, in the central valley of south central Chile. Forty-six vegetation samples were made, and plants were collected intensively outside the sample areas. A catalog was written for 203 plants species, which were analyzed for systematics, phytogeographics, life forms, the biological spectrum that they compose, the frequency and relative importance of each in the different vegetational communities, and their uses in industry, crafts, and medicine.

Rucamanque, "The House of the Condor" in Mapudungun, the language of the indigenous people of this region (Ramírez-Sánchez, 1985), is a valley located 12 km northwest of the city of Temuco, capital of the IX Region of the Araucanía, Chile (Fig. 1). The primitive forest vegetation of this valley escaped destruction during last century's process of colonization of central southern Chile (Donoso, 1983) because it was protected as an early watershed area for the drinking water for Temuco (Magofke, 1985).

With the increase in population, water for the city had to be drawn from other sources, principally subterranean, so the state lost its interest in Rucamanque and offered it for sale in March of 1986. Because of its value as a forest relict and its scientific interest, several state and private institutions and ecological organizations intervened to preserve it from exploitation. Finally, the University of the Frontera in Temuco became the legal owner, saving the relict forest for science, education, and the general public.

The present catalog of the flora of Rucamanque was made during the time that the land was for sale.

STUDY AREA

Rucamanque is a small river valley oriented southeast–northwest to the south of the Ñielol-Huimpil hills (Magofke et al., 1986). Through it runs Chivilcán Creek, which receives the water of two small unnamed streamlets. Its elevation ranges from 300 to 530 m. The area occupies about 525 ha, including some of the adjacent forests that belong to private owners. The basin and slopes of Rucamanque Valley are covered by native forest, which is evergreen in the lower areas and partially deciduous at higher elevations. In several places the forest has been destroyed and secondary scrub replaces it. In the higher slopes, originally of deciduous forest, permanent grasslands of human origin can be found. Small bogs, which we include in the grassland formation, appear in open areas on the edges of streams at the bottom of the valley.

The climate of the area is humid and temperate with a Mediterranean influence (Di Castri & Hajek, 1976). The average annual rainfall is 1,400 mm and the median annual temperature is 12°C. Rainfall is abundant in winter, and summers often have one to two dry months, as shown in the climatic diagram in Figure 1. Winter and spring frosts are frequent. To this climate corresponds a subtropical semideciduous forest type as natural vegetation (Schmithüsen, 1956).

The Ñielol-Huimpil hills comprise a tectonic unit characteristic of the central valley of Chile and do not connect with either the Coastal Ranges or with the Andes. The red clay soil does show similarity to the Coastal Range soils (Weinberger & Binsack, 1970). When cultivated or grazed, this soil is subject to erosion.

METHODS

The catalog of plant species of Rucamanque was made from 46 vegetation samples taken using the

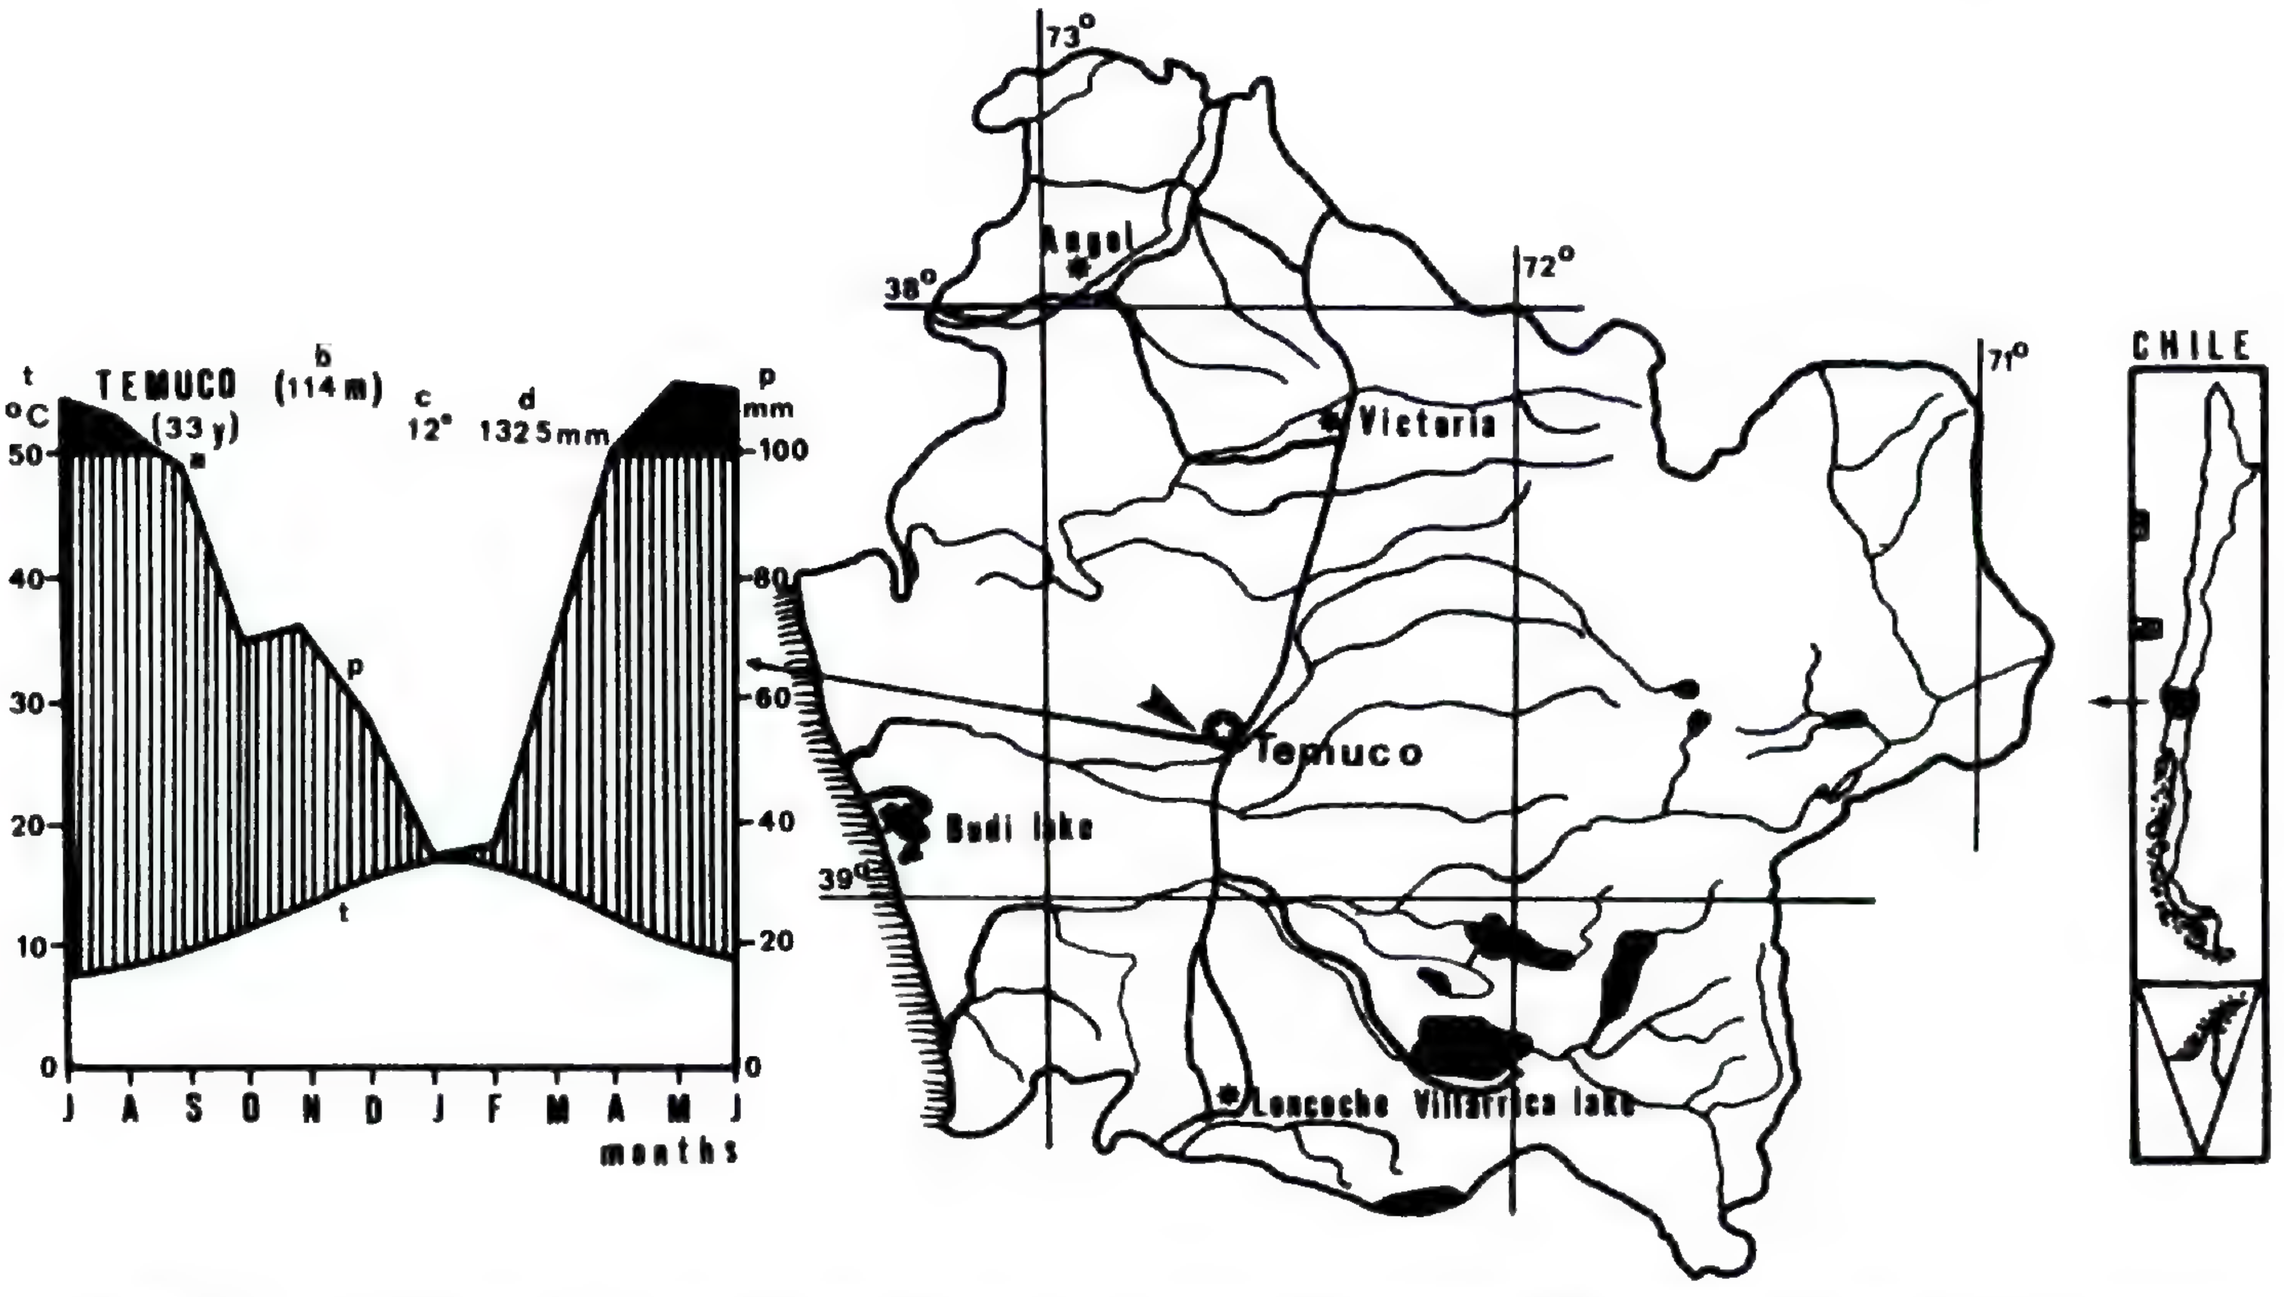

FIGURE 1. Ninth Region of Chile. Climate diagram of Temuco according to Hajek & Di Castri (1975): a = years of observation, b = altitude, c = year average temperature, d = year average precipitation, p = precipitation, t = temperature. Black areas = surplus of precipitation.

Braun-Blanquet (1964) phytosociological method for the study of the local vegetation. Other plants, collected outside the study quadrats, were added to the collection. Eighteen samples were taken in the forest, 20 in scrub vegetation, 6 in pastures, and 2 in bogs. The vegetation contains the following associations: *Lapagerio–Aextoxiconetum punctatii*, *Nothofago–Perseetum linguae*, *Fuchsio–Chusqueetum quilae*, *Rhaphithamno–Aristotelietum chilensis*, *Chusqueetum coleu*, *Aristotelio–Rubetum constrictae*, *Hyperico–Agrostidetum castellanae*, and *Juncetum procerii* (Oberdorfer, 1960; Ramírez, 1982; Hilldebrand, 1983).

The frequency of each species was estimated in each plant association. The relative importance value was calculated adding this frequency and the average cover expressed in relative percentage of each species in the different associations according to the Wikum & Shanholtzer (1978) method. This value was not determined for species collected outside the quadrats.

Nomenclature and phytogeographic origin of the taxa were based on Marticorena & Quezada (1985) and the family nomenclature on Cronquist (1981). The common names are according to Muñoz (1966). Introduced species were classified using the German flora by Rauh & Senghas (1968). The collected species were kept in the herbarium of the Institute of Botany, Austral University of Chile (VALD).

Life forms follow the Raunkiaer system (Ellenberg & Mueller-Dombois, 1966). Vines, epiphytes, and parasites were included under phanerophytes. The interpretation of the biological spectrum was based on Cain (1950).

Information was added on the present and potential uses of the plants.

Results and Discussion

The flora of the study area is made up of 203 species, of which 190 were inventoried in the 46 vegetation samples taken in the forest, scrub, and grassland formations (Appendix I). The other 13 species were collected outside the sample quadrats. The 203 species are distributed among 161 genera, 84 families, and 6 classes (Table 1). The class with the greatest number of taxa was Magnoliopsida (dicotyledons), which include almost 69% of the species present in Rucamanque. Following these are the Liliopsida (monocotyledons) with 42 species (21%), and the Polypodiopsida (Filicinae) with 16 species (8%).

The best-represented family of the Magnoliopsida was the Asteraceae, with 18 genera and 25 species, amounting to 12% of the total. Next came the Fabaceae with 4 genera and 9 species, the Apiaceae with 6 genera and species, the Lamiaceae and Rosaceae with 5 species each, and the Myrtaceae, Proteaceae, and Scrophulariaceae with 4

TABLE 1. Taxonomic distribution of the flora of Rucamanque.

Classes	Families	Genera	Species (%)
Bryopsida	3	3	3 (1.47)
Equisetopsida	1	1	1 (0.49)
Polypodiopsida	7	9	16 (7.88)
Pinopsida	1	1	1 (0.49)
Magnoliopsida	60	115	140 (68.96)
Liliopsida	12	32	42 (20.68)

TABLE 2. Phytogeographic origin of the flora of Rucamanque, distributed by class. Percentages in parentheses.

Classes	Native	Introduced	Total
Bryopsida	3	0	3
Equisetopsida	1	0	1
Polypodiopsida	16	0	16
Pinopsida	1	0	1
Magnoliopsida	96 (68.6)	44 (31.4)	140
Liliopsida	30 (71.4)	12 (28.6)	42
Total	147 (72.41)	56 (27.58)	203

species each. Outstanding among the Liliopsida are the Poaceae, with 16 genera and 18 species, the Cyperaceae with 5, and the Juncaceae with 4 species. Among the ferns, the Hymenophyllaceae presented 6 species, all of which were epiphytes in the forest formation.

ORIGIN

Of the 203 species, 147 (72.41%) are native and 56 (27.58%) are introduced (Table 2). This high percentage of introduced weeds indicates a strong human influence on the vegetation (Sukopp, 1969). The introduced species only belong to the classes Magnoliopsida and Liliopsida, and make up 31.4% and 28.6% of each group, respectively. Of course the greatest percentage of introduced species is found in the shrub grassland formations, of anthropic and therefore secondary, origin (Ramírez, 1982). The evergreen forest of *Aextoxicon punctatum* is the association least invaded by weeds. The majority of the introduced species are originally European and of little grazing value (Montaldo, 1975; Añazco et al., 1981).

LIFE FORMS

The biological spectrum of the study area was constructed from 200 species; the remaining three were mosses. In the epiphytic synusia that were not considered, mosses are very abundant (Riveros & Ramírez, 1978). The most-represented life form was the phanerophytes with 80 species, representing 40% of the total. This life form abounds in forest and scrub formations, occupying different strata in the vegetation. Chamaephytes and cryptophytes were the scarcest, with eight species (4%) each. Hemicryptophytes appeared in about the same numbers as phanerophytes, with 78 species, or 39%. Therophytes were represented by 26 species, or 13%. The latter two herbaceous life forms were abundant in grassy and scrub formations (Table 3).

The biological spectrum here described (Fig. 2) corresponds to a phanerophytic phytoclimate, typical of intermediate latitudes in temperate zones (Cain, 1950). The relative abundance of hemicryptophytes and therophytes is related to the degree of anthropic intervention suffered by the original vegetation. In the original vegetation, these life forms certainly were not as important.

This is confirmed by separating the native elements from the introduced for each life form (Table 4, Fig. 3). Only one of 80 phanerophytes is exotic. The cryptophytes are all native. Among the chamaephytes and hemicryptophytes, the percentage of introduced species is much higher, reaching 37.5% and 38.5%, respectively. Cryptophytes are not very frequent, unlike the hemicryptophytes, which contribute 30 exotic species. These perennial cespitose herbs and rosettes are plants that accompany man and do not characterize any particular phytoclimate (Le Blanc, 1963). Their abundance is due to destruction of forest and to grazing, which impedes their replacement by more aggressive woody species (Pessot & Montaldo, 1974).

The therophytes constitute a special case of plants typical of dry climate or weeds of cultivated areas. They act as pioneers in uncovered soil (Cain, 1950). Only 15% of the therophytes present in the study area are native. This life form was scarce in the original vegetation but invaded anthropogenic grasslands formed on eroded soils, where the vegetational cover never reaches 100%. Thus, therophytes are not typical of Rucamanque.

The phanerophytes, therefore, make up the most

TABLE 3. Biological spectrum of the flora of Rucamanque.

Life Forms	Species	Percentage
Phanerophytes	80	40%
Chamaephytes	8	4%
Hemicryptophytes	78	39%
Cryptophytes	8	4%
Therophytes	26	13%
Total	200	100%

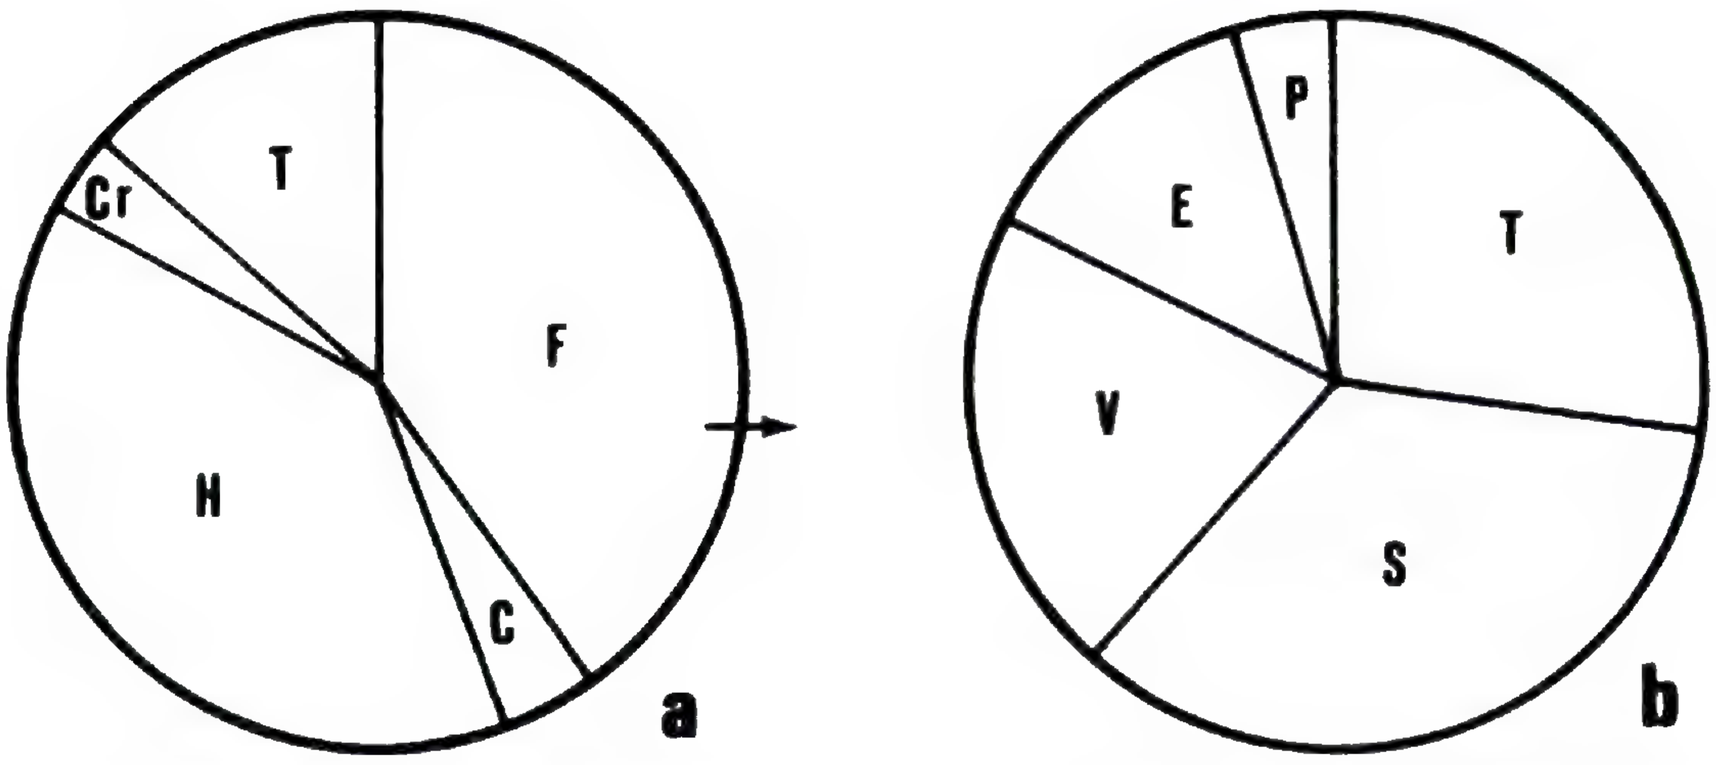

FIGURE 2.—a. Biological spectrum of Rucamanque. F = phanerophytes, C = chaemaephytes, H = hemicryptophytes, Cr = cryptophytes, T = therophytes.—b. Distribution of phanerophytes: T = trees, S = shrubs, V = vines, E = epiphytes, P = parasites.

abundant and representative life form of the research area, including trees, shrubs, epiphytes, and parasites (Table 5). Shrubs were very abundant, with 28 species, 35% of all the phanerophytes. This life form dominates the secondary scrub and tends to invade degraded and abandoned pastures or grassy areas (Ramírez et al., 1984a, 1985). Twenty-two species of trees were present, or 27% of the total.

Sixteen climbing plants flourish in Rucamanque, making up 20% of the total. The most robust of these, *Hydrangea serratifolia*, can have a stem diameter of up to 15 cm. Climbers are typical of forest and proliferate in secondary scrub where more light penetrates. The epiphytes, principally filmy ferns of the Hymenophyllaceae, presented 11 species, or 13.5%. Only three parasitic species were present.

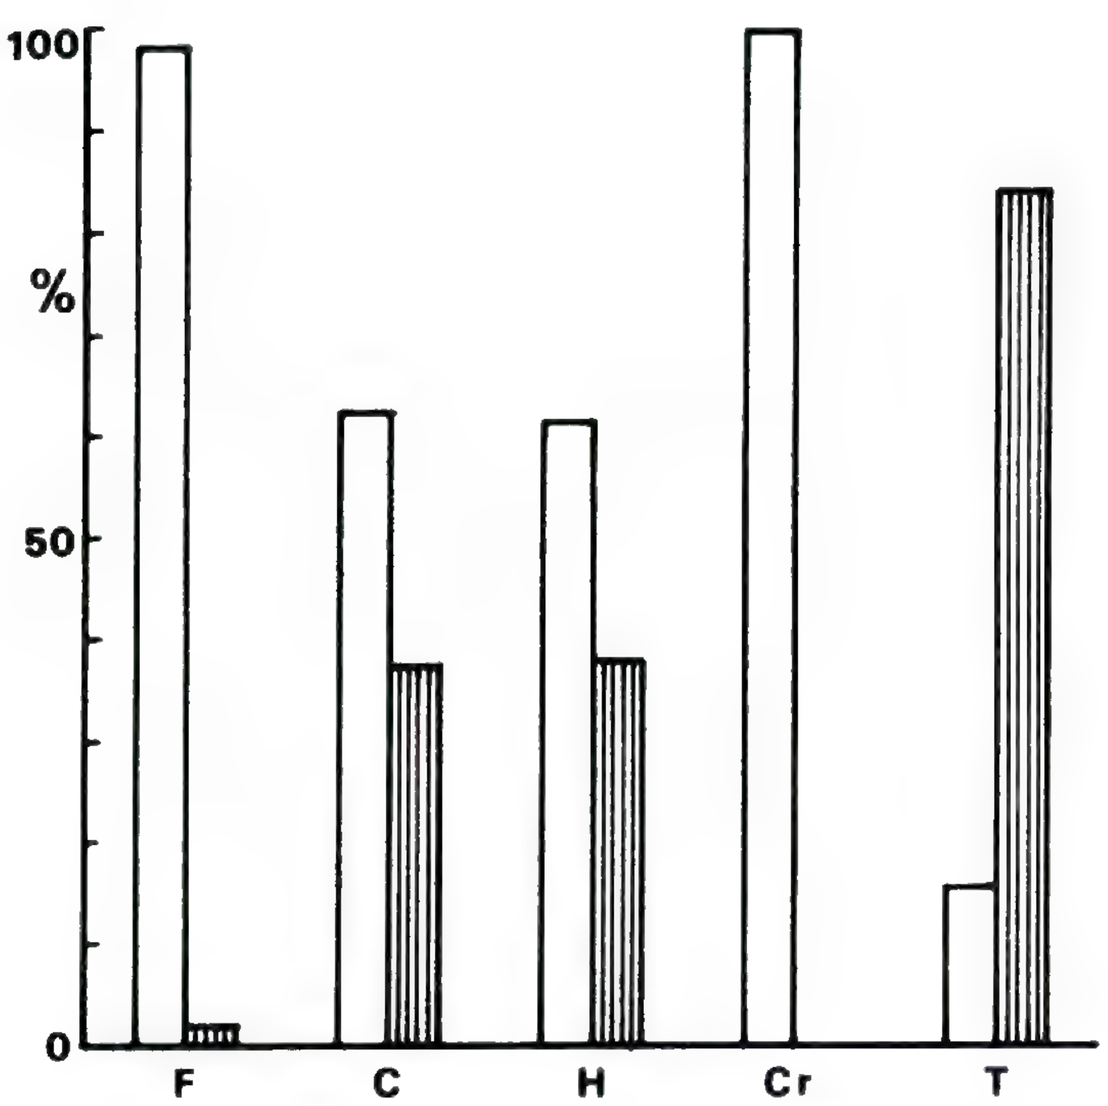

FIGURE 3. Native vs. introduced species in the biological spectrum of Rucamanque. F = phanerophytes, C = chamaephytes, H = hemicryptophytes, Cr = cryptophytes, T = therophytes. White bars = percentage of native species. Hatched bars = percentage of introduced species.

FREQUENCY IN THE PLANT ASSOCIATION

Only two species were present in each of the eight studied plant associations: *Rubus constrictus* and *Prunella vulgaris* (Table 6). These are European weeds, the first a spiny, semiclimbing shrub, and the second, a chamaephytic herb. Both have wide ecological ranges, colonizing any disturbed site in central-southern Chile. Another European species, *Holcus lanatus*, was found in seven of the eight associations studied. In six associations, *Plantago lanceolata*, another European herb, was found along with *Aristotelia chilensis* and *Eucryphia cordifolia*, two native woody species.

Native species with a frequency of five, that is, which occur in five associations, are: *Aextoxicon punctatum*, *Luma apiculata*, *Baccharis racemosa*, *Lapageria rosea*, *Cissus striata*, *Boquila trifoliolata*, and *Blechnum hastatum*. The first two are arboreal species of forests and scrubland; the third is a small shrub fairly frequent in the south of Chile. The remaining three are vines that

TABLE 4. Phytogeographic origin of the plant species of Rucamanque distributed by life form. Percentages in parentheses.

Life Forms	Native	Introduced	Total
Phanerophytes	79 (98.75)	1 (1.25)	80
Chamaephytes	5 (62.50)	3 (37.50)	8
Hemicryptophytes	48 (61.53)	30 (38.47)	78
Cryptophytes	8 (100)	0 (0)	8
Therophytes	4 (15.38)	22 (84.62)	26

TABLE 5. Habits of phanerophytes present in the flora of Rucamanque.

Habits of Phanerophytes	Numbers of Species	Percentage
Trees	22	27.50
Shrubs	28	35.00
Vines	16	20.00
Epiphytes	11	13.75
Parasites	3	3.75
Total	80	100.00

form large populations in secondary brush, and the last is a fern tolerant of a wide range of luminosity, as Godoy et al. (1981) demonstrated. The exotic hemicryptophyte herbs having the same frequency (5) are *Agrostis castellana* and *Rumex acetosella*. The former dominates the grassy vegetation in the study area (Oberdorfer, 1960) and the latter thrives on worn-out soils.

IMPORTANCE VALUES

Chusquea quila, a climbing bamboo, was found to be the most important species in the vegetation of Rucamanque (Table 6). It grows in areas of moist soil (Ramírez et al., 1984b) and prefers light in forest clearings. It forms extensive and impenetrable secondary scrub, locally called "quilantales." Following it with slightly less importance is the blackberry (*Rubus constrictus*), which colonizes all of the vegetational communities in Rucamanque. This blackberry forms scrubby areas called "murrales" when it invades degraded meadows and hedges (Hildebrand, 1983). It is an aggressive, woody plant whose control poses a serious problem in the study region (Ramírez, 1973). The importance of these two shrubs, which belong to disclimax communities, indicates the degree of anthropic intervention found in the vegetation of Rucamanque. They invade areas when the forest has been cut, and in this case make difficult the regeneration of the original forest community (Ramírez et al., 1985).

Third in order of importance is "olivillo" (*Aextoxicon punctatum*), a tall tree that forms evergreen forests in the lowest and deepest parts of Rucamanque Valley. *Aristotelia chilensis* and *Nothofagus obliqua* show similar importance values. The former dominates in shrub communities and the latter in partially deciduous forests of the *Nothofago–Perseetum*. The next-lowest values were found for *Agrostis castellana*, *Chusquea coleu*, and *Juncus procerus*, these dominant in grassy areas, scrub, and bogs, respectively.

TABLE 6. Frequencies in the plant associations, and importance values of the main species of Rucamanque.

Species	Frequencies	Importance Values
Chusquea quila	4	11.69
Rubus constrictus	8	9.33
Aextoxicon punctatum	5	7.92
Aristotelia chilensis	6	6.96
Nothofagus obliqua	4	6.66
Agrostis castellana	5	5.61
Chusquea coleu	2	5.03
Juncus procerus	1	2.93
Blechnum chilense	4	2.81
Eucryphia cordifolia	6	2.46
Prunella vulgaris	8	2.39
Holcus lanatus	7	2.30
Persea lingue	4	2.25
Trifolium repens	4	2.17
Senecio yegua	4	2.00
Plantago lanceolata	6	1.95
Leontodon taraxacoides	2	1.95
Peumus boldus	3	1.91
Cynosurus echinatus	4	1.90
Baccharis racemosa	5	1.88
Conium maculatum	2	1.88
Lapageria rosea	5	1.79
Vulpia bromoides	3	1.77
Baccharis concava	3	1.74
Cissus striata	5	1.64
Leucanthemum vulgare	3	1.62
Blechnum hastatum	5	1.49
Luma apiculata	5	1.49
Boquila trifoliolata	5	1.49
Rumex acetosella	5	1.49

APPLICATIONS

The flora of Rucamanque offers many uses, some of which are employed by the Araucarian Indians (Mapuche) who populate Cautin Province. *Chusquea coleu* and *C. quila* are used in crafts and for the construction of furniture and household articles. To fasten pieces of these bamboos, "voquis" (*Boquila trifoliolata* and *Campsidium valdivianum*) serve as ties. *Juncus procerus* is used to make mats. From *Luma apiculata*, tool handles are cut, and the wood of *Embothrium coccineum* is carved.

Applications as construction materials are important for tree species, including *Aextoxicon punctatum*, *Laurelia sempervirens*, *Persea lingue*, *Nothofagus obliqua*, *N. dombeyi*, and *Weinmannia trichosperma*. Tannins for the leather tanning industry are obtained from the barks of *Persea lingue* and *Weinmannia trichosperma*. Many individuals of the latter species can presently be

found with the bark cut off, resulting from excessive exploitation. *Eucryphia cordifolia* is valued for domestic firewood, and for this reason the tree is being cut so extensively that it risks local extirpation. Edible fruits grow on *Lapageria rosea*, Chile's national flower. "Maqui cider" is made from the berries of *Aristotelia chilensis*. Edible fruits also grow on *Gevuina avellana, Ribes trilobum, Fragaria chiloensis, Ugni molinae, Fuchsia magellanica*, and *Peumus boldus*. The fruits of *Rubus constrictus* are used to make jams.

The bark of *Dasyphyllum diacanthoides* allegedly regulates blood sugar; *Boquila trifoliolata* is applied for eye infections; *Peumus boldus* is used for stomachaches and liver illnesses; an infusion of *Tristerix tetrandrus* is thought to reduce cholesterol in the blood. *Solanum gayanum* is a reputed febrifuge; *Buddleja globosa* allegedly helps heal ulcers; and *Equisetum bogotense* is used as a diuretic. The following introduced plants have applications in popular medicine: *Urtica urens* as an antirheumatic, *Hypericum perforatum* as a vulnerary, and *Mentha rotundifolia* and *M. pulegium* for the stomach.

The rhizomes of *Dioscorea brachybotrya* are edible and high in starch. *Maytenus boaria* and *Chusquea quila* provide excellent winter forage.

NOVELTIES IN THE ORCHID FLORA OF SOUTHERN VENEZUELA[1]

Gustavo A. Romero[2,3]
and Germán Carnevali[2,4]

ABSTRACT

Six new orchids from the Venezuelan Guayana are described and illustrated, including three species, *Coryanthes cataniapoënsis*, *Catasetum gomezii*, and *Catasetum parguazense*, one natural hybrid, *Catasetum* ×*dunstervillei*, and two new natural hybrids previously described as species, *Catasetum* ×*roseo-album* (Hook.) Lindley and *Catasetum* ×*wendlingeri* Foldats. These three hybrids involve four sympatric *Catasetum* species with overlapping flowering seasons that share *Eulaema cingulata* (Fabricius) as their main pollinator.

This paper and others in preparation precede the publication of a comprehensive treatment of the Orchidaceae of southern Venezuela for J. A. Steyermark's *Flora of the Venezuelan Guayana* (Carnevali et al., in prep.). The taxa described here belong to two of the most complex genera in the Orchidaceae, *Coryanthes* Hook. and *Catasetum* Rich. Species in these two genera are extremely variable, and in the Venezuelan Guayana many closely related species are sympatric or syntopic, share pollinators, and have overlapping flowering seasons; natural hybrids are common.

Half of the taxa proposed here are natural hybrids. The parentage of these nothospecies was inferred from pollination data, phenological data, and morphological characters. This approach has its limitations, but one can postulate safely parent species if a large number of specimens of the suspected hybrid are examined, because, as Hurst (1902) indicated, "In orchid hybrids of the first generation single specific characters are inherited in all degrees of blending, forming, on the whole, a perfect series between the respective characters of the two parents." In *Catasetum* ×*wendlingeri* Foldats, the parentage was confirmed by artificial hybridization experiments (A. Pardo, pers. comm., 1988).

Coryanthes cataniapoënsis G. Romero et Carnevali, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Departamento Atures, Río Gavilán, alrededores de Cucurital, 9 May 1987, *G. A. Romero 1307* (holotype, VEN; isotype, K). Figure 1A–C.

Planta *C. macranthae* (Hook.) Hook. affinis sed hypochilo antice producto campanulato et mesochilo subaequilongo differt.

Plant epiphytic in ant gardens. Rhizomes short; pseudobulbs ovoid to narrowly ovoid, grooved, bifoliate at the apex, to 11 cm long, surrounded at the base by scarious sheaths. Leaves oblong-elliptic, acuminate, to 34 cm long, including the short, sulcate petiole; lamina to 9 cm wide and 31 cm long, plicate, with 3 conspicuous nerves beneath. Inflorescence from the base of the pseudobulbs, pendulous, elongate, 1- or 2-flowered at the apex; peduncle slender, to 18 cm long, with short remote tubular-infundibuliform sheaths. Ovary pedicellate, elongate, slender, ca. 15 cm long, almost 4 times as long as the concave, scarious subtending bract. Flowers white, densely spotted and blotched with dark red-maroon. Sepals and petals membranaceous; dorsal sepal ovate, obtuse, ca. 4.3 cm long and 5 cm wide; lateral sepals obliquely oblong-ovate, retrorse, ca. 9 cm long and 6 cm wide, margins involute; petals narrowly oblong-lanceolate, falcate, obtuse, ca. 5 cm long and 1.3 cm wide near the base, margins shallowly undulate.

[1] We are grateful to J. A. Steyermark and B. J. Manara for the line drawings and to P. Beer-Romero, C. Gomez, E. Melgueiro, and J. Moreno for field assistance. We thank R. L. Dressler for having kindly identified a reference collection of euglossine bees; the curators of AMES, BR, K, TFAV, VEN, and W for providing reference material; and A. Pardo for providing data and material on artificial hybrids. This work was financed in part by funds from Indiana University, Sigma Xi, and The American Society of Plant Taxonomists to G. A. Romero. Venezuela's "Fondo Nacional de Investigaciones Agropecuarias" provided logistic support.

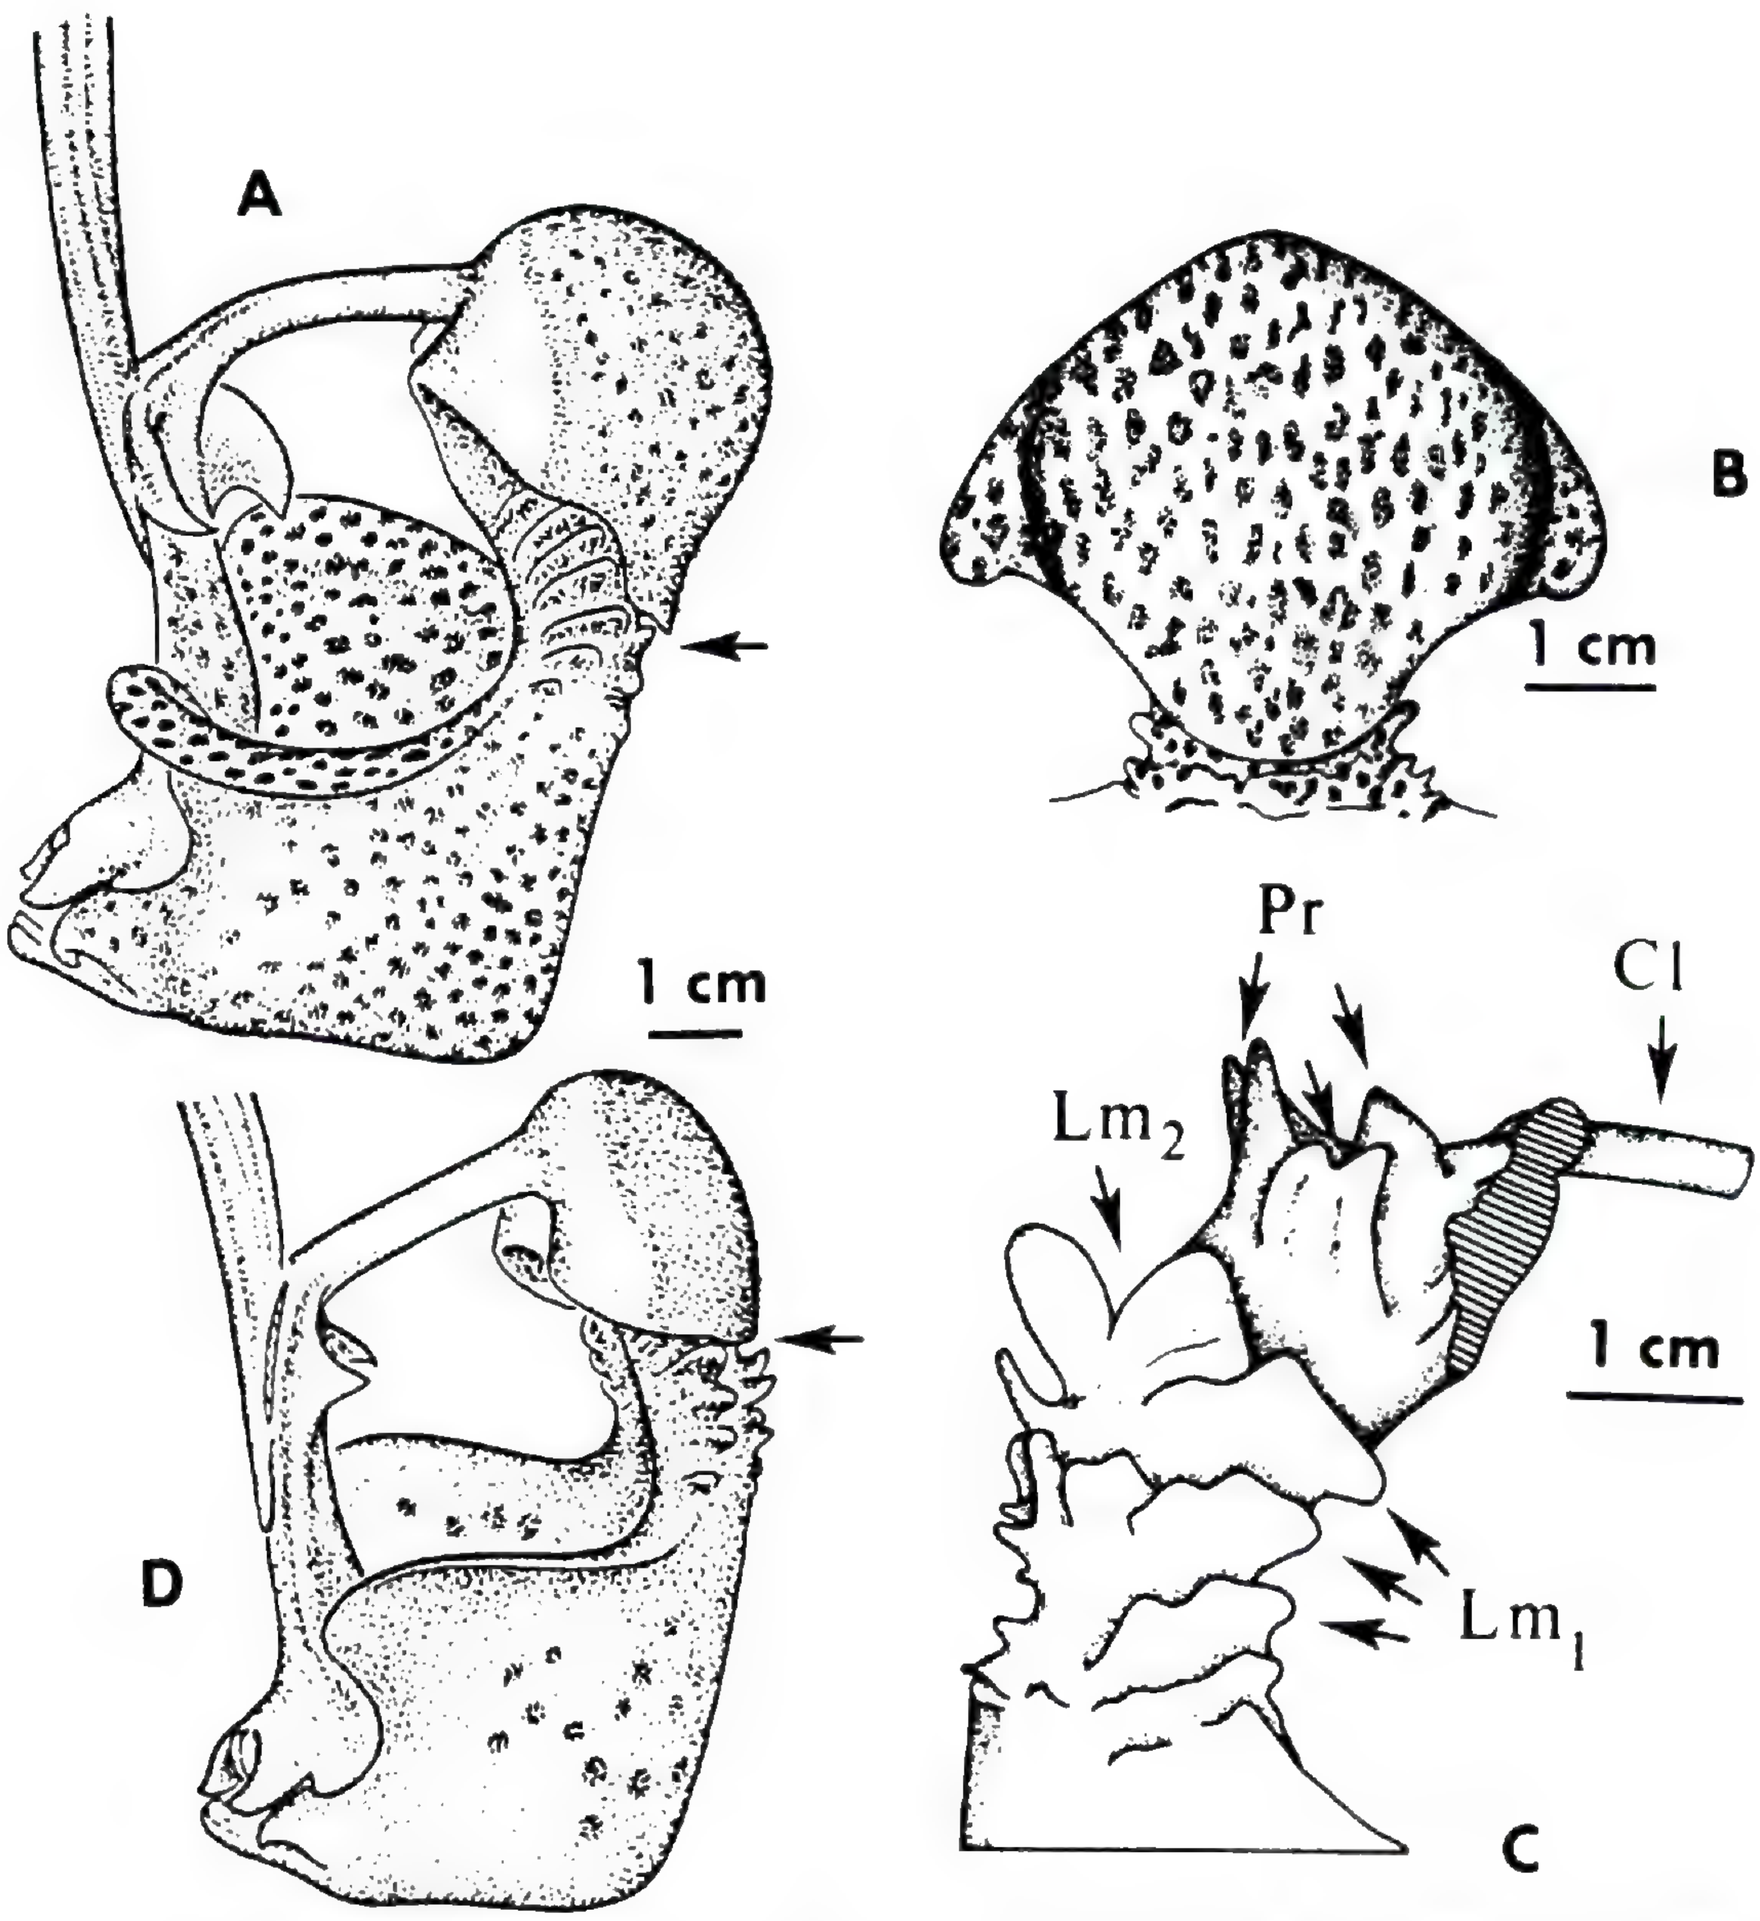

FIGURE 1.—A–C. *Coryanthes cataniapoënsis*. A. Side view of labellum. B. Front view of hypochile. C. Side view of mesochile, after removing hypochile, showing the labellum claw (Cl), the transverse ridges (Lm_1 and Lm_2), and the projections (Pr) near the base (Lm_2 and Pr not visible unless the hypochile is removed).—D. *Coryanthes macrantha* (Hook.) Hook. shown for comparison. A, B from *G. A. Romero 1307*; C from *C. Gomez s.n.*; D from *G. Bergold s.n.* (VEN).

Lip fleshy, divided into 3 parts, the clawed, semispherical hypochile 4.5–5 cm wide; the semitubular mesochile ca. 4–4.5 cm long, with 5–6 transverse ridges, bilobed to multilobed, decreasing in size from the base, with 3 toothlike projections near the base (these seen only after removing the hypochile), 8–13 mm high; the deeply saccate epichile bucketlike, with a 3-lobed apex, the lateral lobes uncinate at the apex, the middle lobe lingulate, shallowly obcordate. Column gradually dilated toward the apex, recurved near the apex, bialate, ca. 2.5 cm long, with a pair of shallowly falcate, fluid-producing glands at the base. Pollinia 2, waxy, yellow.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Departamento Atures, Río Gavilán, alrededores de Cucurital, June 1985, *G. A. Romero 1273* (AMES); Río Cataniapo, entre la boca del Río Gavilán y los Raudales de Rabipelado, Jan. 1985, *C. Gomez s.n.* (TFAV).

Etymology. Named for the Río Cataniapo, where the species was first found.

This species differs from *Coryanthes macrantha* (Hook.) Hook. in the globose hypochile with the anterior margin that almost reaches the epichile, and in the toothlike projections near the base of the mesochile. It flowers from January to June and is pollinated around Puerto Ayacucho, T. F. Amazonas, Venezuela, by *Eulaema cingulata* (Fabricius) and, less frequently, by *E. meriana* (Olivier) (G. A. Romero, unpubl. data).

Catasetum gomezii G. Romero et Carnevali, sp. nov. TYPE: Venezuela. Territorio Federal Amazonas: Departamento Atures, Río Cataniapo, cerca de la desembocadura del Río Gavilán, 30 June 1987, *G. A. Romero & C. Gomez 1333* (holotype, VEN; isotypes, K, TFAV). Figure 2A–B.

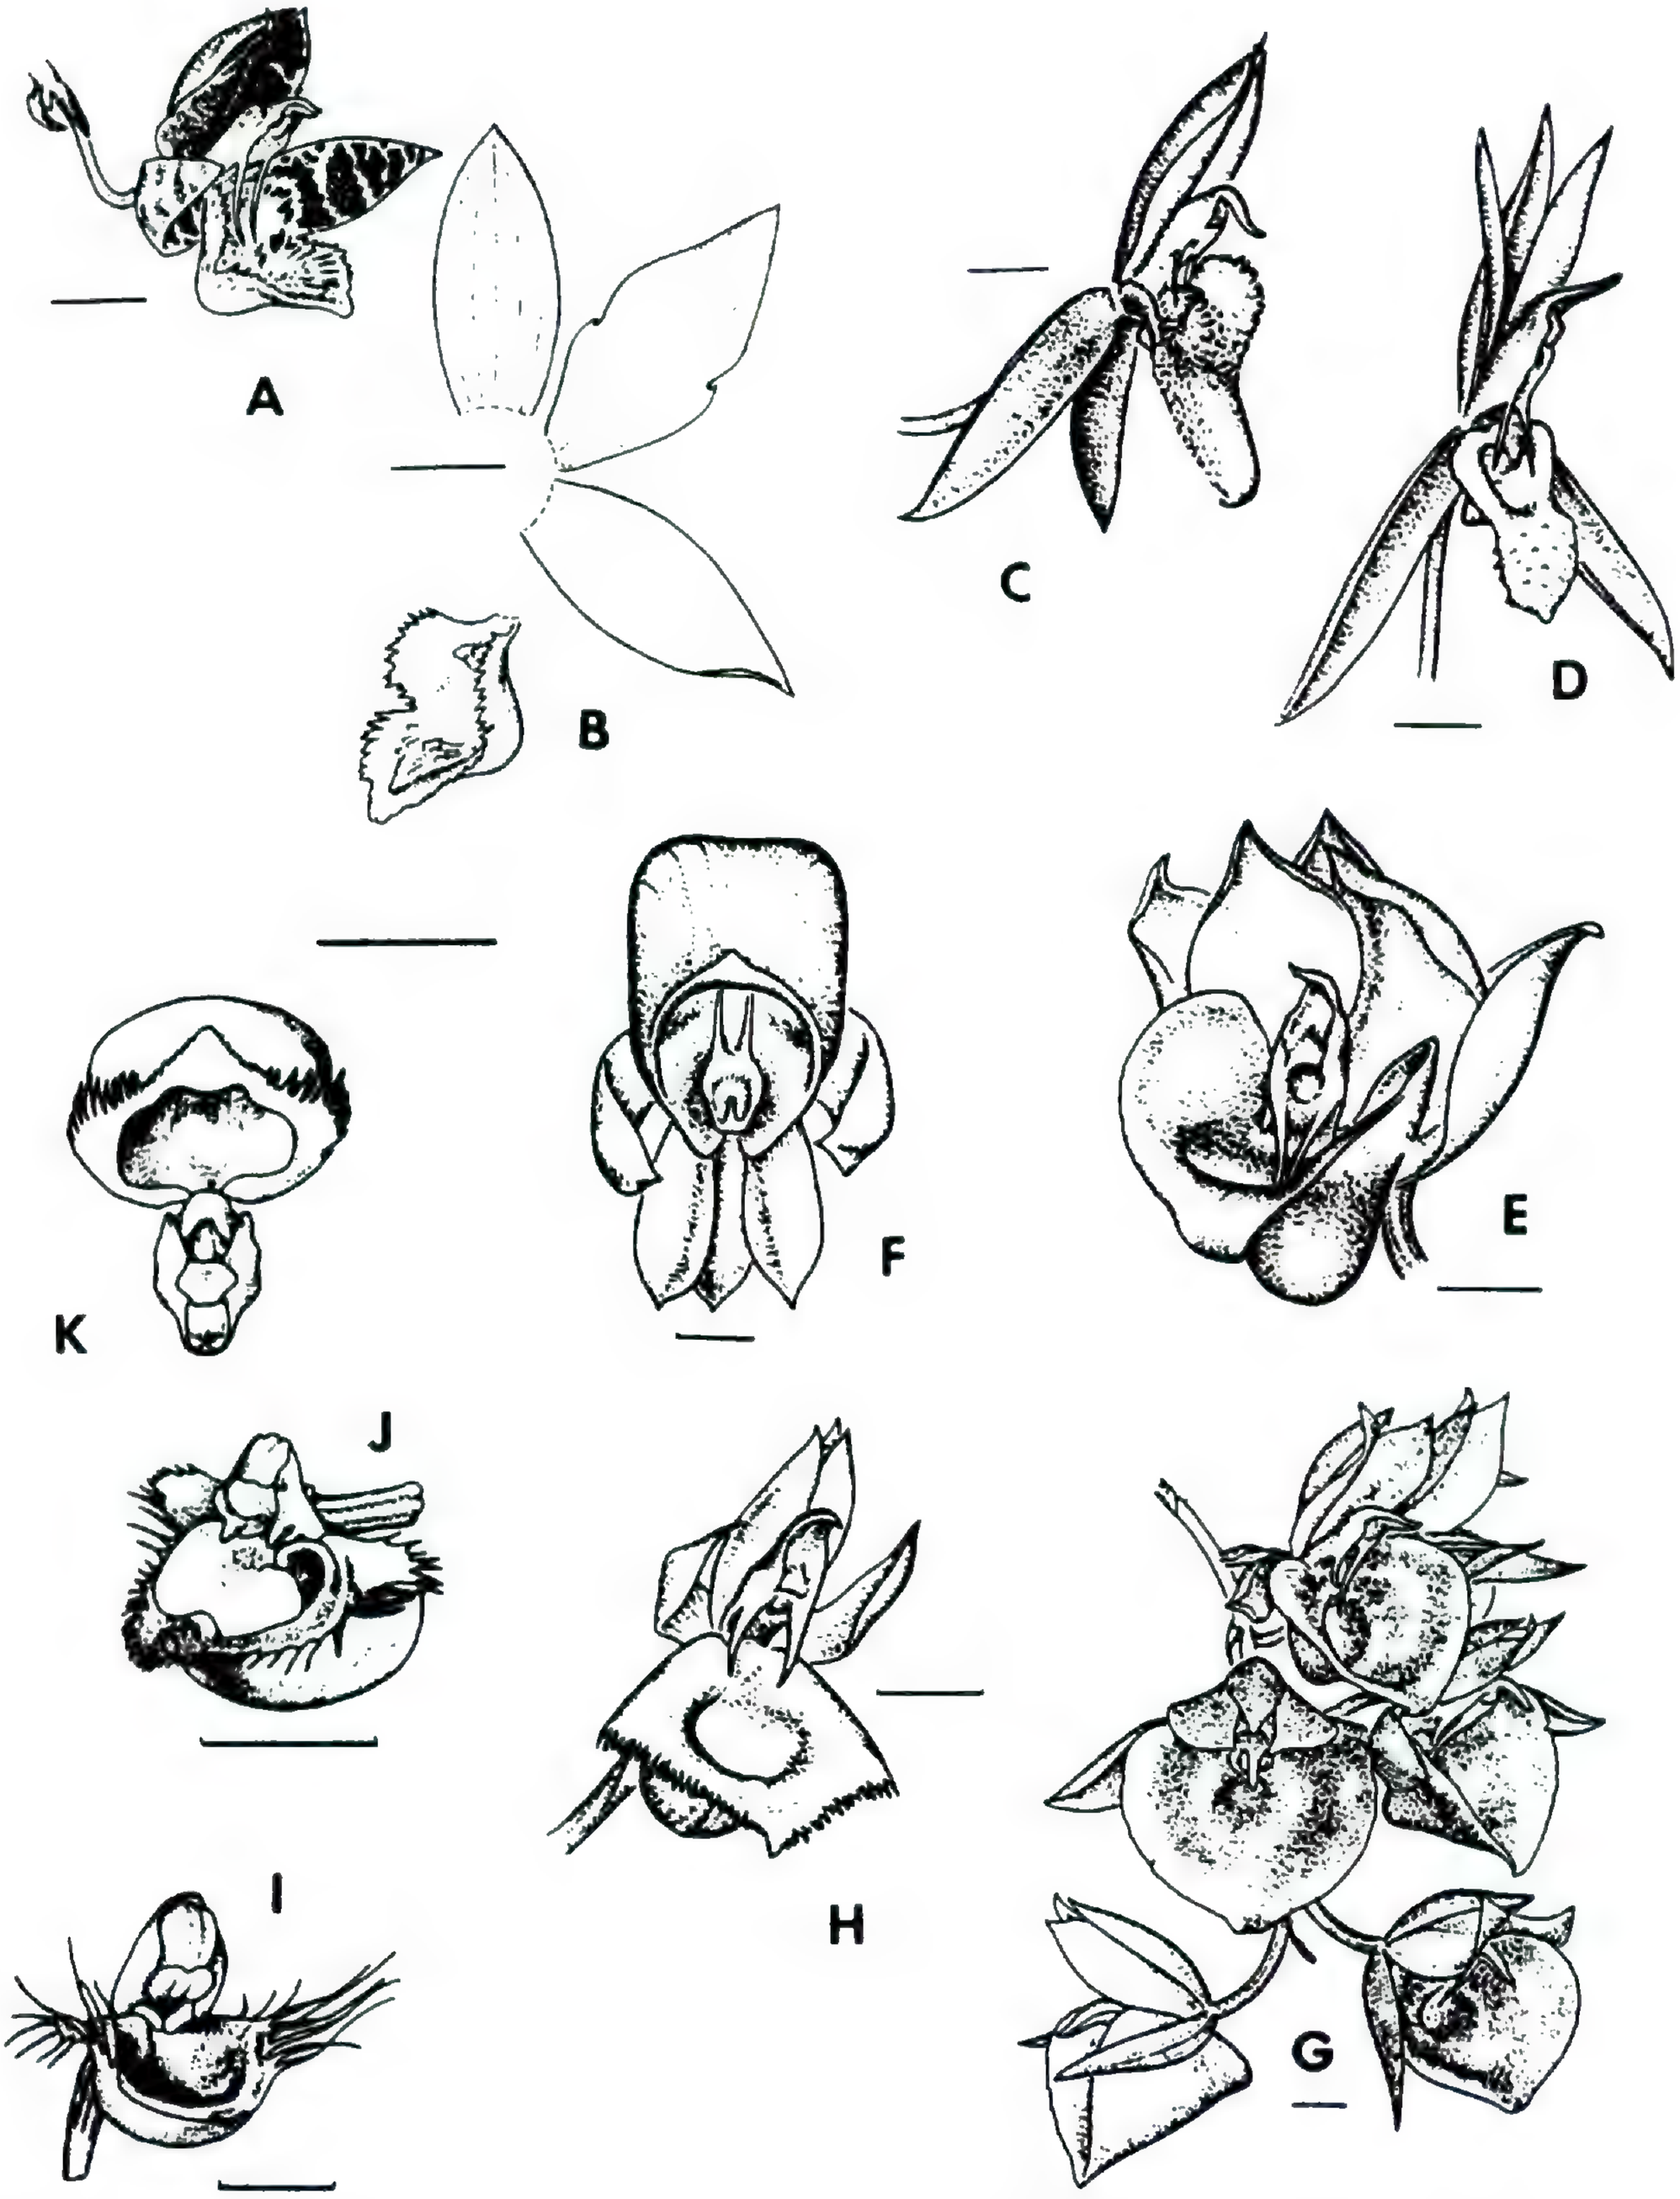

FIGURE 2.—A, B. *Catasetum gomezii*. A. Staminate flower. B. Scale bars = 1 cm. A, B from *G. A. Romero & C. Gomez 1333*; C from *E. Rutkis 185*; D redrawn from Foldats, 1970: 59; E from *G. A. Romero & L. Rojas 1201*; H from *G. A. Romero & A. Cortez 914*; I, K redrawn from the plates accompanying the original descriptions (Hooker, 1840, and Lindley, 1834, respectively); and J from Saunders, 1882.

Planta inter *C. barbatum* Lindley et *C. ochraceum* Lindley quasi intermedia, sed ab ambas labello saccatissimo marginibus dentatis differt.

Plant epiphytic, indistinguishable vegetatively from other members of the genus. Staminate inflorescence lightly arcuate to pendent, racemose, to 9-flowered, originating from the base of the fully developed pseudobulb, to 18 cm long. Staminate flowers resupinate. Tepals light green, densely spotted with maroon on their inner surface, less so on their outer surface; dorsal sepal slightly concave, oblanceolate, acute, margins entire, 11–12 mm

wide, 25–26 mm long; lateral sepals slightly concave, oblong-lanceolate, acute or shortly apiculate, slightly oblique, margins entire, 12–13 mm wide, 27–28 mm long; petals narrowly ovate, acute, margins entire or finely serrate with 1 indentation and a flush falcate tooth on each side at the widest point, 10–11 mm wide, 24–25 mm long. Labellum fleshy, rigid, yellowish green, spotted with maroon in the margins, deeply concave, deltate in general outline, with 2 lateral indentations midway between the base and the apex, thus slightly trilobulate, 12 mm deep, 22 mm long, 22 mm wide between the spread basal lobes, margins crenate to dentate in the middle lobe, dentate to fimbriate in the lateral lobes, the base with a transverse, tricuspid callus, the apex with a V-shaped, verrucose callus. Column yellowish green, with maroon dots in the inner surface near the base, densely spotted with maroon on the outer surface, semiterete, stout, straight, apically thickened, conspicuously rostrate, the clinandrium apiculate and slightly incurved at the apex; antennae bilaterally symmetrical, slightly convergent, 8 mm long. Anther white, the margins spotted with maroon. Pollinia 2, cleft, waxy, compressed, more than twice as long as wide, attached to a light yellowish green stipe with a white, adhesive viscidium. Pistillate inflorescence unknown.

Etymology. Named in honor of Carlos Gomez, the discoverer of this species.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: Departamento Atures, Río Cataniapo, entre el Milagro y San Pablo, 1 Sept. 1987, *G. A. Romero, C. Gomez & P. L. Beer-Romero 1365* (AMES, TFAV).

This showy species resembles *Catasetum ochraceum* Lindley (Lindley, 1844) but differs in the epiphytic habit, pendulous inflorescence and labellum with dentate to fimbriate margins. It is also similar to *C. cornutum* Lindley (Lindley, 1840) and the recently described *C. semicirculatum* Miranda (Miranda, 1986), but the new species is distinguished by the deeply concave labellum with a frontal, V-shaped callus. It flowers from May to September.

Catasetum parguazense G. Romero et Carnevali sp. nov. TYPE: Venezuela. Bolívar: Distrito Cedeño, Río Parguaza, 12 May 1967, *E. Rutkis 1985* (holotype, VEN). Figure 2C.

Planta *Cataseto calloso* Lindley et eius affinitatis proxima, sed labello basi subcordato et callo basali truncato differt.

Plant epiphytic, indistinguishable vegetatively from other members of the genus. Staminate inflorescence lightly arcuate to pendulous, racemose, to 8-flowered, originating from the developing leaf growth, to 15 cm long. Staminate flowers resupinate. Tepals tinged green with maroon, or maroon entirely; dorsal sepal narrowly elliptic or narrowly obovate, acute or acuminate, somewhat concave, margins entire or slightly ciliolate, 29–31 mm long, 7–10 mm wide; lateral sepals similar to dorsal sepal but slightly oblique, 9–10 mm wide; petals narrowly elliptic to narrowly obovate-elliptic, acute or shortly acuminate, margins entire or finely denticulate to ciliolate, 26–31 mm long, 7–9 mm wide. Labellum green with maroon dots or maroon entirely. Labellum fleshy, in general outline narrowly ovate, obtuse, rounded to truncate, basal margins extended, making the labellum subtrilobate, 2–2.6 cm long, 1.8–2 cm wide between the spread basal lobes, margins ciliate and glandular papillose or coarsely verrucose, the ventral face glandular verrucose, especially toward the margins, leaving an almost longitudinally smooth central zone, basally with a transverse, truncate low callus having a verrucose surface; the labellum excavate in front of the callus, forming a shallow, conical rounded sack; the apex of the labellum callus thickened. Column green or maroon or maculated with green and maroon, straight, apically thickened, conspicuously rostrate, 16–22 mm long; clinandrium apiculate and slightly incurved apically; antennae bilaterally symmetrical, subparallel or somewhat divergent, smooth or finely glandular verrucose, 6–8 mm long. Anther yellowish green, maroon at the base and apex. Pollinia 2, cleft, waxy, yellow, compressed, more than twice as long as wide, attached to a light yellow-green stipe with a white, adhesive viscidium.

Paratypes. VENEZUELA. BOLÍVAR: Distrito Roscio, 60 km al oeste de Santa Elena de Uairén, por la vía de Icabarú, *G. Carnevali 2614* (VEN); Distrito Piar, on tributary to Río Carrao, ca. 10 mi. above Canaima and Río Churún, *G. C. K. Dunsterville 259* (line drawing, AMES).

Etymology. Named after the Río Parguaza, where the type of the species was collected.

This species has been collected several times in the Venezuelan Guayana and in Brazil (see color photograph in Miranda, 1987). In the past it had been assigned incorrectly to *C. bicallosum* Cogn. (Dunsterville & Garay, 1979: 78; Foldats, 1970: 58; Miranda, 1987), a species from the upper Río Orinoco closely related to *C. barbatum* Lindley. The type specimen of *C. bicallosum* Cogn. in the Cogniaux Herbarium (BR, photo) and the original description clearly show this affinity. *Catasetum*

parguazense belongs in the *C. callosum* Lindley alliance (Pabst & Dungs, 1975: 172). It differs from *C. callosum* by having a subcordate labellum and truncated basal callus, and it differs from *C. poriferum* Lindley (see color photo in Fergusson, 1967) by having long, fully developed antennae and a labellum with erect-patent lateral lobes. It is further distinguished by flowering almost invariably from the developing leaf shoot.

Catasetum ×dunstervillei G. Romero et Carnevali, hybr. nat. nov. inter *Catasetum pileatum* Reichb. f. et *C. discolor* Lindley. TYPE: Venezuela. Territorio Federal Amazonas: Departamento Atures, Los Oripopos, 7 km al norte de Puerto Ayacucho, 23 Nov. 1982, *G. A. Romero & A. Cortez 914* (holotype, VEN; isotype, TFAV). Figure 2H.

Planta inter parentes ad *C. discolorem* Lindley vergens, sed inflorescencia arcuata vel pendula, floribus resupinatis majoribus, labello leviter saccato, callo V-formi praedito, antennis longioribus, columnae clinandrio apiculo brevi recedit.

Plant epiphytic, indistinguishable vegetatively from other members of the genus. Staminate inflorescence lightly arcuate to pendent, racemose, to 7-flowered, originating from the base of the fully grown pseudobulb, to 16 cm long. Staminate flowers resupinate. Tepals white, maroon, light green or greenish yellow with maroon dots. Dorsal sepal concave, lanceolate, acuminate, erect, 23–25 mm long, 9–10 mm wide; lateral sepals concave, obovate, slightly oblique, apiculate, recurved, 22–25 mm long, 9–10 mm wide. Petals convex, obovate, slightly oblique, apiculate, 25–27 mm long, 11–13 mm wide. Labellum pearl white, green, light green or waxy yellow, saccate, the sack 15–18 mm deep, simple or with 2 shallow indentations alongside the apex, thus slightly trilobulate, and with a V-shaped callus near the inner apical margin; margins patent or reflexed, finely denticulate to fimbriate. Column light greenish white or yellow, semiterete, straight, apically thickened, shortly rostrate; clinandrium shortly apiculate, incurved apically; antennae bilaterally symmetrical, parallel to slightly convergent, 6–8 mm long. Anther greenish white. Pollinia 2, cleft, waxy, yellow, compressed, shorter than twice as long as wide, attached to a light yellowish white stipe with a white, adhesive viscidium.

Paratypes. VENEZUELA. TERRITORIO FEDERAL AMAZONAS: upper Orinoco, (P. Anduze) *G. C. K. Dunsterville 748* (line drawing, AMES); Departamento Atures, Río Pavoni, cerca de su confluencia con el Orinoco, 3 Nov. 1983, *G. A. Romero & J. Moreno 1153* (VEN, TFAV); same locality, 10 Aug. 1987, *G. A. Romero, P. L. Beer-Romero & J. Moreno 1336* (VEN, TFAV); Caño Rueda, 6 Dec. 1983, *G. A. Romero & L. Rojas 1158* (VEN).

Etymology. Named in honor of G. C. K. Dunsterville, who first illustrated this hybrid in his series coauthored by L. A. Garay, *Venezuelan Orchids Illustrated.*

This natural hybrid has been previously assigned to *Catasetum fimbriatum* (Morren) Lindley (Dunsterville & Garay, 1966: 42; 1979: 85; Foldats, 1970: 80). However, three lines of evidence reveal *C. ×dunstervillei* as distinct. First, northern South America lies outside the known geographical range of *Catasetum fimbriatum*: southeastern Brazil, southwestern Bolivia, Paraguay, and northern Argentina (Bicalho, 1965; Dodson, 1978). Second, typical *C. fimbriatum* from southern Brazil differs considerably from *Catasetum ×dunstervillei* in having a column with long antennae; a long, apiculate, acuminate clinandrium; an apiculate, fleshy anther; and a labellum with the fleshy mid-lobe projected forward (see Vasquez & Dodson, 1982). Third, based on fragrance and pollinator data, *Catasetum ×dunstervillei* cannot be assigned to *C. fimbriatum.* Hills et al. (1972) showed that *C. fimbriatum* is a poor fragrance producer with a fragrance spectrum unlike any other species in the genus. Moreover, the only known *C. fimbriatum* pollinator is *Eufriesea auriceps* (Friese) (Pijl & Dodson, 1966: 182). *Catasetum ×dunstervillei,* in contrast, produces a fragrance that attracts *Eulaema cingulata,* one of the pollinators of *Catasetum discolor* Lindley, *C. longifolium* Lindley, and in general the *C. maculatum* Kunth complex (Williams & Whitten, 1983). *Catasetum ×dunstervillei* was also compared with *C. fimbriatum* var. *cogniauxii* L. Linden, described from material presumably collected in Venezuela (Linden, 1895a). A plate in *Lindenia* (Linden, 1895b) and Cogniaux's sketches in the type sheet (BR, photo) reveal *Catasetum fimbriatum* differing from *C. ×dunstervillei* in the characters presented above.

Dressler (1976) pointed out that *Dunsterville 748,* assigned here to *Catasetum ×dunstervillei* (illustrated in Dunsterville & Garay, 1966: 42; 1979: 85), was a hybrid between *Catasetum pileatum* and *C. discolor,* but he never proposed a binomial. Dressler's hypothesis is supported by two lines of evidence. The flowers of *C. ×dunstervillei* are intermediate between *Catastum pileatum* and *C. discolor,* and these two species are by far more abundant than any other possible parent species

found in the general area where *C.* ×*dunstervillei* has been collected, as indicated by plant sampling and by the frequency of their pollinaria on euglossine bees (G. A. Romero, unpubl. data). Furthermore, *Catasetum pileatum* and *C. discolor* share euglossine bee pollinator and have overlapping flowering seasons.

Dodson suggested that *Dunsterville 748* was a hybrid between *Catasetum longifolium* Lindley and *C. macrocarpum* Rich. ex Kunth. (Dodson, 1978), based on plants collected in Dawa, Guyana (also pictured in Tan, 1971, fig. 8). However, the plant illustrated in Dodson (1978) differs from *C.* ×*dunstervillei* in the pendent habit, the long and narrow leaves, and the labellum morphology.

Catasetum ×*dunstervillei* is similar to *Catasetum* ×*issanensis* Pabst (a natural hybrid between *C. pileatum* and *C. longifolium*, Pabst, 1975) but is distinguished by the shorter and wider leaves and the labellum with a V-shaped callus.

Catasetum ×*dunstervillei* flowers from the mature pseudobulb from August to December. The pollen donor in *C.* ×*dunstervillei* is most likely *C. discolor*: the large pollinia of *C. pileatum* could not fit in the narrow stigmatic cleft of *C. discolor*.

Catasetum ×roseo-album (Hook.) Lindley (pro. sp.), hybr. nat. nov. inter *Catasetum discolor* Lindley et *C. longifolium* Lindley. *Monachanthus roseo-albus* Hook., Bot. Mag. 66: t. 3736. 1839. *Catasetum discolor* var. *roseo-album* (Hook.) Mansf., Repert. Spec. Nov. Regni Veg. 30: 264. 1932. TYPE: Brazil. Para: sent by Mr. Campbell to Mr. Murray at the Glasgow Botanical Garden, collector unknown (holotype, K, photo).

Selected specimens examined. VENEZUELA. BOLÍVAR: Distrito Cedeño, Agua Mena, epífita sobre *Mauritia flexuosa*, Dec. 1983 (male fl), *G. A. Romero & J. Moreno 1166* (TFAV). TERRITORIO FEDERAL AMAZONAS: Departamento Atabapo, Laja Cabezón, Río Cabezón, cerca de su confluencia con el Río Atabapo, 11 Sept. 1960 (male fl), *E. Foldats 3884* (VEN); Departamento Atures, Río Pavoni, epífita sobre árbol seco, 10 Nov. 1987 (male fl), *G. A. Romero & J. Moreno 1421* (TFAV); Río Autana, Caño Cabeza de Manteco, epífita sobre *Bactris* sp., 8 Oct. 1987 (male & female fl), *G. A. Romero & J. Moreno 1405* (TFAV); same locality and habitat, 12 Nov. 1987 (male fl), *G. A. Romero & J. Moreno 1423* (TFAV); Departamento Río Negro, Cerro Arauicaua, Río Yatua, 19 Apr. 1970 (male fl), *J. A. Steyermark & G. Bunting 102571* (VEN); same locality and date (female fl), *J. A. Steyermark & G. Bunting 102649* (VEN).

Etymology. The specific epithet probably refers to the rose and white flowers in the original description.

Natural hybrids between *Catasetum discolor* and *C. longifolium* were expected in the Venezuelan Guayana: the two species are separated by less than the flying range of euglossine bees (1–5 km), they share male euglossine bee pollinators, *Eulaema meriana* (Olivier), *E. bombiformes* (Packard), and *E. cingulata* (Fabricius), and they have overlapping flowering seasons. Around Puerto Ayacucho, Venezuela, the same species of *Eulaema* bees have been caught carrying the very distinct *C. discolor* and *C. longifolium* pollinaria in late February through May. The pollinaria of both species are placed on the ventrum of the bees' thorax, but *C. discolor* pollinaria have a dark brown stipe and a very small viscidium (narrower than the involute stipe), whereas *C. longifolium* pollinaria have a light brown stipe and a large viscidium (wider than the involute stipe). Plants bearing flowers intermediate between the two presumed parents had been collected in the Venezuelan Guayana, Guyana (Dodson, 1978), and Brazil (Mansfeld, 1932) and were assigned previously to *Catasetum discolor* var. *roseo-album* (Hook.) Mansf. Dodson (1978) suggested that this taxon may have resulted from a natural cross between *Catasetum discolor* and *C. longifolium*, but he never changed its nomenclatural status to that of nothotaxon.

Catasetum ×*roseo-album* is widespread in lowland "morichales" (gallery forest communities dominated by *Mauritia flexuosa* L.f.) in the northwestern Venezuelan Guayana, where it occupies typical *C. longifolium* habitat, growing near the crown on the stems of *Mauritia flexuosa*. It is also found on *Bactris* sp., and on dead trees in seasonally flooded forest.

The hybrid differs from *C. longifolium* by having generally erect (vs. pendulous) habit; leaves 6–20 cm long, 4–7 cm wide and generally 5-nerved (vs. 15–150 cm long, 1–3 cm wide, and 3-nerved), shortly apiculate, apically incurved (vs. obtuse and flat) clinandrium of the staminate flower, and the *C. discolor*-like pollinarium.

The hybrid differs from *C. discolor* in the epiphytic habit, generally arcuate to pendent staminate inflorescence (always erect in *C. discolor*), and deeply galeate, dorsally compressed labellum of the staminate flower (shallowly concave and globose in *C. discolor*). Pistillate flowers of the hybrid are often distinguished by the deeply galeate labellum (globose in *C. discolor*) but can vary between *C. discolor*-like to *C. longifolium*-like (deeply saccate), ranging in color from light green (yellow-green in old flowers) to deep maroon. The hybrid staminate flowers vary in color between pinkish white to green, purple, orange, or maroon.

Catasetum ×*roseo-album* flowers from the mature pseudobulb from June to January. Pollen flow between either parent is likely, as the pollinia of both species are of similar size.

Catasetum ×wendlingeri Foldats (pro sp.), hybr. nat. nov. inter *Catasetum pileatum* Reichb. f. et *C. planiceps* Lindley. TYPE: Venezuela. Territorio Federal Amazonas: Departamento Atabapo, alrededores de San Fernando de Atabapo, July 1957, *E. Foldats 2890* (holotype, VEN). Figure 2E.

Selected specimens examined. VENEZUELA. BOLÍVAR: Distrito Cedeño, Caripo, June 1980, (I. Sucre) *G. C. K. Dunsterville 1413* (line drawing, AMES); same locality, (I. Sucre) *G. Carnevali 2633* (VEN, TFAV). TERRITORIO FEDERAL AMAZONAS: Departamento Atures, Caño Rueda, 17 July 1984, *G. A. Romero & L. Rojas 1201* (VEN); carretera a Gavilán, ca. del Fundo Doña Juana, 23 June 1985, *G. A. Romero & J. Taine 1263* (TFAV); same locality, 17 May 1987, *G. A. Romero 1310* (TFAV).

Etymology. Named after K. Wendlinger, who cultivated the plant featured in the original description.

C. H. Dodson first proposed this natural hybrid between *Catasetum pileatum* and *C. planiceps* (quoted in Dunsterville & Uzcategui, 1981) based on the floral morphology of the *G. C. K. Dunsterville 1413* specimen cited above. Dodson, however, never proposed a binomial. Since then, plants resulting from the artificial cross between the presumed parents flowered in the collection of A. Pardo in Venezuela, and three more specimens of the presumed natural hybrid were collected around Puerto Ayacucho. Comparison of the staminate flower of the artificial hybrid with the holotype of *Catasetum wendlingeri* and *C. planiceps* (K, photo) showed it to be more similar to *C. wendlingeri*; in fact, some of the hybrids were identical to *C. wendlingeri*. *Catasetum wendlingeri* had been treated previously as a synonym of *C. planiceps* (Foldats, 1959; 1970: 97; Schweinfurth, 1967).

Catasetum ×*wendlingeri* differs from *C. planiceps* in the epiphytic habit and in the generally larger staminate flower with the labellum apex broadly patent or reflexed and the column with a long, apicular clinandrium. Further, the staminate flowers of the hybrid are sometimes resupinate (as in *G. C. K. Dunsterville 1413* and *G. A. Romero & L. Rojas 1201*), or the margins of the labellum are fimbriate (as in *G. C. K. Dunsterville 1413*, illustrated in Dunsterville & Uzcategui, 1981), whereas the staminate flowers of *C. planiceps* are never resupinate and the margins crenate or undulate-dentate. The hybrid differs from *C. pileatum* in the hooded labellum and the bilaterally symmetrical antennae of the staminate flowers.

Catasetum ×*wendlingeri* flowers from the developing leaf shoot from April to July. This hybrid, as is its proposed parent species, is pollinated by *Eulaema cingulata*. The pollen donor of the hybrid is most likely *Catasetum planiceps*; *C. pileatum* pollinia could not be inserted in the narrow stigmatic cleft of *C. planiceps*.

NOVELTIES IN THE LAURACEAE FROM VENEZUELAN GUAYANA[1]

Henk van der Werff[2]

ABSTRACT

Eleven new species (*Licaria tomentosa*, *Ocotea flavantha*, *O. liesneri*, *O. glabra*, *O. huberi*, *O. megacarpa*, *O. roseopedunculata*, *O. tomentosa*, *Persea croatii*, *P. croizatii*, and *P. fluviatilis*) are described. *Ocotea julianii* is published as a new name for *Phoebe steyermarkiana*, *Phoebe areolatocostae* is transferred to *Persea*, and *Ocotea steyermarkiana* is transferred to *Rhodostemonodaphne*.

During the preparation of the treatment of the Lauraceae for the *Flora of the Venezuelan Guayana*, a number of collections were found that appeared to represent undescribed taxa. Most of these collections were gathered during recent expeditions and are of high quality. As can be expected, there are, after completion of the family treatment, still several sterile or fruiting collections that do not match any of the known species from Guayana and that represent additional or even undescribed species. These species could not be included in the treatment for lack of adequate collections.

In general, the Lauraceae in Venezuelan Guayana are still undercollected. Of the 128 species (*Nectandra* excluded; this genus will be contributed by Dr. J. Rohwer), 55 are known only from one or two collections, while an additional 13 are known from three or four collections. This large number of rarely collected species suggests that there are still several additional species to be collected and that our knowledge about Lauraceae in Venezuelan Guayana is far from complete.

The available data show that about one-third of the species (41 out of 128) are endemic to Guayana. Of these 41, 31 species occur on the slopes and summits of the tepuis, while 10 are lowland species. The number of endemic lowland species will likely diminish when adjoining Colombia and Brazil are better explored, because I expect that lowland species such as *Ocotea tomentosa*, *Persea fluviatilis*, and *Phoebe semecarpifolia*, which occur near the borders with Colombia and Brazil, are not restricted to the Venezuelan side of the borders.

The new species, combinations, and the new name are arranged in alphabetical sequence.

Licaria tomentosa van der Werff, sp. nov. TYPE: Venezuela. Bolívar: Chimantá Massif, along trail from Base Camp to Bluff Camp, western slopes of Chimantá-tepui, 1,100–1,700 m, *Steyermark 75607* (holotype, NY; isotypes, COL, F). Figure 1.

Arbor, ad 10 m. Ramuli teretes, ferrugineo-tomentosi, vetustiores glabrescentes. Folia chartacea, elliptica, 8–11 × 3–4.5 cm, opposita, basi acuta, apice acuminata; supra secus costam nervosque aliquantum tomentosa; subtus ferrugineo-tomentosa. Nervi utroque costae latere 3–5, versus marginem arcuati et conjuncti. Petioli 0.5–1 cm longi, tomentosi, supra plani. Inflorescentiae floresque ignoti. Fructus ellipsoideus, 1.2 × 0.6 cm. Cupula 1.2 cm alta, 1.4 cm lata, extus laevis, margine leviter duplicata, 3 staminibus bilocellatis et 3 staminodiis praedita. Stamina vetera triangularia, locellis extrorso-apicalibus versus apicem aperientibus.

Tree, 10 m tall. Twigs terete, ferruginous tomentose, becoming glabrous with age. Leaves firmly membranaceous, elliptic, 8–11 × 3–4.5 cm, opposite, the base acute, apex acuminate, upper surface with some tomentose pubescence along the midvein and lateral veins, otherwise glabrous, the lower surface ferruginous tomentose, the tomentum wearing off with age; lateral veins 3–5 pairs, immersed above, raised on lower surface, the lateral veins arching upwards and loop-connected. Petioles 0.5–1 cm long, tomentose, not canaliculate. Inflorescence and flowers unknown. Infructescence unknown. Fruit ellipsoid, 1.2 × 0.6 cm when dry. Cupule deeply cup-shaped, 1.2 cm high and 1.4 cm broad, the outside smooth, without lenticels; the margin weakly double-margined, with traces of tomentum and bearing on the inner margin 3 2-celled stamens and 3 staminodia. Old, dried

[1] I thank the curators of F, G, MERF, MY, MYF, NY, and VEN for making their specimens available. Dr. J. Dwyer kindly checked the Latin descriptions, and John Myers drew the fine illustrations.

[2] Missouri Botanical Garden, P.O. Box 299, St. Louis, Missouri 63166-0299, U.S.A.

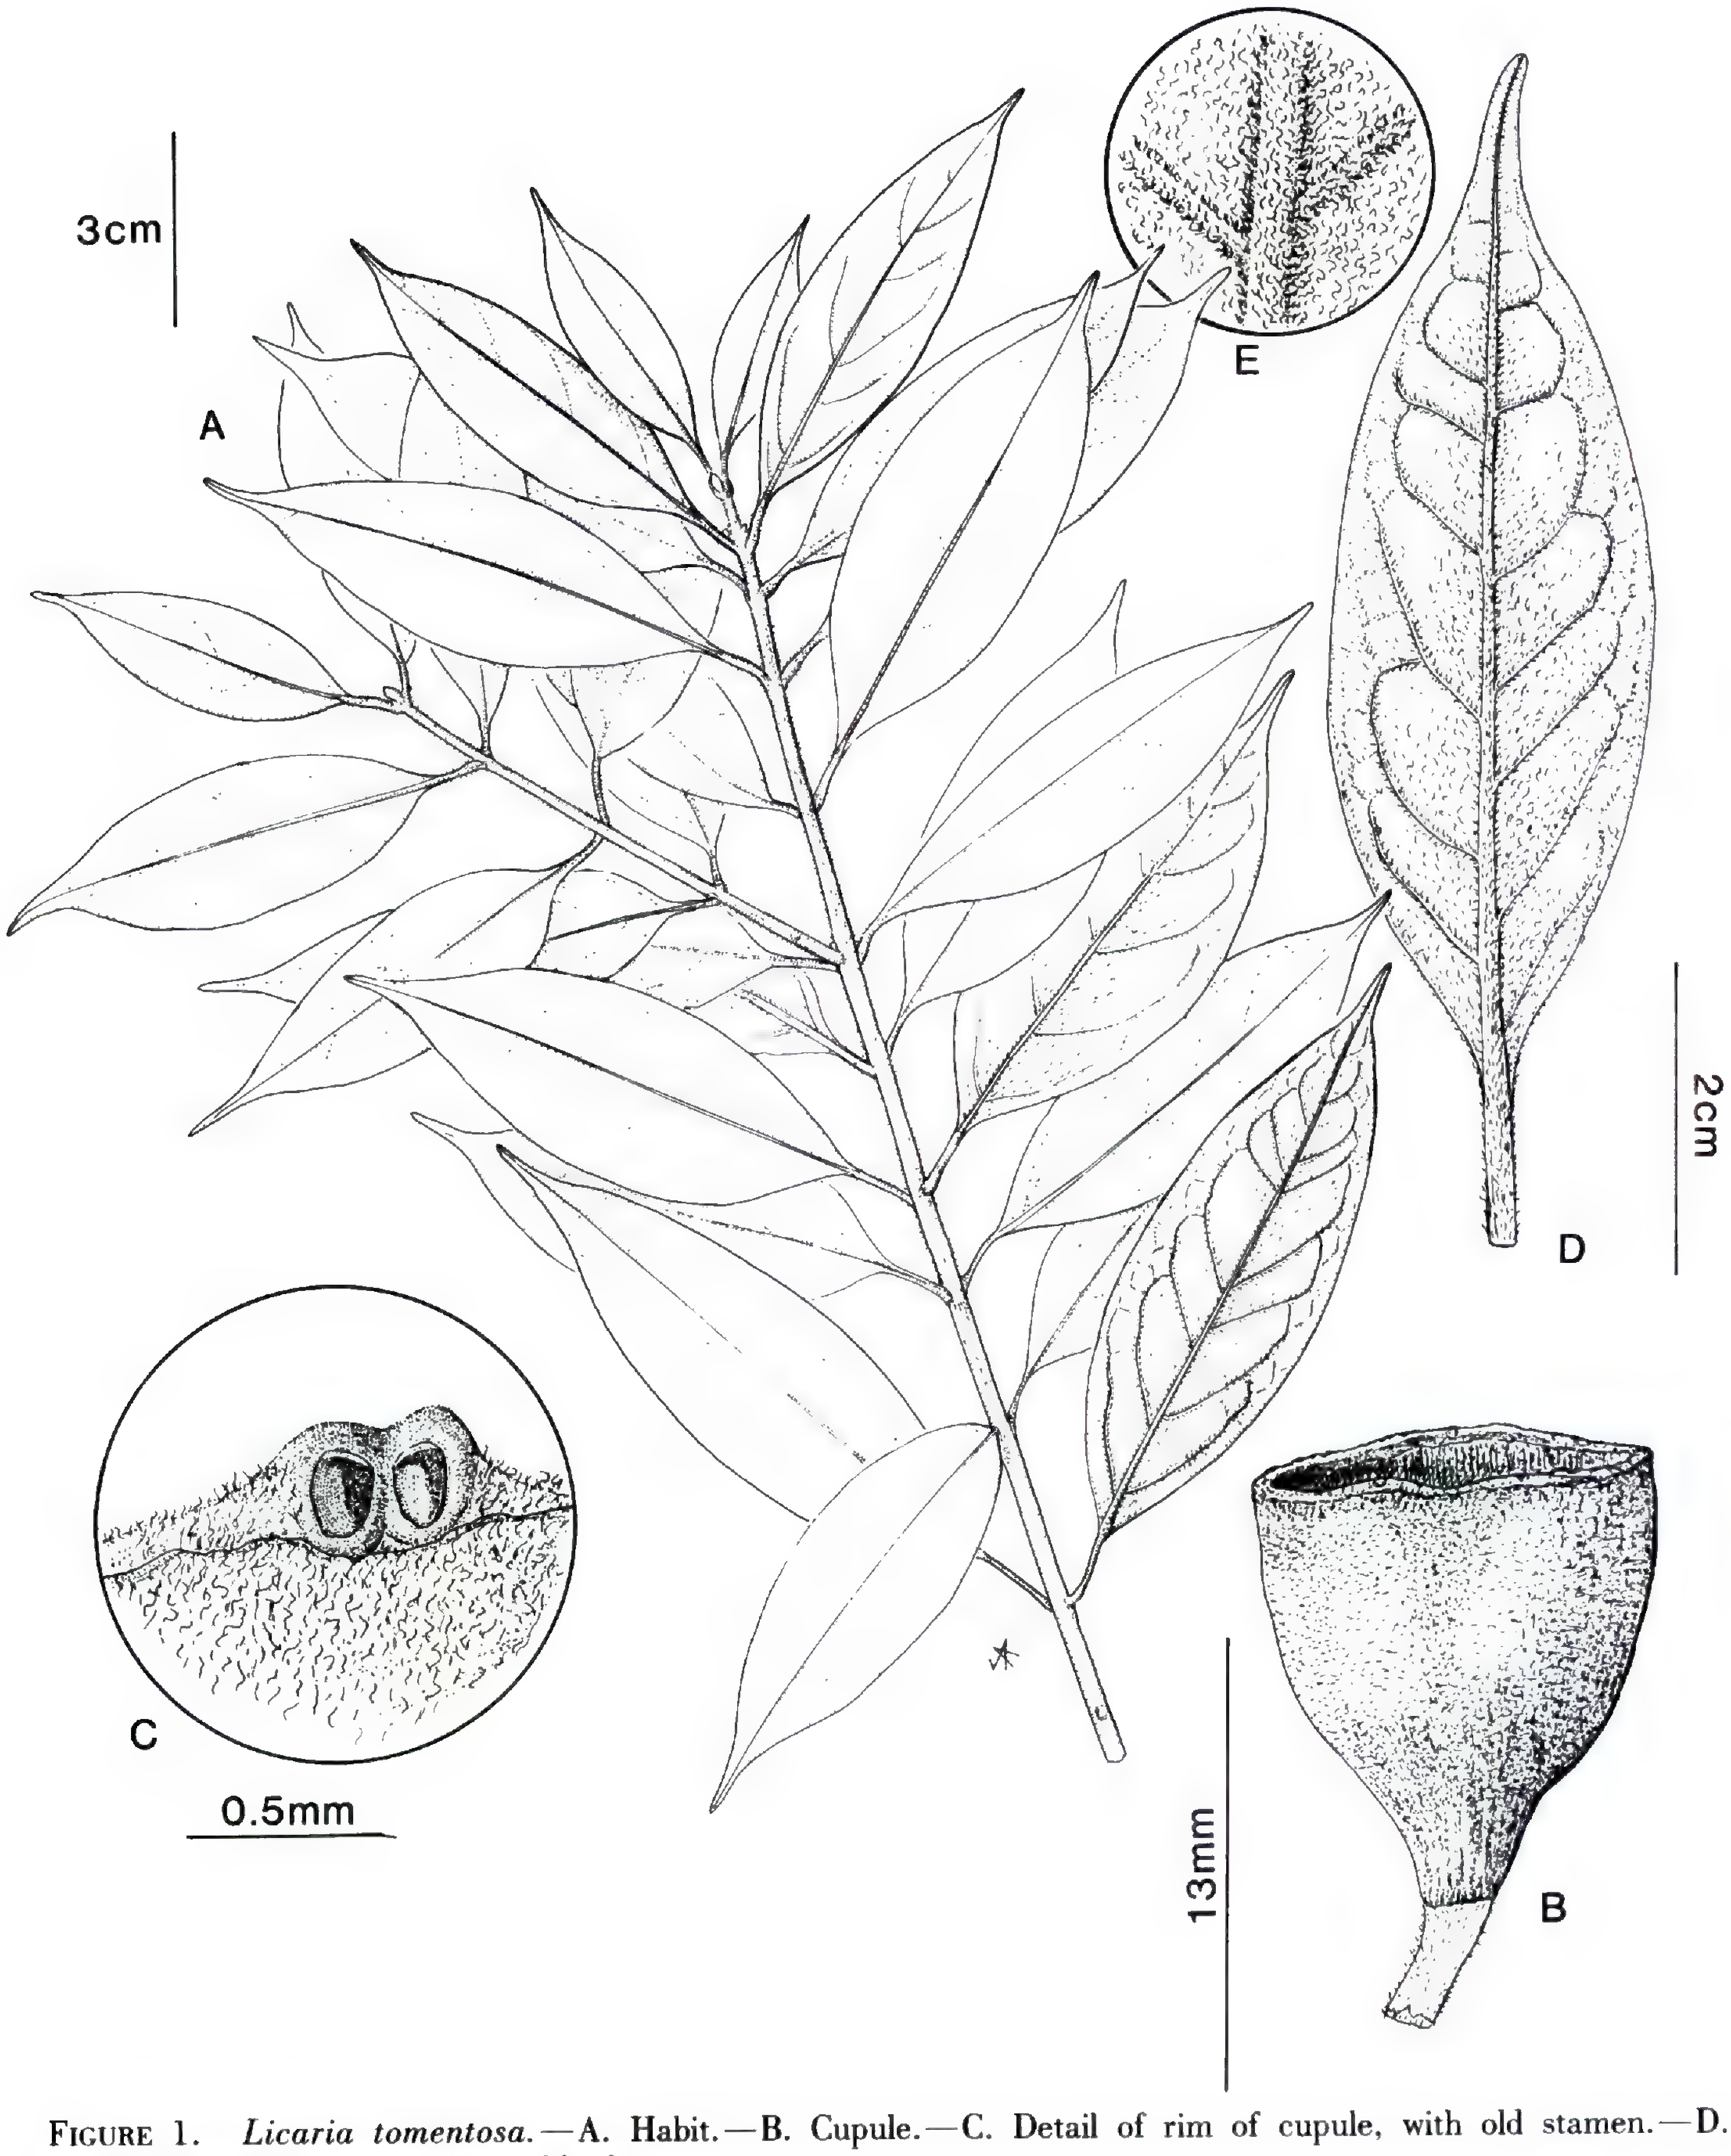

FIGURE 1. *Licaria tomentosa*.—A. Habit.—B. Cupule.—C. Detail of rim of cupule, with old stamen.—D. Leaf.—E. Detail of lower surface of leaf.

stamens triangular, the locelli extrorse-apical and opening towards the tips of the anthers. Staminodia similar in size and shape to stamens but without locelli.

Although the type collection of *Licaria tomentosa* is in fruit, the combination of characters found on the holotype leaves no doubt about the generic identity. Indicative for *Licaria* are the three 2-celled stamens, the double-rimmed margin of the cupule and the opposite leaves with few, loop-connected lateral veins which stay well away from the margin. The ferruginous-tomentose pubescence of this species readily separates it from the other *Licaria* species with opposite leaves, because these all have appressed pubescence (if any at all), usually with a lighter color.

I am not certain if *Licaria tomentosa* has only three staminodia; the staminodia present on the cupule represent whorl II and are only present when the tepals facing them have not fallen off. The tepals in front of the stamens (whorl III) are absent, and it is likely that staminodia representing whorl I would have fallen off as well.

At present, *Licaria tomentosa* is known only from the holotype in NY (with detached cupules) and sterile isotypes in COL and F. Allen (1964) identified and cited these specimens as *Ocotea roraimae* Mez, a species with alternate leaves, four-celled anthers, a canaliculate petiole, without tomentose pubescence, and lacking loop-connected lateral veins. I consider *O. roraimae* now part of *O. aciphylla* (Nees) Mez sensu lato.

Ocotea flaventha van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: Dept. Atures, valley of Río Coro-Coro, W of Serranía de Yutaje. Tree, 28 m, flowers dull golden-yellow, *Holst & Liesner 3443* (holotype, MO; isotypes, HBG, NY, VEN). Figure 2.

Arbor, ad 30 m alta. Ramuli hornotini angulati dense brunneo-tomentulosi, vetustiores teretes, indumento adpresso praediti, denique glabrescentes; partes floriferae cicatricibus conspicuis praeditae. Gemma terminalis brunneo-tomentella vel adpresse pubescens. Folia elliptica, 8 12 × 3–5 cm, coriacea, alterna, supra nitida, subtus pallide viridia, apice acuta vel breviter acuminata, basi acuta margine paulo revoluta, supra glabra, subtus paucis pilis adpressis, praesertim prope basim et secus costam, praedita. Venatio pinnata, nervis utroque costae latere 6–9, costa nervisque supra impressis, subtus paulo elevatis. Petioli adpresse brunneo-pubescentes, glabrescentes, nigricantes. Inflorescentiae brunneo-tomentellae vel adpresse pubescentes, ad 10 cm longae, paniculatae, ramulis ad apicem pluri-cymosis; inflorescentiae in axillis bractearum ad ramulorum apices foliis carentes et cicatricibus praeditas ortae. Flores unisexuales, (sub)sessiles, flavi. Tepala 6, aequalia, utrinque adpresse pubescentia, late ovata, 2.5 × 2.2 mm, sub anthesi erecta. Flos masculinus: stamina 9, 4-locellata, locellis in 2 seriebus dispositis; 6 exteriora ca. 1.6 mm longa, filamentis antheris paulo angustioribus ca. 0.8 mm longis, locellis introrsis; 3 interiora ca. 2 mm longa, filamentis ca. 1 mm longis, fere latitudine antheram aequantibus; glandulis liberis, globosis; staminodia non visa. Pistillodium ca. 2.4 mm longum, praesertim basi pubescens. Tubus floralis pubescens. Flos femineus: (partes florales super fructu juvenali praesentes): staminodia ca. 0.8 mm longa, filamento anthera perangustiore ca. 0.4 mm longo; locellis obscuris. Stylus triangularis, pubescens. Infructescentiae ad 8 cm longae. Cupula immatura profunda, lenticellata, ad 1.5 cm lata, in pedicellum attenuata.

Tree, to 30 m tall. Twigs (especially when young) angled, becoming terete with age; young twigs with a dense, short, brown tomentum, this soon becoming appressed and finally disappearing on older twigs; inflorescence-bearing parts of twigs with conspicuous scars from fallen inflorescences. Terminal bud brown-tomentellous to appressed pubescent. Leaves elliptic, 8–12 × 3–5 cm, coriaceous, alternate, smooth and lustrous above, pale green below, apex acute to shortly acuminate, the base acute with slightly revolute margin; glabrous above, with some appressed hairs below (especially near the base of the leaves and along the costa). Venation pinnate, lateral veins 6–9 pairs, costa and lateral veins impressed above, slightly raised below, a fine reticulation rarely apparent (mostly on young leaves). Petioles appressed-brown-pubescent when young, becoming glabrous and black. Inflorescences brown-tomentellous to appressed pubescent, to 10 cm long, paniculate, the branchlets usually with several cymes near their tips; inflorescences frequently arranged on leafless apical parts of twigs, these to 15 cm long and with large scars of old, fallen inflorescences, the entire complex appearing as one terminal inflorescence. Flowers unisexual, sessile or nearly so, yellow. Tepals 6, equal, appressed-brown-pubescent, broadly ovate, 2.5 × 2.2 mm, the inner surface pubescent, erect at anthesis. Male flower: stamens 9, all 4-celled, the cells arranged in 2 rows. Outer 6 stamens ca. 1.6 mm long, the filaments ca. 0.8 mm long, slightly narrower than the anthers, the cells introrse; inner 3 stamens ca. 2 mm long, the filament ca. 1 mm long and about as wide as the anther; glands free, globose, basally attached; staminodia not seen. Pistillode ca. 2.4 mm long, pubescent, especially near the base; ovary and style poorly differentiated. Floral tube pubescent inside. Pistillate flower (based on remnants found on young fruits): staminodia ca. 0.8 mm long, filament and anther ca. 0.4 mm long, filament much narrower than anther, anther cells difficult to see and not opening. Filament dorsally pubescent near the base. Style deciduous, triangular, pubescent; stigma platelike. Top of young fruit pubescent. Infructescences to 8 cm long. Floral parts persisting on young fruits, tepals slightly fused near the base and falling as a unit. Cupule deeply cup-shaped, enclosing ca. ¾ of the young fruit, lenticellate, to 1.5 cm wide, narrowed into the swollen pedicel at the base.

Paratypes. VENEZUELA. T. F. AMAZONAS: Dept. Atures, valley of Río Coro-Coro, fr, *Holst & Liesner 3402, 3421* (MO, VEN).

Ocotea flavantha is known only from the three type collections in T. F. Amazonas, Venezuela. The nearly sessile flowers, angled twigs, deep cupules, and erect tepals that tend to persist on young fruits place it in the group of *O. glomerata*. Three species

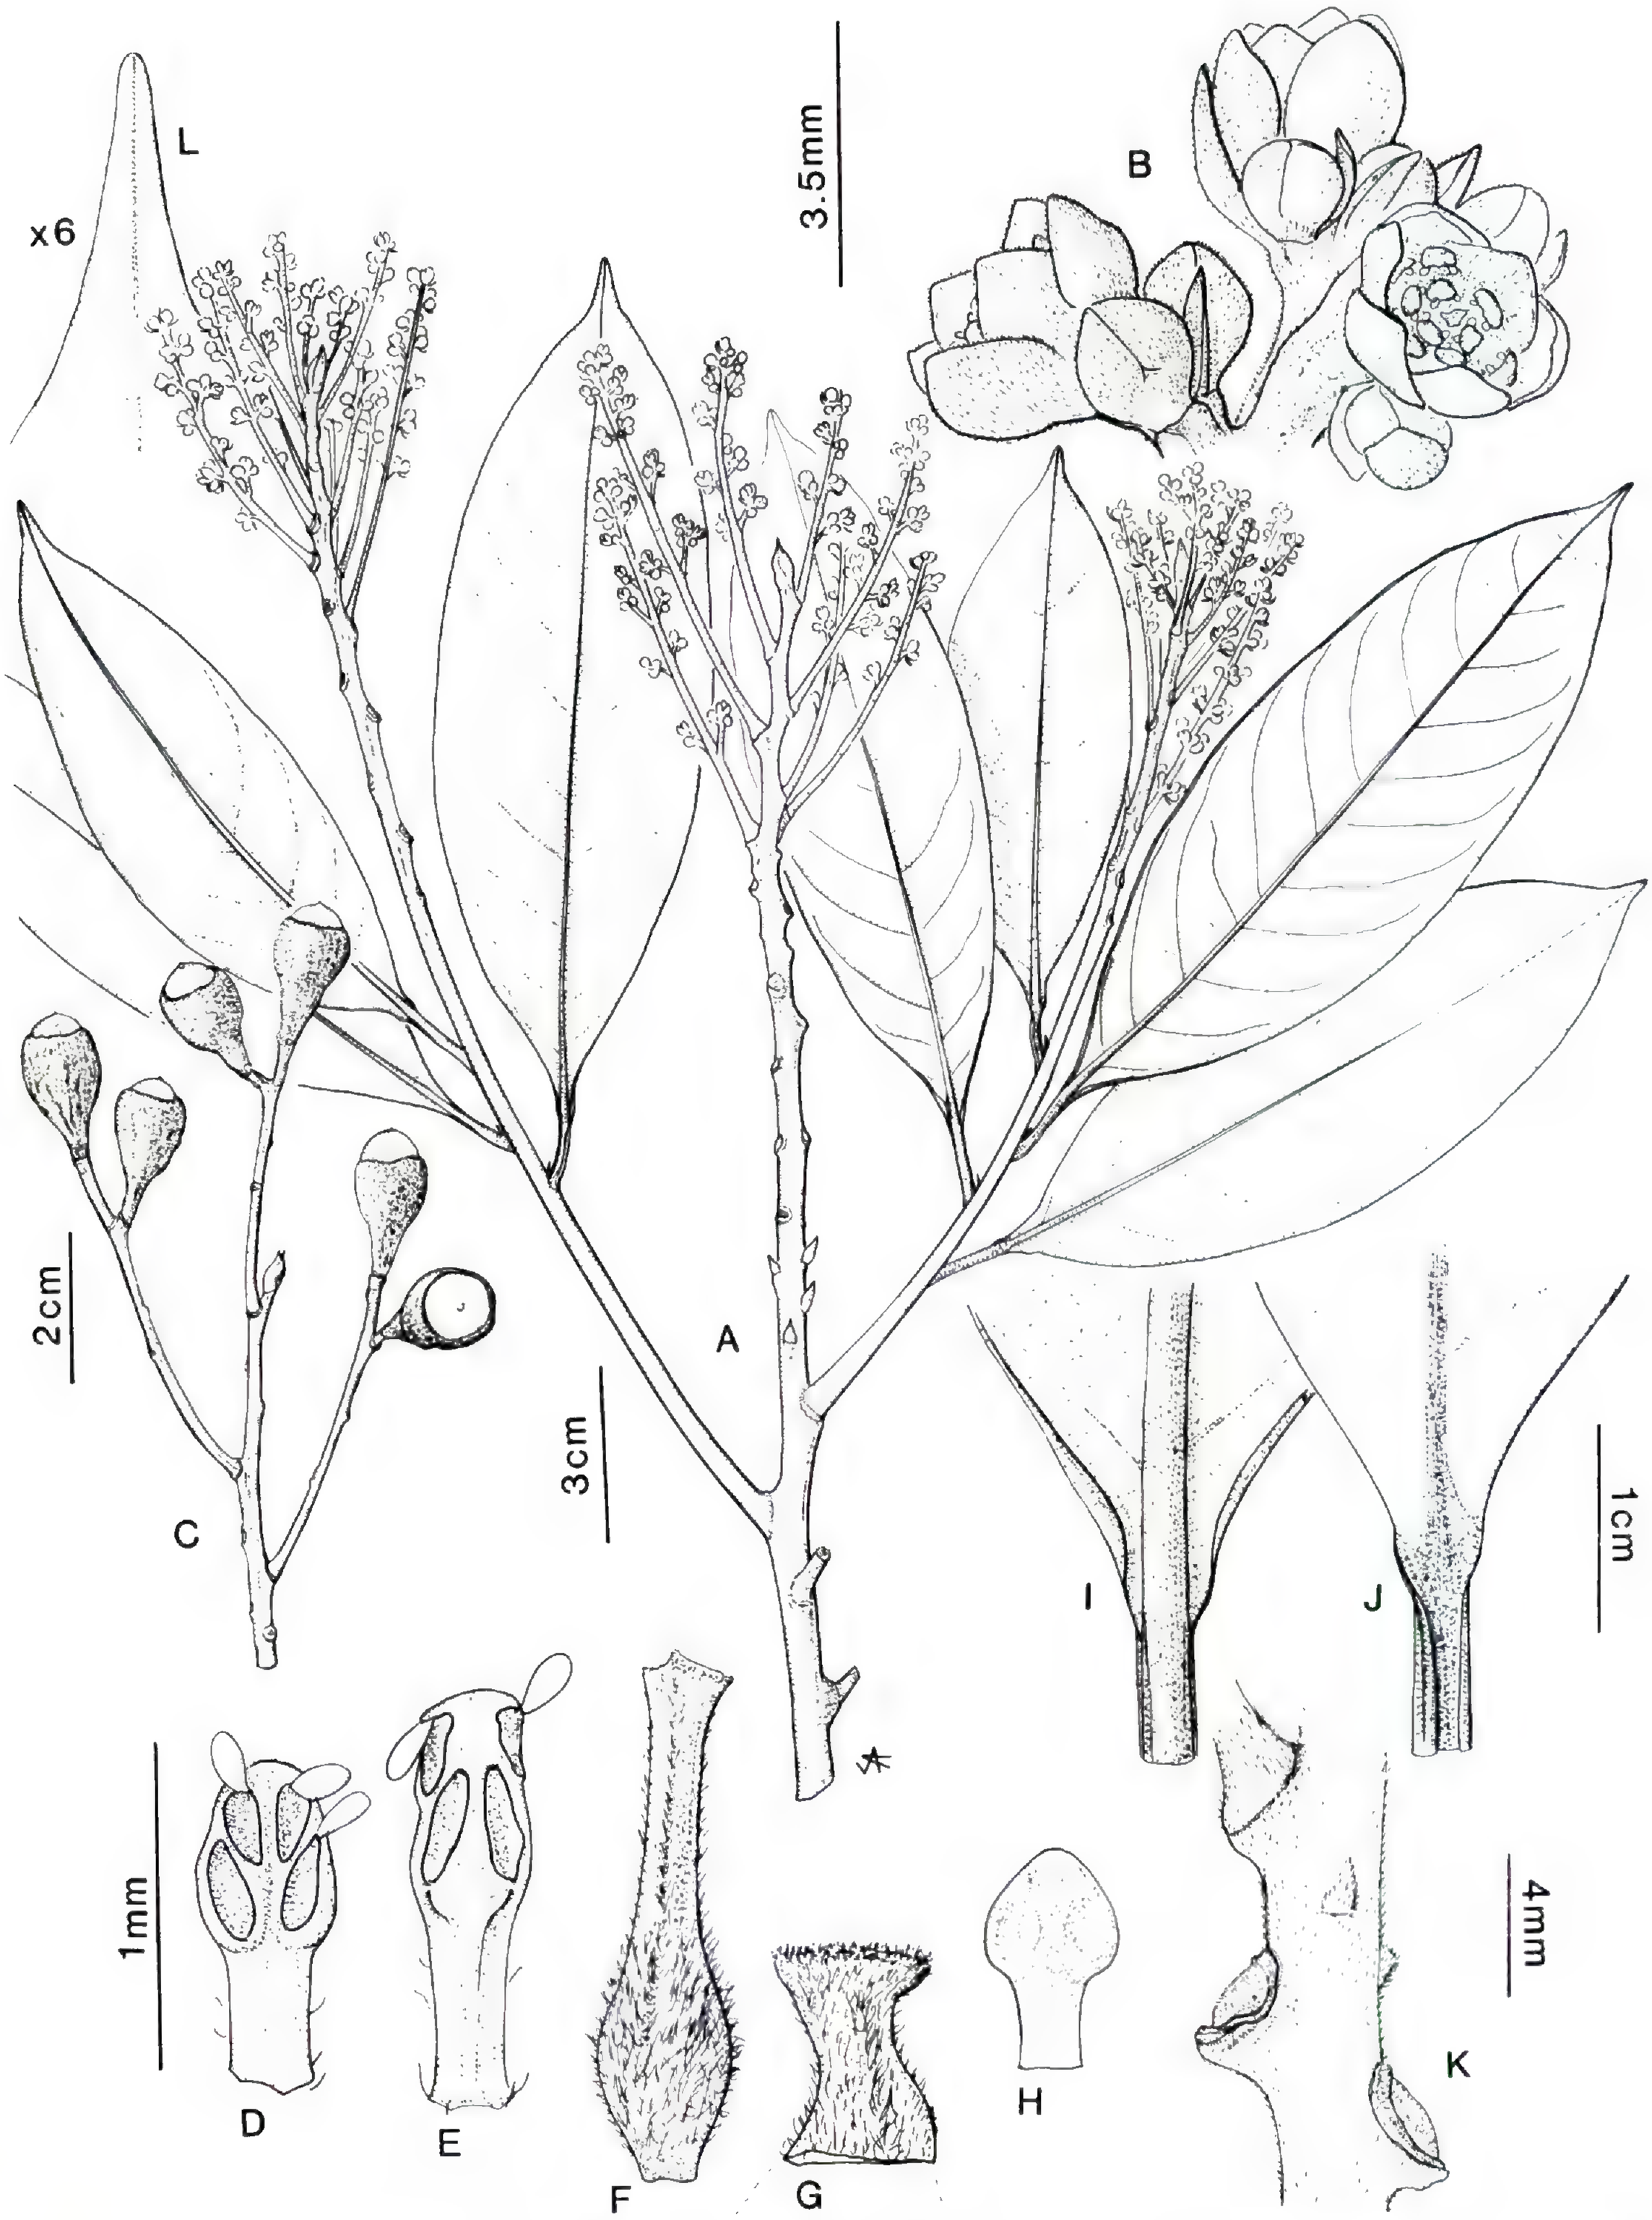

FIGURE 2. *Ocotea flavantha*.—A. Habit.—B. Flowers.—C. Young fruits.—D. Outer stamen.—E. Inner stamen.—F. Pistillode.—G. Style and stigma from young fruit.—H. Staminode.—I, J. Leaf base, seen from below and above.—K. Stem showing scars from fallen inflorescences.—L. Leaf apex.

of this group in the Venezuelan Guayana have a wide distribution (*O. glomerata* (Meissner) Mez, *O. guianensis* Aublet, and *O. longifolia* HBK), but these species have light-colored or very dense pubescence. The color of the indument and the smooth upper leaf surfaces suggest a relationship with the more restricted *O. bracteosa* (Meissner) Mez, *O. cujumary* Martius, and *O. canaliculata* (Rich.) Mez. These three species in Venezuela are known only from the eastern parts of T. F. Delta Amacuro and Estado Bolívar. *Ocotea cujumary* can be readily identified by its double-rimmed cupules; the other two species differ from *O. flavantha* in their glabrous ovary and style and in the absence of leafless, but inflorescences-carrying terminal parts of the twigs. The swollen pedicel supporting the cupule and the rather large (and still immature) cupules are additional distinctive characteristics. Differences in leaf shape are rather subtle. *Ocotea canaliculata* has the petiole poorly differentiated and lacks the weakly recurved leaf base, while *O. flavantha* has an obvious petiole and a slightly recurved leaf base. *Ocotea bracteosa* has larger and wider (to 15 × 6 cm) and more glaucous leaves than *O. flavantha*.

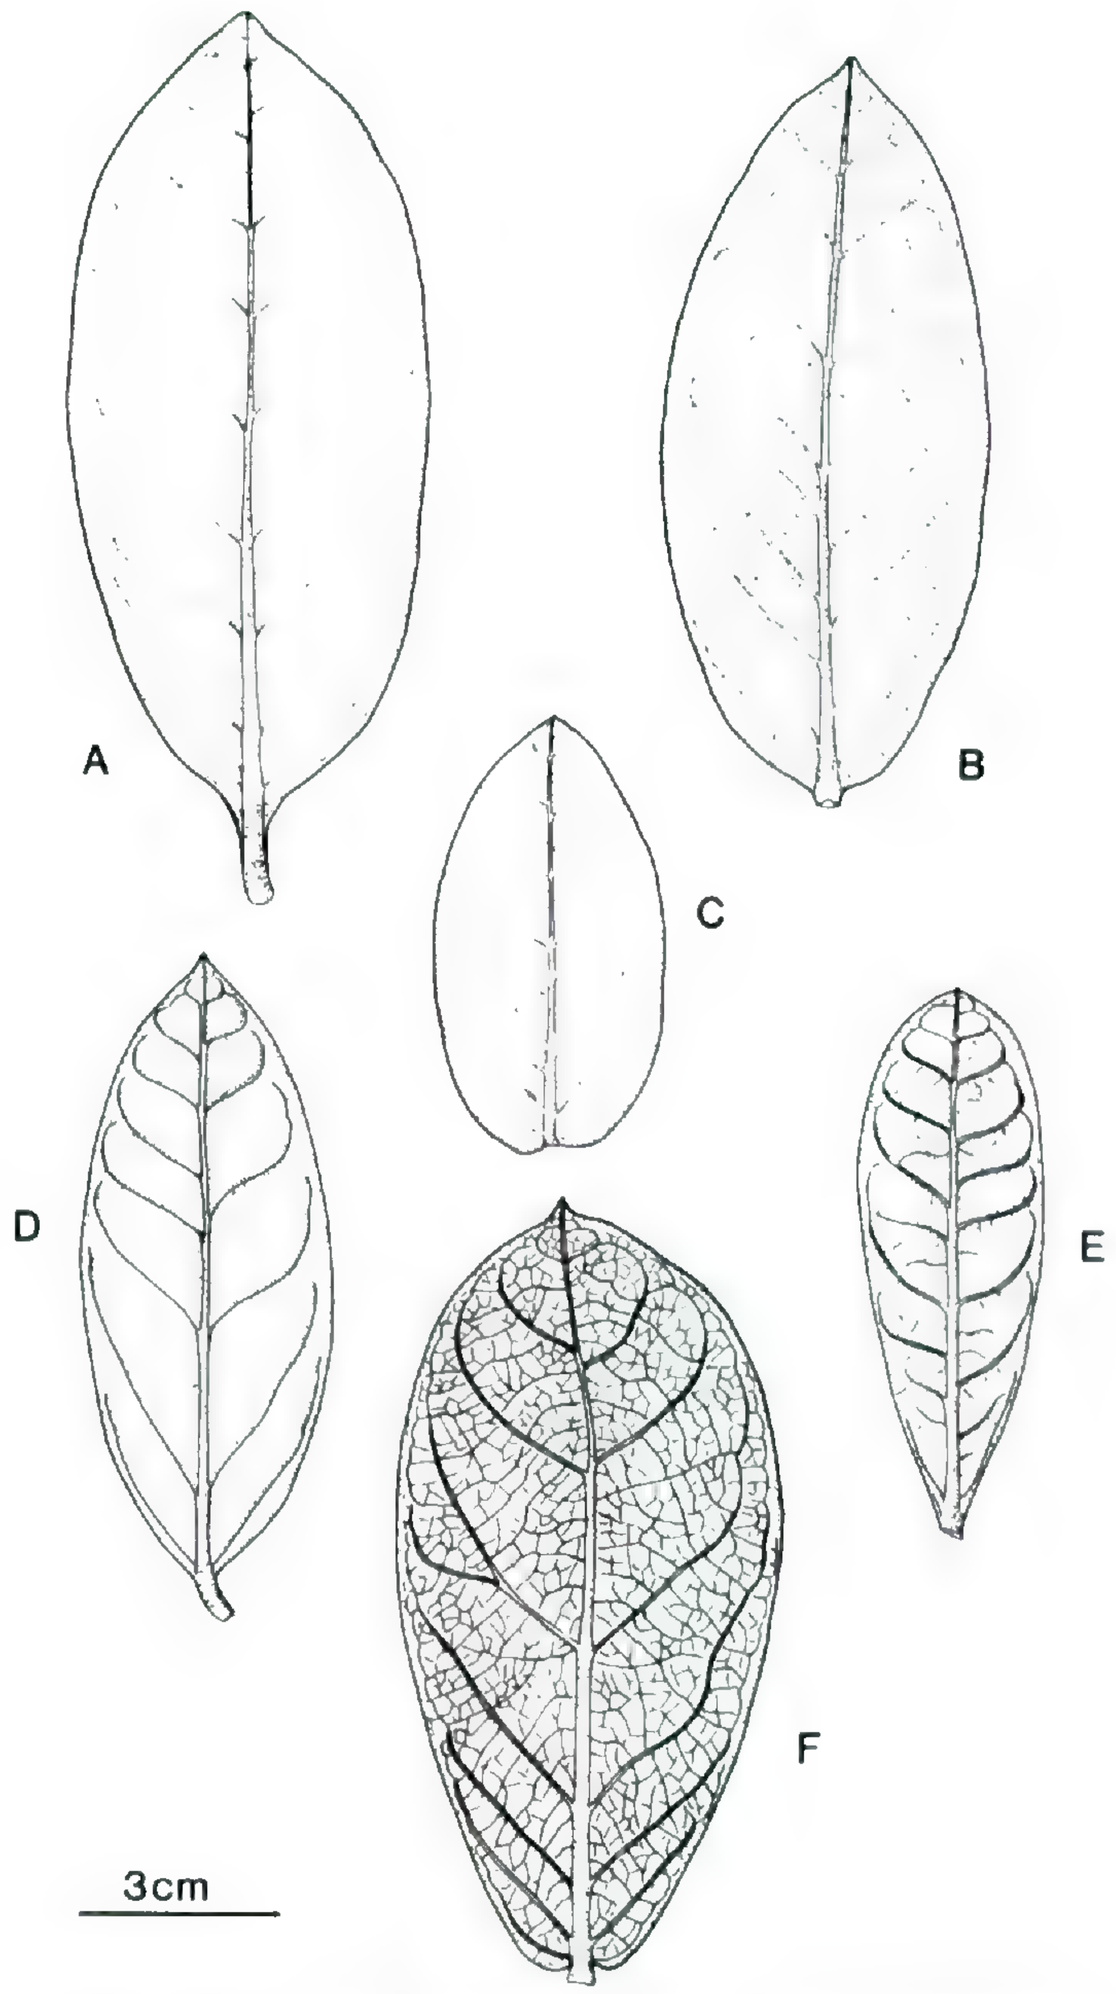

FIGURE 3. Leaf shapes of *Ocotea* species with glabrous twigs, leaves, terminal buds, inflorescences, and flowers.—A. *Ocotea cowaniana* (*Cowan 31106*).—B. *Ocotea venosa* (*Tate 676*).—C. *Ocotea erectifolia* (*Steyermark 97926*).—D. *Ocotea roseopedunculata* (*Huber 10127*).—E. *Ocotea glabra* (*Huber 12003*).—F. *Ocotea huberi* (*Huber 11008*).

Ocotea glabra van der Werff, sp. nov. TYPE: Venezuela. Bolívar: summit of Carrao-tepui, 2,470–2,500 m, shrub 4–8 ft. tall, *Steyermark 60897* (fl) (holotype, VEN; isotype, F). Figure 3E.

Frutex ad 2.5 m altus. Ramuli crassi, glabri, teretes. Gemma terminalis glabra. Folia obovata vel anguste obovata, 5–8 × 1.5–3 cm, alterna, saepe aggregata, coriacea, basi acuta, apice subacuta vel rotundata, glabra, supra polita. Venatio pinnata; nervi laterales utroque costae latere 6–9, sub angulo 70–80° prodeuntes, supra elevati, subtus quasi immersi. Petioli glabri, crassi, in sicco obscuri, ad 2 mm longi. Inflorescentiae glabrae, spicatae vel anguste paniculatae, pauciflorae, ex axillis bractearum persistentium vel infrequenter foliorum ortae. Flores unisexuales, glabri; tepala 6, aequalia, late elliptica, ca. 2 mm longa, 1.7 mm lata; flos masculinus: stamina 9, 4-locellata, glabra, 6 exteriora locellis introrsis, filamento ca. 0.6 mm longa; 3 interiora locellis inferioribus extrorsis, locellis superioribus lateralibus, filamenti base glandulis duabus connatis praedita; staminodia non visa; pistillodium lineare, ca. 0.8 mm longum; in flore femineo: staminodia ca. 0.7 mm longa, ovarium glabrum, ellipsoideum, ca. 2 mm longum, stigmate capitata. Fructus ignotus.

Shrub, to 2.5 m tall. Twigs thick, glabrous, terete, with conspicuous leaf scars. Terminal bud glabrous, usually hidden by the leaves. Leaves obovate to narrowly obovate, widest above the middle, 5–8 × 1.5–3 cm, alternate, somewhat clustered along twigs, coriaceous, the base acute, the apex very shortly acute to rounded, glabrous, the upper surface shiny, especially on young leaves, the lower surface less shiny. Venation pinnate, lateral veins 6–9 pairs, departing from the midvein under an angle of 70–80°, raised on the upper surface and immersed or nearly so on the lower surface; margin often slightly revolute. Petiole glabrous, to 2 mm long, drying dark. Inflorescences glabrous, ca. 6 cm long, few-flowered, mostly in the axils of persistent bracts, these 5–7 mm long, narrowly elliptic, glabrous. Flowers unisexual, glabrous; staminate flowers with tepals erect at anthesis; tepals 6, equal, broadly elliptic, ca. 2 mm long, 1.7 mm wide; stamens 9, 4-celled, glabrous, the outer 6 stamens with introrse cells arranged in 2 rows, filament and anther both ca. 0.6 mm long; inner

stamens with lower cells extrorse, the upper ones lateral, the base of the filament with 2 large, fused glands; staminodia not seen; pistillode present, linear, ca. 0.8 mm long; pistillate flowers with staminodia ca. 0.7 mm long, the ovary ellipsoid, ca. 2 mm long, glabrous, style lacking, stigma capitate. Fruit unknown.

Paratype. VENEZUELA. BOLÍVAR: Municipio Gran Sabana, Caraurén-tepui, ca. 1,950 m, fl, *Huber & Picon 12003* (MYF).

Ocotea glabra is known only from two collections from the summits of Carrao- and Caraurén-tepuis. It is characterized by being completely glabrous, its (narrowly) obovate leaves, and its venation with lateral veins departing at almost 90° from the midvein. This last-mentioned character occurs also in *O. wurdackiana* Allen, a species restricted to the tepuis of Estado Bolívar. Allen (1964) cited the type collection of *O. glabra* as a paratype of *O. wurdackiana* and described *O. wurdackiana* as having hermaphrodite flowers. Recent collections have shown that *O. wurdackiana* has unisexual flowers, like *O. glabra*. The two species, although superficially similar, can be separated as follows: *O. glabra* is entirely glabrous and has the lower leaf surfaces smooth, while *O. wurdackiana* always has a pubescent terminal bud, the inner surface of the tepals densely pubescent, and the lower leaf surface microscopically papillate.

Ocotea glabra has its closest relatives among the ten unisexual *Ocotea* species in the Venezuelan Guayana that share glabrous twigs, leaves, and terminal buds. Two of these have pubescent flowers or inflorescences (*O. myriantha* (Meissner) Mez and *O. perrobusta* (Allen) Rohwer) and are not very closely related. *Ocotea myriantha* is a lowland species, rather common in southern T. F. Amazonas, whereas *O. perrobusta* is restricted to Auyan-tepui, Estado Bolívar. The remaining species in this group have a restricted distribution and are known only from the upper slopes or summits of one or two sandstone mountains. Three have rather large, many-flowered inflorescences: *O. crassifolia* (Sarven-tepui, Roraima), *O. neblinae* (Neblina), and *O. basirecurva* (Serranía de Yutaje, Cerro Coro-Coro). Short, almost spicate, and few-flowered inflorescences, also strongly coriaceous leaves, characterize the last large group of species. Several but not all species in this group have glaucous, clustered, almost sessile leaves, shiny upper leaf surfaces, and lobed or toothed cupules. This group can be subdivided into (1) species from Estado Bolívar, characterized by immersed or elevated costa and lateral veins but without a raised reticulation (*O. erectifolia* (Allen) van der Werff, Cerro Jaua; *O. glabra* van der Werff, Carrao-tepui and Caraurén-tepui; *O. roseopedunculata* van der Werff, Acopán-tepui), and (2) species from T. F. Amazonas with weakly developed lateral veins and raised reticulation on upper and/or lower leaf surface (*O. venosa* Gleason, Cerro Duida, Marahuaca; *O. cowaniana* Allen, Serranía Paru; *O. huberi* van der Werff, Cerro Coro-Coro, Serranía Guanay). *Ocotea glaucophylla* Moldenke, based on material from Cerro Duida, is not well understood; to this small-leaved species also belong collections from Chimantá, revealing an unusual distribution pattern. With the exception of *O. glaucophylla*, these species are well defined by their inflorescence and leaf characters (Fig. 3); they are also geographically separated, and the paucity of collections is probably due to occurrence in inaccessible places. The collection *Maguire 33026* (NY) from Cerro Guaiquinima belongs in this species group (it has glabrous leaves, twigs, and terminal bud, and clustered, glaucous, coriaceous, subsessile leaves) and differs from the other species in its smooth upper leaf surface; it is almost certainly undescribed, but because it is sterile, I do not wish to describe it.

Ocotea huberi van der Werff, sp. nov. TYPE: Venezuela. Bolívar: Distr. Cedeño, Serranía Guanay, ca. 1,700 m, *Huber 11008* (holotype, MO; isotype, MYF n.v.). Figure 3F.

Frutex, ad 3 m altus. Ramuli glabri, juniores subangulares, vetustiores teretes. Gemma terminalis non visa, foliis obtecta. Folia elliptico-oblonga vel leviter obovata, 8–13 × 5–8 cm, coriacea, alterna, basi rotunda vel cordata, apice rotunda vel apiculata, supra polita, praesertim in foliis novellis, subtus subpolita, glauca. Venatio pinnata, nervis lateralibus utroque costae latere 6–8, prope marginem versus apicem curvatis coalitisque; costa utrinque immersa; nervis lateralibus et reticulatione elevata, sed foliis veteribus paulo elevatis. Petioli glabri, crassi, ad 3 mm longi. Inflorescentiae glabrae, flores 5–6 mm diametro; tepalis 6, aequalibus, ovatis, 2–2.2 mm longis, 1.4 mm latis, 3 interioribus pagina interiore paucis pilis praeditis, ceterum glabris; staminibus 9, 4-locellatis, eis seriei primae ca. 1.6 mm longis, antheris ca. 0.9 mm longis, locellis introrsis, filamentis ca. 0.5 mm latis, eis seriei secundae ca. 1.0 mm longis, locellis introrsis, filamentis ca. 0.2 mm latis, eis seriei tertiae ca. 1.4 mm longis, antheris rectangularibus, ca. 0.8 × 0.6 mm, locellis lateralibus, filamentis basi 2 glandulis magnis praeditis; staminodiis 3, ca. 0.5 mm longis, linearibus, basi pubescentibus; ovario ellipsoideo, ca. 1.3 mm longo, sensim in stylum brevem attenuato; stigmate capitato. Cupula non profunda, ca. 1 cm lata, margine 6-lobato vel 6-dentato, sensim in pedicellum attenuata. Fructus ovaloideus, 1.5 × 1 cm.

Shrub, 1–3 m tall. Twigs glabrous, subangular when young, becoming terete. Leaves elliptic-ob-

long to slightly obovate, 8–13 × 5–8 cm, alternate, ± evenly distributed along twigs, coriaceous, the base rounded to cordate, the apex rounded to apiculate, the upper surface shiny, especially the young leaves, the lower surface less so, glaucous. Venation pinnate, the lateral veins 6–8 pairs, curving upward towards the margin and becoming connected; midrib immersed on upper and lower surfaces, lateral veins and tertiary venation raised and forming a coarse reticulum, this less visible on older leaves. Petioles glabrous, thick, to 3 mm long, blackish when dry. Inflorescences glabrous, in the axils of persistent leaves, 12–16 cm long, exceeding the leaves, narrowly paniculate. Flowers glabrous, 5–6 mm diam.; tepals 6, equal, ovate, 2–2.2 mm long, 1.4 mm wide, the inner 3 with a few hairs on the inner surface, otherwise glabrous, reflexed in old flowers; stamens 9, the anthers 4-celled; outer 3 (whorl I) ca. 1.6 mm long, the anther ca. 0.9 mm long, cells introrse, the filament ca. 0.5 mm wide; stamens of whorl II ca. 1.0 mm long, cells introrse, the filaments ca. 0.2 mm wide; stamens of whorl III ca. 1.4 mm long, the anther rectangular, ca. 0.8 mm long, 0.6 mm wide, cells lateral; glands at base of filaments free, ca. 0.5 mm long; staminodes 3, linear, ca. 0.5 mm long, pubescent near base; ovary ellipsoid, ca. 1.3 mm long, gradually narrowed into short style, 0.3 mm long; stigma large, capitate. Cupule a shallow cup, ca. 1 cm wide, with 6 teeth or lobes at the margin and gradually narrowed into the pedicel. Fruit ovaloid, 1.5 × 1 cm fide collector.

Paratypes. VENEZUELA. T. F. AMAZONAS: Depto. Atures, cumbre del Cerro Coro-Coro, 2,200 m, *Huber 12298* (MO, MYF).

Ocotea huberi is restricted to the Departamento Atures and Distrito Cedeño, along the border of Estado Bolívar and T. F. Amazonas. Its closest relative is *O. venosa* Gleason, a species only known from the type collection from Cerro Duida and a fruiting specimen from Cerro Marahuaca, both in T. F. Amazonas. The two species have similarly raised reticulation, toothed or lobed cupules, and swollen fruiting pedicels. They differ in their leaf bases, which are obtuse in *O. venosa* vs. rounded to cordate in *O. huberi*, and in the much shorter inflorescences of *O. venosa*. The types of *O. venosa* (NY, US) do not have open flowers, and I have not compared their floral details; I accept *O. huberi* as a distinct species based on its striking leaf shape and long inflorescences.

The group of species to which *Ocotea huberi* belongs is characterized by unisexual flowers. The MO sheet of *Huber 11008* has two twigs, one in young fruit, the other in flower. Dissection showed the flowers to be staminate (anthers with well-developed locelli; pistil hollow). Thus, the flowering and fruiting twigs on the type sheet probably came from different plants, and I select the flowering twig as the holotype. Relationships of *O. huberi* are further discussed under *O. glabra*.

Ocotea julianii van der Werff, nom. nov. Based on *Phoebe steyermarkiana* Allen, Mem. New York. Bot Gard. 10(5): 74. 1964. TYPE: *Steyermark & Wurdack 921* (holotype, NY; isotypes, F, MO).

Ocotea julianii was erroneously described as belonging to the genus *Phoebe* by Allen. The large, cup-shaped cupule excludes this species at once from *Phoebe*, a genus in which the fruit is subtended by a small cupule with the tepals usually persisting. Leaf venation, the large cupule, and the deep floral tube in old flowers all point to the *Ocotea aciphylla* group (I have not seen good flowering material). Because Allen already described *Ocotea steyermarkiana*, a new epithet is needed when *Phoebe steyermarkiana* is transferred to *Ocotea*.

The similarity between *Ocotea julianii* and *Phoebe tetragona* (Meissner) Mez pointed out by Allen (1964) is superficial. Fruiting specimens of the latter species have a cupule typical of *Phoebe*, and the leaves and flowers are glabrous. Distribution also argues against a close relationship, since *P. tetragona* is a cerrado species from Minas Gerais, Brazil. I regard *O. julianii* as closely related to *O. revoluta* Moldenke, a poorly known species from Cerro Duida. This species differs in its narrower, generally smaller leaves with revolute margins and in its smaller, funnel-shaped cupules; both species belong to the *O. aciphylla* group.

Ocotea liesneri van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: Dept. Río Negro, Cerro Neblina Camp IV, 780 m, *Liesner 16687* (holotype, MO; isotypes, HBG, NY, VEN).

Arbuscula, ad 5 m altus. Ramuli teretes (novelli paulo angulati), glabri. Gemma terminalis glabra. Folia late elliptica vel late ovata, 10–17 × 7–11 cm, coriacea, alterna, apice acuta vel rotundata, basi obtusa vel rotundata, margine paulo revoluta, utrinque opaca. Venatio pinnata, nervis utroque costae latere 5–7, prope marginem versus apicem arcutis et evanescentibus; costa nervisque lateralibus supra immersis, subtus elevatis, subtus reticulatione minuta paullo elevata. Petioli glabri, 1.5–2 cm longi, parum canaliculati. Inflorescentiae glabrae, ad 10 cm longae, foliis breviores, paniculatae, ramulis basalibus 2–5-floris, apicalibus unifloris. Pedicelli glabri vel paucis pilis

praediti, 3–4 mm longi. Flores albidi, ad 4 mm diametro, tubo florale infundibuliforme, conspicuo. Tepala 6, aequalia, elliptico-ovata, ca. 1.7 mm longa, intus parte inferiore pubescentia. Stamina 9, 4-locellata, locellis 2 seriebus dispositis; 6 exteriora ca. 1.4 mm longa, filamento 0.7 mm longo, locellis introrsis, filamento pubescente; 3 interiora 1.3 mm longa, filamento 0.7 mm longo, pubescente; glandulis breviter stipitatis, 0.3 mm diametro, locellis inferioribus extrorsis, superioribus lateralibus. Staminodia 3, linearia, pubescentia, apice incrassata et glabra. Ovarium globosum, 1.1–1.2 mm in diametro, in tubo florale intus pubescente inclusum; style 0.8 mm longo, stigmate non incrassato. Fructus ignotus.

Small tree, to 5 m tall. Twigs terete or slightly angled when young, glabrous. Terminal bud glabrous. Leaves broadly elliptic to broadly ovate, 10–17 × 7–11 cm, coriaceous, glabrous, alternate, evenly distributed along twigs, the tip rounded or acute, the base obtuse or rounded, the margin slightly revolute, both surfaces dull. Venation pinnate, lateral veins 5–7 pairs, arching upwards and disappearing near the margin, midvein and lateral veins immersed on upper surface, raised on lower surface, the lower surface with a slightly raised, fine reticulation, this less visible on the upper surface. Petioles glabrous, 1.5–2 cm long, somewhat canaliculate. Inflorescences glabrous, ca. 10 cm long, shorter than the leaves, paniculate, the lower branchlets with 2–5 flowers, otherwise flowers single, the inflorescences few-flowered. Pedicels glabrous or with very few hairs, 3–4 mm long. Flowers whitish, with a few appressed hairs on the outside, 4 mm diam., floral tube funnel-shaped, conspicuous. Tepals 6, equal, elliptic-ovate, ca. 1.7 mm long, the inner surface pubescent in the lower half. Stamens 9, all 4-celled, the cells arranged in 2 rows; outer 6 ca. 1.4 mm long, both filament and anther 0.7 mm long, the cells introrse, filament rather densely pubescent; inner 3 stamens 1.3 mm long, the filament 0.7 mm long, pubescent; glands shortly stipitate, 0.3 mm diam.; lower pair of cells extrorse, the upper pair lateral. Staminodia 3, linear, ca. 0.6 mm long, pubescent, but the tip glabrous and slightly swollen. Ovary globose, 1.1–1.2 mm diam., enclosed in the well-developed floral tube, this with pubescent walls; style distinct, ca. 0.8 mm long, not widened into a distinct stigma. Fruits unknown.

Although *Ocotea liesneri*, known only from the type collection, is in all vegetative parts glabrous like *Ocotea erectifolia* and allies, these species are probably not closely related. *Ocotea liesneri* differs from the *O. erectifolia* group, for instance, by having well-developed petioles, a rather lax inflorescence (comparable to but smaller than that of *O. basirecurva*), relatively long and pubescent filaments, and flowers apparently hermaphroditic. The last-mentioned character, difficult to ascertain, needs verification from additional collections. *Ocotea liesneri* seems quite isolated. In the Venezuelan Guayana, the number of hermaphroditic *Ocotea* species is not great; most belong to the *O. aciphylla* group, which always has pubescent flowers and a quite different venation, and the *O. oblonga* group, which has entirely different leaves. The remaining species are also isolated and possess some striking characters; they include *O. rubra* Mez, *O. cymbarum* HBK, *O. esmeraldana* Moldenke, and *O. fasciculata* (Nees) Mez.

Ocotea megacarpa van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: Depto. Atabapo, Cerro Marahuaca, 1,220–1,350 m, tree, 15 m tall, *Steyermark & Holst 130610* (holotype, MO; isotype, VEN).

Arbor, ad 15 m alta. Ramuli juniores cinnamomeo-tomentosi, parum angulosi, vetustiores glabrescentes teretesque. Folia coriacea, 15–22 × 5–9 cm, alterna, elliptica, saepe conduplicata, basi obtusa vel acuta, apice acuminata; supra glabra, venatione immersa; subtus juniora cinnamomeo-tomentosa, vetustiora glabra, costa prominenti, nervis paulo elevatis. Nervi utroque costa latere 5–8, arcuati, prope marginem evanescentes. Inflorescentiae floresque ignoti. Fructus ellipsoideus, 5–6 × 3.5–4 cm. Cupula ad 4 cm lata, 1.5 cm profunda, verrucosa.

Tree, 10–15 m tall. Twigs brown-tomentose and weakly angled when young, becoming glabrous and terete with age. Leaves stiff, leathery, 15–22 × 5–9 cm, alternate, elliptic, frequently conduplicate, the base obtuse or acute, the apex acuminate, the upper surface glabrous and with the venation immersed, the lower surface brown-tomentose when young, glabrous with age, the midvein prominent, lateral veins slightly raised, in 5–8 pairs, arching upwards and fading away close to the margin. Petioles 1.5–2 cm long, canaliculate, brown-tomentose when young, glabrescent with age. Inflorescences and flowers unknown. Infructescences with few fruits, glabrous, to ca. 7 cm long. Fruit ellipsoid, 5–6 cm long, 3.5–4 cm wide. Cupule (immature) a cup ca. 3 cm wide and 1.5 cm deep, the outside ridged and warty, the inside glabrous or with a few appressed hairs; mature cupules shallower, 3.5–4 cm wide and to 1.5 cm deep, the outside ridged and warty.

Paratypes. VENEZUELA. T. F. AMAZONAS: Depto. Atabapo, Cerro Marahuaca, 1,140 m, *Steyermark & Holst 130555* (MO, VEN); same locality, 1,225 m, *Liesner 17732, 17733* (MO, VEN).

Ocotea megacarpa is known only from three fruiting collections from Cerro Marahuaca. Leaf

shape, venation, canaliculate petioles, and the initially deep cups all point to the *Ocotea aciphylla* group. Within this group (and within the genus *Ocotea*), the large fruits and large, shallow cupules are unmatched, and *O. megacarpa* is solely described on the distinctiveness of its fruits and cupules. In the *Ocotea aciphylla* group, *O. julianii* also has large fruits (3.5 × 3 cm) and cupules (ca. 3 cm wide). However, in addition to its smaller fruits and cupules, *O. julianii* differs in its rounded to subcordate leaf bases, short, thick petioles, and blunt to rounded leaf apices. *Ocotea megacarpa* is in leaf shape (but not in indumentum) very similar to *O. aciphylla* (Nees) Mez s.l., especially to the lowland populations in T. F. Amazonas, which have been identified as *O. costulata* (Nees) Mez in the past, but this species has appressed pubescence, cupules to 2 cm wide, and fruits to 2.5 cm long.

Ocotea roseopedunculata van der Werff, sp. nov. TYPE: Venezuela. Bolívar: Distr. Piar, summit area of Acopán-tepui, ca. 1,950 m, fl, *Huber, Ahti & Pipoly 10127* (holotype, MO; isotype, MYF n.v.). Figure 3D.

Frutex ad 2.5 m altus. Ramuli glabri, cristati petiolis decurrentibus, foliorum cicatricibus conspicuis praediti. Gemma terminalis glabra. Folia elliptica vel anguste elliptica, raro subovata vel subobovata, 7–11 × 2.5–4.0 cm, coriacea, glabra, basi apiceque acuta, alterna sed plerumque conferta, foliis paucis et minoribus inter folios confertos, supra polita, subtus opaca, glauca. Venatio pinnata, nervis utroque costae latere 6–10, basalibus adscendentibus sed distalibus angulo obtuso prodeuntibus, prope marginem versus apicem curvatis et coalitis; costa nervisque lateralibus supra elevatis sed reticulatione (fere) immersa; subtus venatione quasi immersa. Petioli crassi, glabri, ad 5 mm longi, in sicco nigri. Inflorescentiae glabrae, roseae, folios aequantes vel eis paulo longiores, ex axillis foliorum vel bractearum ortae. Pedicelli glabri, ad 5 mm longi, basi bractea lineare ad 0.5 mm longa praediti. Flores glabri, flavi. Tepala 6, aequalia, ovata, 2.5 × 1.8 mm. Stamina 9, 4-locellata, locellis in 2 seriebus dispositis; 6 exteriora subsessilia, filamentis ad 0.3 mm longis, anthera 1.3 × 1.1 mm, locellis introrsis; 3 interiora ca. 1.5 mm longa, anthera ca. 1 mm longa, locellis lateralibus vel laterali-extrorsis, glandulis magnis, liberis, ca. 0.6 mm in diametro; staminodia non visa; pistillodium parvulum, lineare, ad 0.3 mm longum. Flores feminei et fructus ignoti.

Shrub, to 2.5 m tall. Twigs ridged due to decurrent leaf bases and with conspicuous scars from fallen leaves. Terminal bud glabrous. Leaves elliptic to narrowly elliptic, or rarely somewhat ovate or obovate, 7–11 × 2.5–4.0 cm, coriaceous, glabrous, base and tip acute, alternate, mostly clustered, the few leaves between the leaf clusters usually smaller, the upper surface shiny, the lower surface dull, glaucous. Venation pinnate, lateral veins 6–10 pairs, the basal ones ascending, the middle and distal ones leaving the midvein under blunter angles, near the margin curving upwards and becoming loop-connected, midvein and lateral veins raised on the upper surface but not on lower, tertiary venation immersed or nearly so on both sides. Petioles thick, glabrous, to 5 mm long, black when dry. Inflorescences glabrous, pink, about as long as the leaves or slightly longer, spicate or the lower branches with 2 or 3 flowers, in the axils of leaves or bracts. Pedicels glabrous, to 5 mm long, with a linear bract ca. 0.5 mm long at the base. Flowers yellow, glabrous. Tepals 6, equal, ovate, 2.5 × 1.8 mm. Stamens 9, all 4-celled and the cells arranged in 2 rows; outer 6 stamens sessile or nearly so, the filament to 0.3 mm long, the anther 1.3 × 1.1 mm, cells introrse; inner 3 stamens ca. 1.5 mm long, anther ca. 1 mm long, the cells lateral or lateral-extrorse, glands large, free, ca. 0.6 mm diam.; staminodia not seen; pistillode very small, linear, ca. 0.3 mm long, completely hidden by stamens and glands, stigma not developed. Pistillate flowers and fruits not known.

Paratype. VENEZUELA. BOLÍVAR: Distr. Piar, summit area of Acopán-Tepui, ca. 1,950 m, fl, *Huber, Ahti & Pipoly 10120* (MO).

Ocotea roseopedunculata is restricted to Acopán-tepui and is currently known from only two collections. Its nearest relative is *Ocotea glabra*, known from Carrao and Caraurén-tepuis in Estado Bolívar. These two species are best separated by their leaf characters: *O. roseopedunculata* has elliptic leaves with mostly ascending lateral veins, while *O. glabra* has (narrowly) obovate leaves with the lateral veins leaving the midrib under a blunter angle and more rounded leaftips. In addition, there are some small floral differences: in *O. glabra* the filaments and anthers of the outer stamens are about equally long and the pistillode is ca. 0.8 mm long; in *O. roseopedunculata* the anthers are subsessile and the pistillode is smaller, 0.3 mm long. The two species share ridged stems, conspicuous leaf scars, almost spicate, few-flowered inflorescences, and a tendency toward clustered leaves. See also discussion under *O. glabra*.

Ocotea tomentosa van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: San Carlos de Río Negro, IVIC main study site, km 4.3 on Solano Road, small tree 3 m high, flowers white, *Clark & Maquirino 6802* (holotype, MO; isotypes, HBG, NY).

Frutex vel arbor parva, ad 3 m alta. Ramuli angulati, hornotini brunneo-tomentosi, vetustiores tomentelli, de-

nique glabrescentes. Gemma terminalis brunneo-tomentosa. Folia elliptica, 15–25 × 6–8 cm, alterna, coriacea, supra praeter pubescentiam basi costae glabra, subtus secus costam nervisque pilis curvatis brunneis praedita et lamina albo-tomentosa vel cinereo-tomentosa; basi apiceque acuta, nervis utroque costae latere 6–8, sursum curvatis et nervo superiore consociatis; venatione supra immersa, costa et nervis subtus elevatis, indumento brunneo venationis tomento albido laminae discrepante. Petioli ca. 1.5 cm longi, brunneo-tomentelli vel subglabri. Inflorescentiae axillares, brunneo-tomentosae, ad 10 cm longae, paniculatae. Pedicelli ca. 1 mm longi, tomentosi. Flores (tantum feminini visi) albi. Tepala 6, aequalia, ovata, ca. 1 mm longa, extus pilis paucis cinereis praedita et minus pubescentia quam inflorescentia, intus subglabra; staminodia 9, ca. 0.3 mm longa, glabra; ovarium ca. 1 mm diametro, stylum inconspicuum, stigma capitatum. Fructus globosus, ca. 1 cm diametro, cupula non profunda, pedicello incrassato, petalis persistentibus.

Shrub or small tree, to 3 m tall. Twigs angular, brown-tomentose when young, becoming tomentellous and finally glabrous. Terminal bud brown-tomentose. Leaves elliptic, 15–25 × 6–8 cm, alternate, coriaceous, glabrous above except some pubescence on midrib, the lower surface with brown curled hairs along midrib and main veins, the leaf tissue white-tomentose, turning grayish with age, base and apex acute, lateral veins 6–8 pairs, these arching upwards and becoming loop-connected with the distal vein; venation immersed on the upper surface, costa and lateral veins raised on lower surface, the venation with brown indumentum contrasting with the white tomentum on the laminar tissue. Petioles ca. 1.5 cm long, brown-tomentellous to glabrous. Inflorescences axillary, brown-tomentose, to 10 cm long, paniculate. Pedicels ca. 1 mm long, tomentose. Flowers white (only pistillate seen). Tepals 6, equal, ca. 1 mm long, ovate, with some gray hairs on the outside and pubescence on tepals much less than on inflorescence or pedicels; inside of tepals with a few hairs or glabrous; staminodia 9, ca. 0.3 mm long, glabrous; ovary ca. 1 mm diam., style not evident, stigma capitate. Fruit a globose berry, ca. 1 cm diam., the cupule shallow, pedicel swollen and the petals persisting as lobes on the margin of the cupule.

Paratypes. VENEZUELA. T. F. AMAZONAS: San Carlos de Río Negro, IVIC main study site, fl, *Clark & Maquirino 8216* (MO); Río Guainía, ca. 7 km N of Maroa, frequent in shrub savanna, fr, *Maguire et al. 41755* (NY).

Ocotea tomentosa is known only from the upper drainage of the Río Negro between Maroa and San Carlos de Río Negro. Although the area around San Carlos de Río Negro has been reasonably well explored, *O. tomentosa* has only been collected there twice (both collections from the same marked tree) and is apparently rare. It is very likely present in Colombia and can be expected in Brazil.

The angled twigs, somewhat clustered flowers and, above all, scarce pubescence on the tepals in comparison with that on the inflorescence point to the *Ocotea leucoxylon* group as the closest relatives. None of the species in that group has leaves with dense abaxial tomentum or such persistent tepals in the fruiting stage; moreover, *O. tomentosa* lacks the white lenticels on the cupule that so readily identify the *O. leucoxylon* group.

Persea areolatocostae (Allen) van der Werff, comb. nov. BASIONYM: *Phoebe areolatocostae* C. K. Allen, Mem. N.Y. Bot. Gard. 10: 75. 1964.

The type collection of *Phoebe areolatocostae* has buds and immature fruits. However, the fruits are diseased; the relatively long petioles, leaf shape, and leaf reticulation all point to the genus *Persea*. The equal tepals are a character infrequently found in *Persea*; *P. americana* and a few related species share this character, but *P. areolatocostae* is probably not related to those species. In my opinion, the relationship is with a small group of species characterized by equal tepals, a small, round fruit, and persistent tepals in the fruiting stage. This group includes the neotropical *P. steyermarkii*, *P. rigens*, *P. silvestris*, and a few additional, as yet undescribed, species. It is not yet clear to which degree this group is related to the Asian *Persea* subg. *Machilus*.

Persea croatii van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: Cerro Neblina, near Cañon Grande at Camp No. 7, ca. 1,800 m, *Croat 59519* (holotype, MO).

Arbor, ad 4 m. Ramuli teretes, sparse adpresse pubescentes, vetustiores glabri. Folia alterna, subcoriacea, elliptica, 7–10 × 2–3 cm, basi acuta, apice obtusa; supra glabra, subtus adpresse pubescentia, sed superficie foliorum pubescentia non occulta, costa nervisque supra immersis, subtus costa elevata sed nervis immersis vel perpaulo elevatis. Petioli canaliculati, 1–2 cm longi, glabri vel leviter adpresse pubescentes. Inflorescentia axillaris, subterminalis, paniculata, ca. 12 cm longa, adpresse cinereo-pubescens. Pedicelli ca. 4 mm longi. Tepala 6, inaequalia, 3 exteriora ca. 4 mm longa, (anguste) ovata, extus pubescentia, intus glabra; 3 interiora ca. 6 mm longa, anguste ovata, utrinque adpresse pubescentia. Stamina 9, 4-locellata; 6 exteriora 4.5–5 mm longa, locellis introrsis, filamentis pubescentibus, antheris glabris, ca. 1.6 mm longis; 3 interiora locellis lateralibus vel laterali-extrorsis, filamentis pubescentibus, ca. 3 mm longis, basi 2 glandulis praeditis, antheris glabris, ca. 1.5 mm longis; staminodia 3, ca. 1 mm longa, sagittata, pubescentia. Ovarium glabrum vel apice paucis pilis praeditum,

globosum, ca. 1.5 mm diametro; stylo ca. 3 mm longo, pubescente. Fructus ignotus.

Tree, 4 m tall. Twigs terete, sparsely appressed pubescent, becoming glabrous with age. Leaves alternate, subcoriaceous, elliptic, 7–10 × 2–3 cm, evenly distributed along twigs, the base acute, apex obtuse; glabrous on the upper surface, appressed pubescent below, but pubescence not obscuring the leaf surface; costa and lateral veins (6–9 pairs) immersed on upper surface; costa raised on lower surface, lateral veins immersed or very slightly raised on lower surface. Petioles canaliculate, 1–2 cm long, glabrous or with some appressed hairs. Inflorescence axillary, pseudoterminal, paniculate, ca. 12 cm long, appressed gray-pubescent. Pedicels ca. 4 mm long. Tepals 6, unequal; outer 3 ca. 4 mm long, ovate to narrowly ovate, appressed pubescent outside, glabrous inside; inner 3 ca. 6 mm long, narrowly ovate, appressed pubescent on both surfaces. Fertile stamens 9, 4-locellate, the outer 6 with introrse cells, 4.5–5 mm long, filaments densely pubescent, anthers glabrous, ca. 1.6 mm long; inner 3 stamens with lateral or lateral-extrorse cells, 4.5–5 mm long, the filaments ca. 3 mm long, densely pubescent, each with 2 glands attached near the base, anthers glabrous, ca. 1.5 mm long. Filaments of all stamens about as wide as anthers or slightly narrower. Staminodia 3, ca. 1 mm long, sagittate, pubescent. Ovary globose, ca. 1.5 mm diam., glabrous except for some hairs near the tip; style ca. 3 mm long, pubescent.

Persea croatii is known from only one collection from the upper slope of Cerro Neblina. The pubescent style and the few apical hairs on the ovary place it in Kopp's (1966) section *Aurataea*, which includes two other species from the Venezuelan Guayana. *Persea grandiflora*, known from the lower slopes of Cerro Neblina, differs in having larger flowers, prominently raised lateral veins on the lower leaf surface, ovate (vs. elliptic) leaves, and much denser pubescence. *Persea maguirei* differs in having smaller leaves, denser pubescence which covers the lower leaf surface, shorter, more slender inflorescences with smaller flowers, and smaller floral parts. In general appearance *P. croatii* is quite similar to *P. perseiphylla*, but *P. croatii* differs in its sparser, noncupreous pubescence on the lower leaf surface and its noncupreous pubescence on flowers and inflorescence.

Persea croizatii van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: upper Río Orinoco, *Croizat 918* (holotype, F). Figure 4.

Arbor vel frutex. Ramuli teretes, juvenales sparse adpresse pubescentes, glabrescentes. Folia alterna, elliptica, 9–14 × 4–6 cm, firme chartacea, margine paulo reflexa, base apiceque acuta, supra glabra, subtus pilis adpressis praedita, praecipue secus costam nervosque; nervis lateralibus utroque latere 5–6; costa et nervis lateralibus supra immersis, subtus elevatis. Petioli plus minusve glabri, 2–3 cm longi. Inflorescentiae anguste paniculatae, 10–15 cm longae, adpresse pubescentes. Pedicelli ca. 2 mm longi, adpresse pubescentes. Tepala 6, inaequalia; 3 exteriora late ovata, intus glabra, ca. 3 mm longa; 3 interiora ovata, intus adpresse pubescentia, 5–6 mm longa. Stamina 9, 4-locellata; 6 exteriora locellis introrsis, ca. 2 mm longa, filamentis pubescentibus, ca. 1.1 mm longis, antheris glabris, ca. 0.9 mm longis, filamentis quam antheris angustioribus; 3 interiora locellis lateralibus vel extrorsis, ca. 2.5 mm longa, filamentis pubescentibus, basi 2 glandulis praeditis, ca. 1.9 mm longis, antheris glabris, ca. 0.6 mm longis, paulo latioribus quam filamentis; staminodia 3, pubescentia, sagittata, ca. 1.1 mm longa. Ovarium glabrum, globosum; stylo gracile, ca. 1.6 mm longo. Fructus globosus, ca. 8 mm diametro; tepala persistentia, patentia.

Woody plant of unknown size. Twigs terete, with some appressed pubescence when young, soon becoming glabrous. Leaves alternate, elliptic, 9–14 × 4–6 cm, firmly chartaceous, the margin slightly reflexed, base and apex acute, glabrous above, with some appressed hairs below, especially along midvein and lateral veins, or almost glabrous, lateral veins 5–6 pairs; midvein and lateral veins immersed above, raised on lower surface; final reticulation not or very slightly raised. Petioles glabrous or with a few appressed hairs especially near the base, 2–3 cm long. Inflorescences narrowly paniculate, 10–15 cm long, about as long as the subtending leaves, appressed pubescent. Pedicels ca. 2 mm long, pubescent. Tepals 6, unequal; outer 3 broadly ovate, appressed pubescent outside, glabrous inside, ca. 3 mm long, inner 3 appressed pubescent on both surfaces, ovate, 5–6 mm long; tips of inner tepals often breaking off in old flowers or in fruiting stage. Fertile stamens 9, all 4-celled; those of the outer 2 whorls with introrse cells, ca. 2 mm long, the filaments pubescent, 1.1 mm long, the anther glabrous, ca. 0.9 mm long, the filaments distinctly narrower than the anthers; inner 3 stamens linear, ca. 2.5 mm long, the filaments pubescent, ca. 1.9 mm long, with 2 globose glands attached slightly above the base, the anther glabrous, ca. 0.6 mm long, slightly wider than the filament; staminodia 3, pubescent, ca. 1.1 mm long, sagittate. Ovary glabrous, style slender, ca. 1.6 mm long, stigma platelike. Fruit globose, ca. 8 mm diam., with glaucous bloom; tepals persistent, spreading.

Persea croizatii is known only from the type collection, made in July–October 1951, along the

FIGURE 4. *Persea croizatii.*—A. Habit.—B. Old flowers.—C. Fruit.—D. Inner stamen.—E. Arrangement of anther cells of inner stamen.—F. Outer stamen.—G. Staminode.—H. Pistil.

upper Río Orinoco, probably at low elevation. There are no label data indicating habit, size, habitat, or other information. In Kopp's (1966) revision of the neotropical *Persea* species, *P. croizatii* keys to her section *Eriodaphne* because of its glabrous ovary. It does not seem closely related to any of the species of that section with appressed pubescence, consisting mostly of *P. caerulea* and its relatives, but instead resembles more closely species of section *Aurataea*, especially *P. nivea* Mez and

P. benthamiana Meissner. These species both have, however, whitish and more pubescent lower leaf surfaces and smaller flowers. The inflorescences of *P. benthamiana* are also only half as long as the leaves. In all three species, the inner stamens are longer than the outer ones, which is an unusual feature in *Persea*. Unfortunately, all three species are rarely collected, and I have only seen one collection of each. More collections are needed to elucidate the relationships between these three species, whose distributions are not widely separated from each other.

Persea fluviatilis van der Werff, sp. nov. TYPE: Venezuela. T. F. Amazonas: Depto. Río Negro, inundated forest along lower Río Baria, *G. Davidse 27717* (holotype, MO).

Arbor, ad 10 m. Ramuli crassi, fistulosi, hornotini pubescentes annotini glabri. Folia firme chartacea vel coriacea, elliptica vel anguste elliptica, 15–20 × 3.5–7.5 cm, basi acuta vel obtusa, apice acuta; plus minusve aggregata; nervis lateralibus 8–10, supra immersis, subtus elevatis; margine paulo recurvata. Petioli 2–3 cm longi, juvenales pubescentes, vetustiores glabri. Inflorescentiae axillares, foliis perbreviores, dense pubescentes. Flores viridi-lutei, fere sessiles. Tepala 6, subaequalia, extus dense pubescentia; tepala exteriora late ovata, intus glabra, ad 2.5 mm longa; tepala interiora late ovata, intus pubescentia, ca. 3.2 mm longa. Stamina 6 (series I et II), quadrilocellata, ca. 2.2 mm longa; filamentis pubescentibus, sensim in antheris glabris dilatatis; staminodia serei III ca. 1.9 mm longa, dense pubescentia, ad basim 2 glandulis praedita; staminodia serei IV sagittata, ca. 1 mm longa, dense pubescentia. Ovarium paucis pilis praeditum, ca. 0.8 mm diametro; stylo glabro, gracili, ca. 1.5 mm longo. Fructus globosus; tepala persistentia, patentia; pedicellum at maturitatem fructus incrassatum.

Tree, to 10 m. Twigs stout, terete, hollow, the leaf scars clustered, not evenly distributed along the twigs, older twigs glabrous, recent growth with rather dense, spreading pubescence. Leaves firmly chartaceous or coriaceous, elliptic or narrowly elliptic, 15–20 × 3.5–7.5 cm, apex acute, base acute or obtuse, ± clustered along the twigs; lateral veins 8–10 pairs, immersed on the upper surface, prominently raised on the lower surface, arching towards the tip of the leaf, not connected to the upper lateral vein; margin slightly recurved; upper leaf surface glabrous, lower leaf surface with some erect, gray hairs, these denser along midvein and lateral veins. Petioles 2–3 cm long, gray pubescent when young, glabrous in age. Inflorescences axillary, much shorter than the leaves, to 6 cm long, densely gray pubescent. Flowers greenish yellow or tawny, nearly sessile. Tepals 6, their outside surfaces completely covered by dense, gray pubescence, outer 3 tepals broadly ovate, ca. 2.5 mm long, glabrous inside, inner 3 broadly ovate, ca. 3.2 mm long, pubescent inside. Fertile stamens 6, representing the outer 2 whorls, ca. 2.2 mm long, the filament densely pubescent, ca. 1.2 mm long, gradually widened into and poorly differentiated from the glabrous anther; staminodia of whorl III ca. 1.9 mm long, densely pubescent and with 2 large, globose glands near the base, the tip not cordate or sagittate; staminodia of whorl IV ca. 1 mm long, densely pubescent, sagittate. Ovary with a few hairs, 0.8 mm diam., style glabrous, slender, ca. 1.5 mm long. Fruit globose, ca. 1.3 cm diam., with a glaucous bloom; tepals persisting in fruiting stage, spreading; pedicel in fruit strongly swollen, to 7 mm thick.

Paratypes. VENEZUELA. T. F. AMAZONAS: along Río Temi near Yavita, *Ll. Williams 14122* (F); same locality, *Bunting et al. 4041, 4050* (MY).

Persea fluviatilis is known only from periodically inundated forest in Territorio Federal Amazonas, Venezuela, at elevations of about 100 m. In Kopp's (1966) revision of the neotropical species of *Persea*, it keys to section *Heteranthera* because the stamens of whorl III are sterile. Within that section, it is closest to *P. meridensis*, a poorly known Andean species, which differs in its ferruginous pubescence, pedicelled flowers, and solid twigs. Unusual characters of *P. fluviatilis* are the subequal tepals, hollow twigs, clustered leaves, difference in pubescence between the young and old twigs, and swollen pedicels in fruit. Because many of the neotropical *Persea* species are infrequently collected and are poorly known, close relatives of this distinctive species have not been pinpointed. The swollen pedicels in fruit are a very unusual feature, but because there are only two fruiting collections known, it is possible that this condition is caused by a disease and is not typical for the species. At the time of her revision Kopp had only a fruiting collection of this species at hand, which she cited as *P. nivea* Mez, a species that does not occur in Venezuela.

Rhodostemonodaphne steyermarkiana (Allen) van der Werff, comb. nov. BASIONYM: *Ocotea steyermarkiana* C. K. Allen, Acta Bot. Venez. 2: 216. 1967.

Rhodostemonodaphne, as defined by Rohwer & Kubitzki (1985), includes a small number of species previously included in *Nectandra* or *Ocotea* and differing from *Nectandra* in being dioecious and in a general lack of papillose pubescence on the floral parts; they differ from *Ocotea* in having almost sessile anthers and the locelli ar-

ranged in an arc, not in two superposed rows. A study of the available collections of *O. steyermarkiana* shows that this species has all the characters of *Rhodostemonodaphne*, and therefore a new combination is made. I did not find that the outer stamens have distinct filaments and that the anther cells are arranged in two rows, as Allen described and illustrated. Pubescence and inflorescence type suggest that *R. steyermarkiana* is closely related to *R. celiana* (Allen) Rohwer and *Endlicheria vinotincta* Allen, both endemic to the Venezuelan Guayana. I include two collections from Cerro Sarisariñama, cited by Bernardi in Steyermark (1976) as *O. celiana* Allen and *O. ferruginea* (Meissner) Mez, in *R. steyermarkiana*.

TAXONOMIC STUDIES IN THE MICONIEAE (MELASTOMATACEAE). III. CLADISTIC ANALYSIS OF AXILLARY-FLOWERED TAXA[1]

Walter S. Judd[2]

ABSTRACT

The axillary-flowered members of the Miconieae are hypothesized to be a monophyletic group, and the generic relationships within this group have been investigated by means of a preliminary cladistic analysis, which resulted in the following taxonomic conclusions. *Henriettea* is circumscribed broadly, including *Henriettella* and *Llewelynia*, as is *Loreya*, which is considered to include *Bellucia* and *Myriaspora*. The small genus *Kirkbridea* is likely the sister group of *Henriettea* sensu lato. *Clidemia* sect. *Calophysoides* and *Maieta* form a single clade and are considered congeneric. *Mecranium* (including *Ekmaniocharis*), *Killipia*, *Huilaea*, and the axillary-flowered 5- or 6-merous species of *Ossaea* all are considered generically distinct due to their isolated cladistic positions. Species of *Clidemia* sect. *Sagraea* along with *Necramium* and the axillary-flowered and 4-merous species of *Ossaea* are considered a distinct genus, *Sagraea*; an autapomorphy for this group was not consistently present in the generated cladograms, and the genus is considered metaphyletic. *Clidemia* sect. *Miconiopsis*, although usually considered axillary-flowered, actually has both terminal and axillary inflorescences and may be congeneric with *Miconia* (and likely is related closely to sect. *Tamonea*). Thus, axillary-flowered groups recognized at the generic level include: *Henriettea*, *Huilaea*, *Killipia*, *Kirkbridea*, *Loreya*, *Maieta*, *Mecranium*, *Pentossaea*, and *Sagraea*. Axillary-flowered Miconieae appear to form two major clades based primarily on the crystal type present in the leaf mesophyll and stem. Megastyloids (sometimes along with druses) occur in *Loreya*, *Kirkbridea*, and *Henriettea*, while only druses are found in the remaining genera. Cladistic relationships among the genera possessing only druse crystals are obscure, although *Huilaea* is probably basal within this complex, as reflected by its large flowers with well-developed pedicels, and *Sagraea* is likely most closely related to *Mecranium*, the two being linked by the synapomorphy of 4-merous flowers. Relationships of axillary-flowered taxa to those with terminal infloresences are discussed briefly.

The Miconieae Triana (Melastomataceae) are a diverse tribe of ca. 30 neotropical genera, including ca. 1,800 species. As discussed previously (Judd, 1986a), the genera within the tribe are poorly characterized, often difficult to discern, and defined quite arbitrarily (Cogniaux, 1891; Macbride, 1941; Gleason, 1932, 1958; Wurdack, 1972). In order to clarify relationships within this large and complex group, a preliminary cladistic analysis of the axillary-flowered taxa of Miconieae was conducted as reported here.

Within the Miconieae, the inflorescence may be either terminal or lateral. Plants with terminal inflorescences have hapaxanthic shoots in which the apical meristem of the shoot becomes wholly transformed into a flowering axis after a period of vegetative growth, while plants with axillary inflorescences have pleonanthic shoots in which the apical meristem continues its vegetative activity while producing lateral flowers or inflorescence axes (see Judd, 1986a; Weberling, 1988). Inflorescence position, along with the correlated characters of growth architecture, has been shown to be a valuable taxonomic character in the tribe and is usually uniform within sections or genera (Judd, 1986a).

The axillary-flowered condition is likely a derived state within the Miconieae because nearly all members of the Merianieae show terminal flowers. The latter tribe is a reasonable outgroup taxon considering possible tribal relationships suggested

[1] This research was supported by NSF Grant BSR-8406760. I thank the curators of DUKE, F, GH, NY, MO, and US, from which specimens have been borrowed for this study, and Charles A. Woods, Thomas A. Zanoni, and Lena Green for logistical assistance during fieldwork in Haiti, the Dominican Republic, and Jamaica. I am grateful to James D. Skean, Jr. and Susanne S. Renner for helpful suggestions concerning the manuscript, and to Kathleen A. Kron for assistance with recording specimen data. I also thank Susanne S. Renner for sending me portions of her recent revisions of *Loreya* and *Bellucia*. Thanks are due Kent Perkins for processing specimen loans and to Gerald E. Masters for his fine illustrations.

by J. Wurdack (Welle & Koek-Noorman, 1981). The same conclusion would be reached through the use of a generalized melastomataceous outgroup and the tree counting algorithm of Frolich (1987), since terminal cymose inflorescences are the strongly predominant condition within non-Miconieae melastomes. Terminal inflorescences occur in over 80% of non-Miconieae genera, and strongly predominate in all tribes except the Blakeeae Benth. & Hook. f. In addition, Weberling (1988) noted that all melastomes show monotelic inflorescences, with the basic form being a pleiothyrsoid terminating a leafy shoot. In this study the monophyly of the axillary-flowered Miconieae was accepted as a useful preliminary hypothesis and a cladistic analysis of these taxa was conducted. The results of this analysis are then used to suggest generic realignments and to reevaluate the preliminary hypothesis of monophyly of the axillary-flowered taxa.

Cladistic Analyses

METHODS

The cladistic analyses were conducted using the Wagner parsimony algorithm (with global branch-swapping and multiple parsimony options) of the PAUP (i.e., Phylogenetic Analysis Using Parsimony, Version 2.4; Swofford, 1985) package of computer software.

Fifteen Evolutionary Units (EUs) were used in most of the analyses (Table 1), based on a survey of ca. 370 herbarium specimens representing 150 species (and supplemented, where possible, by the addition of information from recent taxonomic studies). Several taxa also were studied during the course of fieldwork in Haiti, the Dominican Republic, Puerto Rico, and Jamaica. In some analyses, an additional EU representing either a generalized terminal-flowered taxon or *Clidemia* sect. *Miconiopsis* Cogn. was used. Although terminal-flowered, *Clidemia* sect. *Miconiopsis* has been considered to be related to the other sections of *Clidemia* included in this study, and its inclusion in a few analyses was designed to test this hypothesis. The inclusion of a generalized terminal-flowered taxon in some analyses was designed, in a very preliminary way, to evaluate the hypothesis that the axillary-flowered Miconieae are monophyletic. Placement of this generalized terminal-flowered taxon is considered very tentative because this EU is extremely heterogeneous, making the determination of its ancestral character states problematic (see Table 1).

Forty-two characters were used and assigned plesiomorphic (ancestral: scored as 0) and apomorphic (derived: scored as 1) states (Table 1). Apomorphic features used in the computer analyses are listed below. Nearly all characters were polarized using the Merianieae as an outgroup, with character states uniformly found (or, for a few characters, those states most commonly represented) in the out-group considered plesiomorphic (Stevens, 1980; Wheeler, 1981; Wiley, 1981; Maddison et al., 1984; Frolich, 1987). When EUs are polymorphic for a given character, an estimate of the ancestral condition was made. The states of a few characters were unknown for certain taxa, and these are scored as "missing data," indicated by a "?" in the data matrix (Table 1). Trees were rooted by using a hypothetical ancestor with all characters scored as plesiomorphic.

APOMORPHIC CHARACTERS

1. Stems quandrangular and 4-winged/ridged; plesiomorphic condition: stems ± terete. Quadrangular stems are considered an autapomorphy of *Killipia* Gleason and occur in *K. quadrangularis* Gleason (the type species). However, two other species have terete stems, and the ancestral condition within *Killipia* is not known. A coding of "0" for this EU would not affect the analyses because the feature is autapomorphic.

2. Growth pleonanthic (indeterminate); plesiomorphic condition: growth hapaxanthic (determinate). (See character 12.)

3. Megastyloid crystals present; plesiomorphic condition: only small styloids and/or druse crystals present. (See character 4.)

4. Crystals exclusively druses; plesiomorphic condition: small or large styloids and druse crystals present. The polarity of characters 3 and 4 was determined by using the Crypteroniaceae (Dahlgren & Thorne, 1984) as an outgroup (see discussion in Johnson & Briggs, 1984; Vliet et al., 1981). This family, which is closely related to the Melastomataceae, contains genera with druses and with small styloids (Baas, 1981), and this crystal complement is taken as the ancestral condition in melastomes. It is likely that megastyloids have evolved in a few lineages (sometimes with the loss of druses), while styloids have been lost in other lineages, resulting in druses being the only crystal type in those groups. That styloids and druses are known from more distantly related families of Myrtales, such as Myrtaceae and Combretaceae (Vliet & Baas, 1984) supports this polarity. Variation in crystal complement within the Merianieae is poorly known.

5. Elongate multicellular hairs absent; plesio-

TABLE 1. Character divergence values for taxa used in cladistic analyses. Taxon names abbreviated by first four letters of genus name, except *Henriettea* (HENT), *Henriettella* (HENL), *Clidemia juruensis* (CJUR), generalized terminal-flowered taxon (TERM). An asterisk indicates that the opposite state occurs in some species of that taxon; a question mark indicates that the character state is in doubt or unknown.

morphic condition: elongate multicellular hairs present, often strigose. *Mecranium* Hook. f. and *Killipia* are unique in lacking a well-developed indumentum. A few species of *Loreya* DC., e.g., *L. ovata* Berg ex Triana, *L. arborescens* (Aublet) DC., and *L. nigricans* Triana, lack such hairs as well. Renner (in press) hypothesized the loss of strigose hairs to be a synapomorphy of a species group within *Loreya*. Thus, the presence of such hairs is considered the ancestral condition within the genus.

6. Multicellular hairs elongate with radiate to stellate-globular basal portion (or clearly derived types); plesiomorphic condition: multicellular hairs various, but not as above. This distinctive hair morphology is much modified (see discussion, and Judd, 1986b) in a few species, but such extremes are connected by intermediate types, sometimes even on the same plant.

7. Multicellular hairs minute, globular, and unbranched to irregularly branched and matted (not strigose); plesiomorphic condition: multicellular hairs various but not as above. This character is limited to *Mecranium* (including *Ekmaniocharis* Urban) and *Ossaea acuminata* DC. The feature is important in determining that *Mecranium* spp., *Ossaea acuminata*, and *Ekmaniocharis crassinervis* Urban form a monophyletic group but does not help in inferring relationships among the EUs.

8. Multicellular hairs conspicuously stellate (with stalk and elongated arms); plesiomorphic condition: multicellular hairs various but not as above. In these analyses this feature is considered an autapomorphy of *Clidemia* sect. *Miconiopsis*. Very similar hairs occur in many terminal-flowered species, e.g., *Miconia* sects. *Jucunda* (Cham.) Naudin and *Tamonea* (Aublet) Cogn.

9. Leaves clearly anisophyllous; plesiomorphic condition: leaves isophyllous or nearly so. A few specialized species of *Clidemia* sect. *Sagraea* (DC.) Cogn. have anisophyllous leaves. The isophyllous condition is considered ancestral within *Clidemia* sect. *Sagraea*, following a preliminary analysis of variation within the group.

10. Leaves with pair of pouchlike formicaria at base of blade; plesiomorphic condition: leaves lacking formicaria. Similar ant-domatia that occur in terminal-flowered taxa, e.g., *Tococa* Aublet, *Clidemia* D. Don, *Myrmidone* Mart., probably evolved independently (see discussion). *Ossaea bullata* (Pilger) Gleason, possibly a member of the *Sagraea* group, has been reported to possess similar formicaria (Whiffin, 1972).

11. Cuticle of abaxial leaf epidermis papillose; plesiomorphic condition: epidermis nonpapillose. Renner (in press) pointed out that this feature correlates well with cuticle thickness and suggested that the character has important ecological consequences.

12. Inflorescences axillary (in leaf axils or at nodes on old wood); plesiomorphic condition: inflorescences terminal. Terminal cymose inflorescences (as discussed above) occur in over 80% of genera within non-Miconieae melastomes. Thus, proliferating inflorescences (in which the terminal axis returns to vegetative growth, producing axillary buds that develop vegetative branches instead of flower-bearing paracladia—see Weberling, 1988) are considered derived. The process of proliferation results in a vegetative shoot in which the flowers are borne in axillary cymose paracladia. Delayed anthesis of the paracladia can even result in cauliflory.

13. Inflorescences fasciculate; plesiomorphic condition: inflorescences cymose. Although fascicles occur in a few species of *Loreya*, *Clidemia* sect. *Sagraea* (including axillary, 4-merous species of *Ossaea* DC.), and the 5-(6-)merous species of *Ossaea*, cymose inflorescences are considered to be the ancestral condition in these groups. Renner (in press) also considered fasciculate inflorescences to be derived within *Loreya*.

14. Flowers more or less sessile; plesiomorphic condition: flowers pedicellate.

15. Flowers 4-merous; plesiomorphic condition: flowers other than 4-merous. (See character 16.)

16. Flower parts frequently more than 5; plesiomorphic condition: flowers 4- or 5-merous. Generally, 5-merous flowers are considered primitive, with higher and lower floral numbers treated as derived. *Henriettea* DC. and *Loreya* contain a few species with numerical plans greater than five, while *Henriettella* Naudin and *Kirkbridea* Wurdack contain a few species with 4-merous flowers. Within each of these genera, 5-merous flowers are considered ancestral. Renner (in press) considered floral numbers greater than five to be derived and used this feature to link some species of *Loreya* with *Bellucia* Raf. The ancestral condition in *Kirkbridea* is in doubt; however, recoding the state of this EU as "1" for this character does not change the topology of the discovered cladograms.

17. Flowers small; plesiomorphic condition: flowers moderate to large.

18. Hypanthium strongly ribbed; plesiomorphic condition: hypanthium nonribbed. This character is an autapomorphy of *Clidemia* sect. *Calophysoides* Cogn.

19. External calyx lobes more or less conspicuous and well developed; plesiomorphic condition: external calyx lobes absent or inconspicuous.

20. External calyx lobes absent; plesiomorphic

condition: external calyx lobes present. Some species of *Henriettella* have lost external calyx lobes independently of the loss in *Loreya*, *Bellucia*, and *Myriaspora* DC. This was determined because it is evident that *Henriettella* evolved out of a group within *Henriettea*, which has external calyx lobes.

21. Internal calyx lobes very elongate and closely associated with external lobes; plesiomorphic condition: internal calyx lobes not elongate, variously developed but not closely appressed to internal lobes. This feature is an autapomorphy of *Killipia*.

22. Internal calyx lobes connate into a membranous, dome-shaped, apiculate cap that ruptures irregularly at anthesis; plesiomorphic condition: internal calyx lobes free. This character is an autapomorphy of *Mecranium* (including *Ekmaniocharis*). Although *Ossaea acuminata* has somewhat caplike calyx lobes, they are only partially connate. The internal calyx lobes are free and imbricate at their extreme apices. This species is included within the *Mecranium* EU since it has the other apomorphies of this clade (characters 7, 19, and 32; see discussion).

23. Internal calyx lobes circumscissilly dehiscent (and noncalyptrate); plesiomorphic condition: internal calyx lobes more or less persistent, or if circumscissile, then calyptrate. This character is considered an autapomorphy of *Clidemia* sect. *Miconiopsis*, although a similar condition is seen in *Miconia* sects. *Tamonea* and *Jucunda* (a group included within the generalized terminal-flowered taxon).

24. Buds closed, with thick triangular calyx lobes that cover bud up to the final stage prior to anthesis (and sometimes fused into a cap); plesiomorphic condition: buds open, calyx lobes of variable shape and thin, the petals exposed much before anthesis. This feature is an autapomorphy of *Bellucia*.

25. Internal calyx lobes reduced to a more or less smooth rim; plesiomorphic condition: internal calyx lobes clearly evident. This is a noninformative character (see Table 1) because it is found only in a few derived species within *Henriettella* and *Clidemia* sect. *Sagraea*.

26. Internal calyx lobes fused into a conical, apically closed calyptra and conspicuously strigose; plesiomorphic condition: internal calyx lobes noncalyptrate (or if so, then not as above). This is an autapomorphy of *Myriaspora*.

27. Internal calyx lobes fused into an apically open cap (opening into sepal-like segments or circumscissilly); plesiomorphic condition: internal calyx lobes noncalyptrate (or if so, then not as above). This feature is limited to *Llewelynia* Pittier and a few (probably related) species of *Henriettea* (see discussion).

28. Calyx a cap open at apex and falling off by circumscissile slit; plesiomorphic condition: calyx not open-calyptrate, or if so, then opening by longitudinal slits into triangular sepal-like segments. This character is an autapomorphy of *Llewelynia* and is a further specialization of character 27.

29. Petals narrowly triangular and more or less acute at apex; plesiomorphic condition: petals ovate to elliptic (or obovate) with blunt to more or less acuminate apices. Preliminary analyses of variation within *Mecranium* (including *Ekmaniocharis*) and *Clidemia* sect. *Sagraea* (including axillary, 4-merous species of *Ossaea*) have led to the conclusion that ovate to elliptic petals with more or less acuminate to blunt apices constitute the ancestral condition within these groups. Obovate petals have evolved within a group of *Mecranium* species. It is noteworthy that *Ossaea acuminata*, a narrow-petaled species, is a sister species to *Mecranium amygdalinum* (Desr.) C. Wright in Sauv., a fairly blunt-petaled species (Skean, in prep.).

30. Petals with a dorso-apical tooth; plesiomorphic condition: petals lacking a dorso-apical tooth. This feature occurs in a few species of *Clidemia* sect. *Sagraea* (including the species of *Ossaea* with axillary, 4-merous flowers) and in the 5- or 6-merous species of *Ossaea*. A scoring of "1" for this character in these two EUs does not alter their placement in relation to the very different *Henriettea* group.

31. Petals usually pubescent, sometimes only with very few hairs near apex; plesiomorphic condition: petals glabrous (or with a single apical hair). Hairs on the petals have been lost in a few species of *Loreya* and *Bellucia*.

32. Androecial fringe present; plesiomorphic condition: androecial fringe absent. This feature is a strong and consistent synapomorphy of *Mecranium* species, including *Ekmaniocharis crassinervis* and *Ossaea acuminata*.

33. Anthers with two well-developed dorso-basal projections; plesiomorphic condition: anthers various but lacking two well-developed dorso-basal projections.

34. Anthers usually robust and fleshy, opening by one or two minute pores; plesiomorphic condition: anthers not robust and fleshy, various.

35. Anther sacs basally bifurcate, i.e., sagittate; plesiomorphic condition: anther sacs not bifurcate at base.

36. Anther sacs more or less wrinkled; plesiomorphic condition: anther sacs smooth. The best expression of this feature is in *Maieta* Aublet.

37. Stamens numerous, i.e., more than twice

the number of petals; plesiomorphic condition: stamens twice the number of petals. This is an autapomorphic character of *Llewelynia*.

38. Stigma very conspicuously and radiately ridged; plesiomorphic condition: stigma not radiately ridged.

39. Placenta highly divided; plesiomorphic condition: placenta undivided or nearly so. This is an autapomorphy of *Myriaspora*.

40. Fruit a berry; plesiomorphic condition: fruit a capsule.

41. Chromosome number of $n = 28$; plesiomorphic condition: $n = 17$ (or 15, 20). (See character 42.)

42. Chromosome number of $n = 15, 20$; plesiomorphic condition: $n = 17$ (or 28). The terminal-flowered Miconieae were used as a generalized outgroup for the determination of polarity of the incompletely known characters 41 and 42.

RESULTS

Initial computer runs using the entire data set for the 15 axillary-flowered EUs resulted in the discovery of 100+ equally parsimonious trees (but only 15 different topologies when multi-furcations are taken into account), all with a length of 28 steps and a consistency index of 0.714 (or 48 steps and consistency index of 0.813 when autapomorphies and uniform characters were included). The strict consensus tree resulting from this analysis is presented in Figure 1B. In addition a tree indicating character state changes is presented (Fig. 1A). This tree is preferred due to its pattern of character variation, especially the linking of *Mecranium* and *Clidemia* sect. *Sagraea* on the basis of 4-merous flowers (15), and the linking of *Henriettea*, *Henriettella*, and *Llewelynia* on the basis of fasciculate inflorescences (13). The relationships of the EUs representing *Loreya*, *Bellucia*, *Myriaspora*, *Henriettea*, *Henriettella*, and *Llewelynia* did not vary in any of the trees generated by PAUP. In addition, *Kirkbridea* consistently linked with *Henriettea*, *Henriettella*, and *Llewelynia*, in some trees as the cladistically basal member of this clade, in others as the sister group of *Henriettella*. In all trees, the EUs representing *Maieta*, *Clidemia* sect. *Calophysoides*, and *Clidemia juruensis* (Pilger) Gleason were always joined, and *Huilaea* Wurdack was always the basal member of the clade representing taxa with only druse crystals. Thus the large number of generated trees is due to the numerous possible topologies among the remaining EUs in the analyses, i.e., *Mecranium* (including *Ekmaniocharis* and *Ossaea acuminata*), *Clidemia* sect. *Sagraea* (including *Necramium* Britton and axillary 4-merous species of *Ossaea*), *Killipia*, and *Pentossaea*, here described to include the axillary-flowered, 5-merous (or less commonly 6-merous) species of *Ossaea*.

Thus, several analyses were conducted using just those EUs possessing only druse crystals (i.e., top eight EUs listed in Table 1) with characters not pertaining to this complex deleted. These analyses generated 45 equally parsimonious trees (but comprising only seven different tree topologies) of 11 steps and with a consistency index of 0.727 when all characters were weighted equally (or of 25 steps and a consistency index of 0.880 when autapomorphies and uniform characters were included). However, when the apomorphy of 4-merous flowers was stressed (weighted by 2, as seems reasonable, since this character is quite uniform within EUs under investigation), only 15 trees (representing only two topologies) were produced, all with 12 steps and a consistency index of 0.750 (or of 26 steps and a consistency index of 0.889 when autapomorphies and uniform characters were included). The consensus tree resulting from the analysis in which all characters are weighted equally is identical to that produced in the analysis of all axillary-flowered taxa (Fig. 1B). Both cladograms resulting from the weighted-character analysis are given in Figure 1C and D.

When an EU representing a generalized terminal-flowered taxon is included in the analysis, over 100 equally parsimonious trees were found, all with a length of 32 steps and a consistency index of 0.688 (or of 50 steps and a consistency index of 0.780 when autapomorphies and uniform characters were included). These trees are very similar to those generated in the analyses involving only axillary-flowered taxa (Fig. 1), and the four different topologies involving their basal branches are presented in Figure 2, illustrating the various positions of the genus *Huilaea* and a generalized terminal-flowered taxon. When *Clidemia* sect. *Miconiopsis* (another taxon producing terminal inflorescences) is included in the analysis, many trees are again generated (of 55 steps and a consistency index of 0.745, including autapomorphies), all linking this entity with either *Killipia* or a clade containing *Killipia*, *Clidemia* sect. *Sagraea*, and *Mecranium*.

DISCUSSION

The cladograms presented in Figures 1 and 2 indicate that the axillary-flowered Miconieae are divided into two major clades. The first is composed of those taxa containing megastyloids (3) in their leaf and stem tissues (often with druse crystals as well) and usually possessing slightly pubescent petals (31). The group also generally has distinctly

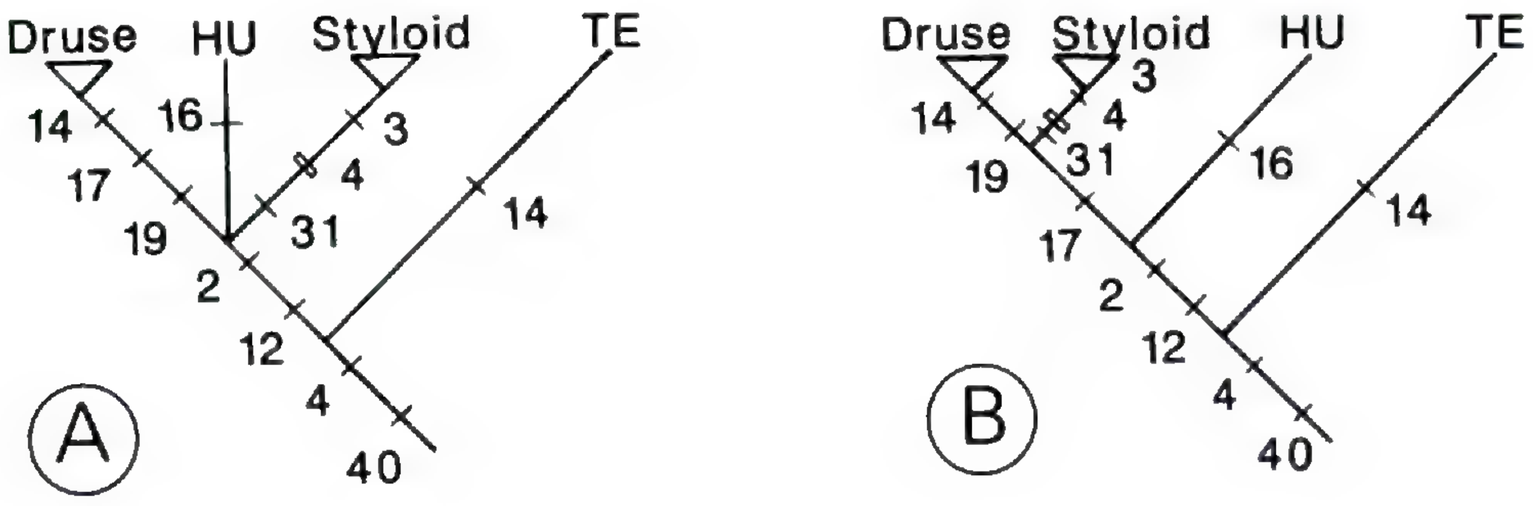

FIGURE 2. Basal portion of cladograms resulting from analysis of axillary-flowered taxa and generalized terminal-flowered taxon, all of 50 steps, consistency index = 0.78. Reversals indicated by open bars. Taxon abbreviations: *Huilaea* (HU), exclusively druse-containing group (Druse), megastyloid-containing group (Styloid), and generalized terminal-flowered taxon (TE). *These characters could also have evolved independently in basal members of megastyloid- and druse-containing lineages (see text).

pedicellate flowers. This clade may be divided into two clearly marked subgroups based on vegetative and reproductive characters. *Loreya*, *Bellucia*, and *Myriaspora* are united by the synapomorphies of flowers lacking external calyx lobes (20), possessing robust fleshy anthers (34), an expanded and radiately ridged stigma (38), and a chromosome number of $n = 15$ or 20 (42). In contrast, *Henriettea*, *Henriettella*, *Llewelynia*, and *Kirkbridea* form a clade based upon the presence of multicellular strigose hairs with a stellate, radiate, irregularly branched, or suprabasally expanded base, or hair types clearly modified from these conditions (6), petals with an apical apiculum on the abaxial surface (30), and a chromosome number of $n = 28$ (where known, 41). *Kirkbridea* likely is cladistically basal in this group, with *Henriettea*, *Henriettella*, and *Llewelynia* being united by the additional synapomorphy of fasciculate inflorescences (13). (It should be noted that parallelism in flower size (17) occurs within these genera, which is not surprising considering the variability of this feature within the tribe. Linking *Kirkbridea* and *Henriettella* on the basis of this character is considered implausible.)

The remaining taxa included in the analysis form a second clade based on the following synapomorphies: presence of only druse crystals in leaf and stem tissues (4), small more or less sessile flowers (17, 14), and usually well-developed external calyx lobes (19). The extremely isolated genus *Huilaea* probably is basal within this clade (Fig. 1A, B) because it shows only the synapomorphy of exclusive presence of druse crystals (4), having large and clearly pedicellate flowers. The relationships among the taxa comprising this clade are not well resolved. However, it is clear that *Maieta*, *Clidemia* sect. *Calophysoides*, and *C. juruensis* form

FIGURE 1. Cladograms resulting from PAUP analyses.—A. Preferred tree resulting from analysis of all axillary-flowered taxa, 48 steps, consistency index = 0.813.—B. Consensus tree.—C, D. Cladograms resulting from PAUP analyses of taxa containing only druse crystals—two 26-step trees generated in analysis weighting character 15; topology C equals consensus tree of this analysis. Reversals indicated by open bars; taxa abbreviated by first two letters of generic or sectional name, except *Henriettea* (HT), *Henriettella* (HL), and *Kirkbridea* (KK).

a monophyletic group based on the presence of morphologically very similar pouchlike ant-domatia (formicaria) at the base of the leaf blade (10) and wrinkled anthers (36). In addition, *Maieta* and *Clidemia* sect. *Calophysoides* have anisophyllous leaves (9). If the character of 4-merous flowers is stressed, then *Mecranium* is probably most closely related to *Clidemia* sect. *Sagraea*, and the two may be linked by this feature (15). Linking *Killipia* with *Sagraea* and *Mecranium* in some trees on the basis of the shared loss of strigose hairs (5) probably has little phylogenetic significance.

The terminal-flowered taxa of Miconieae may be a paraphyletic or monophyletic group basal to all the axillary-flowered taxa (Fig. 2A–C) or a possible sister taxon to the taxa containing only druses (Fig. 2D). In the first alternative, the axillary-flowered condition evolved just once and serves as a synapomorphy of all axillary-flowered Miconieae; in the second, axillary arrangements are hypothesized to have evolved in the druse and megastyloid clades independently (or, less likely, evolved in the stem lineage of the entire tribe with a reversal to terminal cymes occurring in the ancestor of *Miconia* and relatives). The possible polyphyly of the axillary-flowered Miconieae clade will be investigated more thoroughly in a later paper. It is certainly possible that *Miconia* and relatives are more closely related to the axillary-flowered "druse-containing" genera than initially hypothesized.

When an EU representing a generalized terminal-flowered taxon is included in the analysis, the position of *Huilaea* in the cladograms becomes more variable than in the initial analyses (compare Figs. 1 and 2). This variability may reflect the presumed phylogenetic isolation of this genus. It seems more reasonable to link *Huilaea* with *Mecranium*, *Clidemia* sect. *Sagraea*, *Maieta*, and *Killipia* on the basis of the presence of only druse crystals in its tissues (4) than with *Loreya*, *Henriettea*, and *Kirkbridea* on the basis of a reversal to pedicellate flowers (14) (Fig. 2).

The presence of both terminal and axillary flowers in *Clidemia* sect. *Miconiopsis* (Cogniaux, 1888, 1891) is not surprising (see Judd, 1986a, for discussion of similar variation evident in *Miconia*, especially in sects. *Octomeris* (Naudin) Benth. & Hook. and *Tamonea*; and Troll, 1964, and Weberling, 1965, 1988, for more general discussion of inflorescence structure and position). Wurdack's suggestion (pers. comm.) that this group is closest to *Miconia* is likely correct. Note especially the similarity in stellate indumentum (8; Fig. 4) and circumscissilly dehiscent calyx (23). The section may be quite close to *Miconia* sects. *Tamonea* and *Jucunda*. The linking of *Clidemia* sect. *Miconiopsis* with *Killipia* or a clade containing *Killipia*, *Clidemia* sect. *Sagraea*, and *Miconia* in the cladistic analysis probably is due to homoplasy in several fairly weak characters, e.g., loss of strigose hairs (5), or to several potential synapomorphies between the axillary-flowered taxa containing only druse crystals and *Miconia* (and relatives), e.g., more or less sessile flowers (14) or well-developed external calyx lobes (19).

In spite of the necessarily preliminary nature of these cladistic analyses, their results help determine the previously confused generic limits within this difficult tribe (see also Judd, 1986a, b). In interpreting these results, I have attempted to delimit monophyletic and phylogenetically equivalent genera within the tribe that are recognizable on the basis of several morphological characters. Thus *Huilaea*, *Mecranium* (including *Ekmaniocharis* and *Ossaea acuminata*), *Killipia*, *Maieta* (including *Clidemia* sect. *Calophysoides* and *C. juruensis*), *Loreya* (including *Bellucia* and *Myriaspora*), *Henriettea* (including *Henriettella* and *Llewelynia*), and *Kirkbridea* are considered to be generically distinct. In addition, *Clidemia* sect. *Sagraea* (including *Necramium* and the species of *Ossaea* with axillary 4-merous flowers) is recognized at the generic level. Finally, the species of *Ossaea* with axillary 5- (or 6-)merous flowers are in need of generic recognition and are described herein as *Pentossaea*. The systematics of each of these taxa is discussed briefly below.

Discussion of axillary-flowered genera. *Loreya* is clearly delimited by its distinctive usually robust fleshy anthers (34), expanded and radiately ridged stigma (38), lack of external calyx lobes (20), and range of chromosome numbers (42, see Solt & Wurdack, 1980). The group possesses megastyloids in its leaf and stem tissues (pers. obs.; Baas, 1981) and is clearly monophyletic. However, if *Bellucia* and *Myriaspora* are segregated as separate genera, the result is a paraphyletic *Loreya* (Fig. 1). *Bellucia* is characterized by papillose abaxial leaf cuticle (11), closed buds (24), i.e., the buds have thick calyx lobes that cover the buds up to the final stage prior to anthesis (and are even fused into a cap in a few species, e.g., *Bellucia dichotoma* Cogn. and *B. acutata* Pilger), and tendency for floral merosities greater than five (16) (see Renner, in press). In contrast, *Myriaspora* is characterized by its highly divided placentae (39), calyx lobes fused into an unusual cap (26, which is probably not homologous with the cap of some species of *Bellucia*), and long hairs on the abaxial

surface of its petals. In addition, *Myriaspora* produces inflorescences in the leaf axils (as do several species of *Bellucia*), while the usual condition in *Loreya* is to have the inflorescences lateral on leafless nodes below the leaves; it should be noted, however, that this character is often variable within a genus (Judd, 1986a; Renner, in press).

No autapomorphies are evident for *Loreya* when certain species are segregated as either *Bellucia* or *Myriaspora* (Fig. 1). The paraphyly of *Loreya* is made even more apparent when it is realized that *Loreya subrotundifolia* (Wurdack) S. Renner and *L. riparia* S. Renner link with *Bellucia* on the basis of higher numbers of floral parts and that *L. mespiloides* Miq., *L. spruceana* Benth. ex Triana, and *L. klugii* S. Renner link with *Myriaspora* on the basis of testa characters and one-pored anthers (Renner, in press).

Thus, recognition of *Bellucia* and *Myriaspora* distorts the best estimate of phylogenetic structure currently available for this group of species. Their recognition is also doubtful on purely phenetic grounds, since the patristic distances separating *Bellucia* and *Myriaspora* from the cladistically related taxa within a narrowly delimited *Loreya* are comparable to those separating other clades within *Loreya* (Renner, in press). Thus, as is characteristic of traditional taxonomic procedure (see Stevens, 1984, 1986), recognition of *Bellucia* and *Myriaspora* can only be justified by selective weighting of certain features (in this case the characters of cuticular papillae, bud structure, placental form, and inflorescence position) due to their supposed greater ecological significance. I see no reason to weight these characters more than any others used in these analyses. The decision to recognize a broadly circumscribed *Loreya* is not new; Baillon (1877) also considered *Bellucia* and *Loreya* congeneric (although only few species were known to him), and Macbride (1941: 497) considered this treatment "preferable it seems . . . to 'straining at a gnat' to keep them apart." Gleason (1932) considered the genera only "weakly separated"; however, they were maintained as distinct by Wurdack (1973, 1980) and Renner (in press).

Henriettea is easily recognized by its usually fasciculate inflorescences (13), distinctive indumentum of elongate multicellular hairs with an expanded, radiate to globular-stellate basal portion (or easily derived types, such as stellate-hairs, peltate-scales, elongate hairs with numerous small mainly basal projections, elongate hairs with a suprabasal expanded region and a narrowed basal attachment, or hairs very reduced, e.g., *Henriettella caudata* (DC.) Naudin, *H. glabra* Cogn.; see Wurdack, 1986) (6), petals with a minute dorsoapical apiculum (30), and chromosome number of $n = 28$ (41, Solt & Wurdack, 1980). Fasciculate inflorescences have evolved independently in a few species of *Loreya* (Renner, in press), and the inflorescences of *Henriettea squamulosa* (Cogn.) W. Judd have reverted to a pedunculate condition (Judd, 1986b). *Henriettea* is clearly monophyletic and shows the presence of calcium oxalate megastyloids (similar in structure to those of *Loreya*) in its leaf and stem tissues (pers. obs.; see also Welle & Mennega, 1977; Welle & Koek-Noorman, 1981; Baas, 1981).

As with *Loreya*, problems of paraphyly occur when *Llewelynia* and *Henriettella* are recognized as distinct from *Henriettea* (Fig. 1). *Llewelynia* is phenetically distinctive (Pittier, 1939; Wurdack, 1973) and easily recognized by its loss of external calyx lobes (20), open calyx cap that opens by a circumscissile slit (27, 28), and numerous stamens (37), while *Henriettella* is only marginally separable due to its smaller flowers (17) and tendency to have shorter anthers that open by larger, gaping pores (see Wurdack, 1973, 1980). A nearly obsolete internal calyx has evolved in a few species of *Henriettella*, e.g., *H. sessilifolia* (L.) Triana, and in many species the internal calyx lobes are not well developed. *Henriettea* and *Henriettella* were considered congeneric by Macbride (1941: 500), who stated that "there seems to be no significant concomitance of the characters of petals, anthers or pubescence that have been used to maintain two similar but distinct genera." He added that "the characters moreover often exist in degrees of development." Richard A. Howard also will consider *Henriettea* and *Henriettella* to be congeneric in his Lesser Antilles flora (pers. comm.). Wurdack (1972: 418) maintained these genera but noted that "a generic transition zone exists between *Henriettella ovata* Cogn. and *Henriettea patrisiana* DC., with *Henriettella parviflora* (Griseb.) Triana perhaps not distinct from the latter."

The genera differ in flower size, anther characters, and indumentum, but intermediates exist. Not surprisingly, there are no autapomorphies for *Henriettea* when defined narrowly, and its species certainly intergrade with *Henriettella*.

The floral buds of some other species of *Henriettea* (e.g., *H. spruceana* Cogn., *H. succosa* (Aublet) DC., *H. stellaris* Berg ex Triana, and *H. ramiflora* (Sw.) DC.) possess an expanded and open cap formed by the inner calyx lobes very similar to (and likely homologous with) that of *Llewelynia*, although opening longitudinally rather than cir-

cumscissilly. These species are likely basal members of the clade leading to *Llewelynia*. It is of interest that Wurdack (1973) suggested a similarity in general facies between *Llewelynia* and *Henriettella*, and Welle & Koek-Noorman (1981) reported similarity in wood anatomical characters between *Llewelynia* and *Henriettella*. It thus seems best to recognize a broadly defined, and monophyletic *Henriettea* by including both *Henriettella* and *Llewelynia* within it.

Kirkbridea clearly is related closely to *Henriettea* s.l. (Fig. 1). *Kirkbridea* (Wurdack, 1976) is quite distinctive due to its pedunculate inflorescences and anthers with two well-developed dorsobasal projections (33). *Kirkbridea* and *Henriettea* show variation in number of floral parts.

Huilaea is evidently very isolated, as Wurdack (1957, 1976) suggested at the time of his description of the genus. It clearly is distinct generically and is recognizable due to its pendent, three-flowered cymose inflorescences with very long peduncles and large, clearly pedicellate, 6-merous flowers.

Maieta, defined broadly, is a monophyletic group best recognized by its characteristic pouchlike formicaria at the base of its leaf blades (10) (Fig. 3; see discussion of morphology, development, and ecological functions of these structures in Gleason, 1931; Schnell, 1967; Whiffin, 1972; Neto & Asakawa, 1978; Benson, 1985). It should be noted that ant-domatia of various types undoubtedly have evolved independently in a few to many species of several other genera (e.g., *Sagraea* DC., *Tococa*, *Clidemia*, *Henriettea*, and *Conostegia* D. Don), and additional developmental studies are necessary in order to determine appropriate homologies of such structures within the tribe. The presence of structurally and positionally very similar pouchlike ant-domatia is accepted as a provisional synapomorphy of *Maieta* s. str. and *Clidemia* sect. *Calophysoides* until such developmental investigations are conducted. The group also tends to have slightly wrinkled anthers (36) and clearly anisophyllous leaves (9). Druses are the only crystals known in this group. The species of *Maieta* (defined narrowly—see Aublet, 1775; Wurdack, 1980) have sagittate anthers (35) and show a reversal toward large flowers (17), while those of *Clidemia* sect. *Calophysoides* have a distinctly ribbed hypanthium (18). Both, along with possibly a few other species of *Clidemia*, such as *C. juruensis*, are considered congeneric. The close relationship between these species of *Clidemia* with pouchlike formicaria and the phenetically similar species of *Maieta* has long been recognized. Macbride (1941: 479) remarked that "*Clidemia* remains . . . a concept rather arbitrarily retained but conveniently so on account of *Maieta* (in which Baillon, Hist. Pl. 7: 56. 1880 rightly merged it) being the older name." I agree and here consider *Maieta* to be congeneric with *Clidemia* sect. *Calophysoides* (and *C. juruensis*).

Killipia (Fig. 4) is a distinctive genus not easily confused with any other in the complex of genera possessing only druse crystals. Noteworthy apomorphies are the very long internal calyx lobes with closely associated external calyx lobes (21) and distinctive anthers with two dorso-basal projections (33); see description of genus in Gleason (1925). The stems of *Killipia quadrangularis* are quadrangular and ridged-winged (1); however, two other species have terete stems. The abaxial leaf surface of *K. quadrangularis* is usually red, an apomorphy not included in the analysis, which has also evolved within several genera with terminal inflorescences. The cladistic relationships of *Killipia* are obscure, although it is closest to *Maieta*, *Mecranium*, *Sagraea*, and *Pentossaea* (Fig. 1).

The species formerly of *Ossaea* with axillary 5-merous or occasionally 6-merous flowers warrant generic recognition (Fig. 5). The petals of this group are narrowly triangular with an acute apex (29), and the group is clearly separable from related taxa (see key). It is not surprising that a group of *Ossaea* species was found to be in need of generic recognition, since the genus has long been suspected of being polyphyletic (see Judd, 1986a). Wurdack (1962: 206), for example, stated that "the genus is an artificial assemblage of various species groups." The distinctive clade, with axillary 5-(6-)merous flowers, is here described as the genus *Pentossaea*.

Pentossaea W. Judd, gen. nov.

Genus novum, *Sagraea* DC. affine, a quo floribus 5-meris (vs. 4-meris), petalis semper anguste triangularibus, apicibus acutis differt. TYPE SPECIES: *Pentossaea brachystachya* (DC.) W. Judd.

Evergreen subshrubs or shrubs with pleonanthic shoots; twigs ± terete, nodose, glabrous to densely strigose, with a ridge encircling each node; druse crystals present. Indumentum of conspicuous, unbranched, slender to stout, strigose, multicellular hairs with or without glandular apices and of minute, multicellular, glandular hairs (or sometimes glandular-stellate hairs) occurring on stems, leaves, inflorescence axes, and hypanthia, or in some species ± restricted to reproductive parts. Buds narrowly ovoid, sylleptic, usually densely pubescent. Leaves

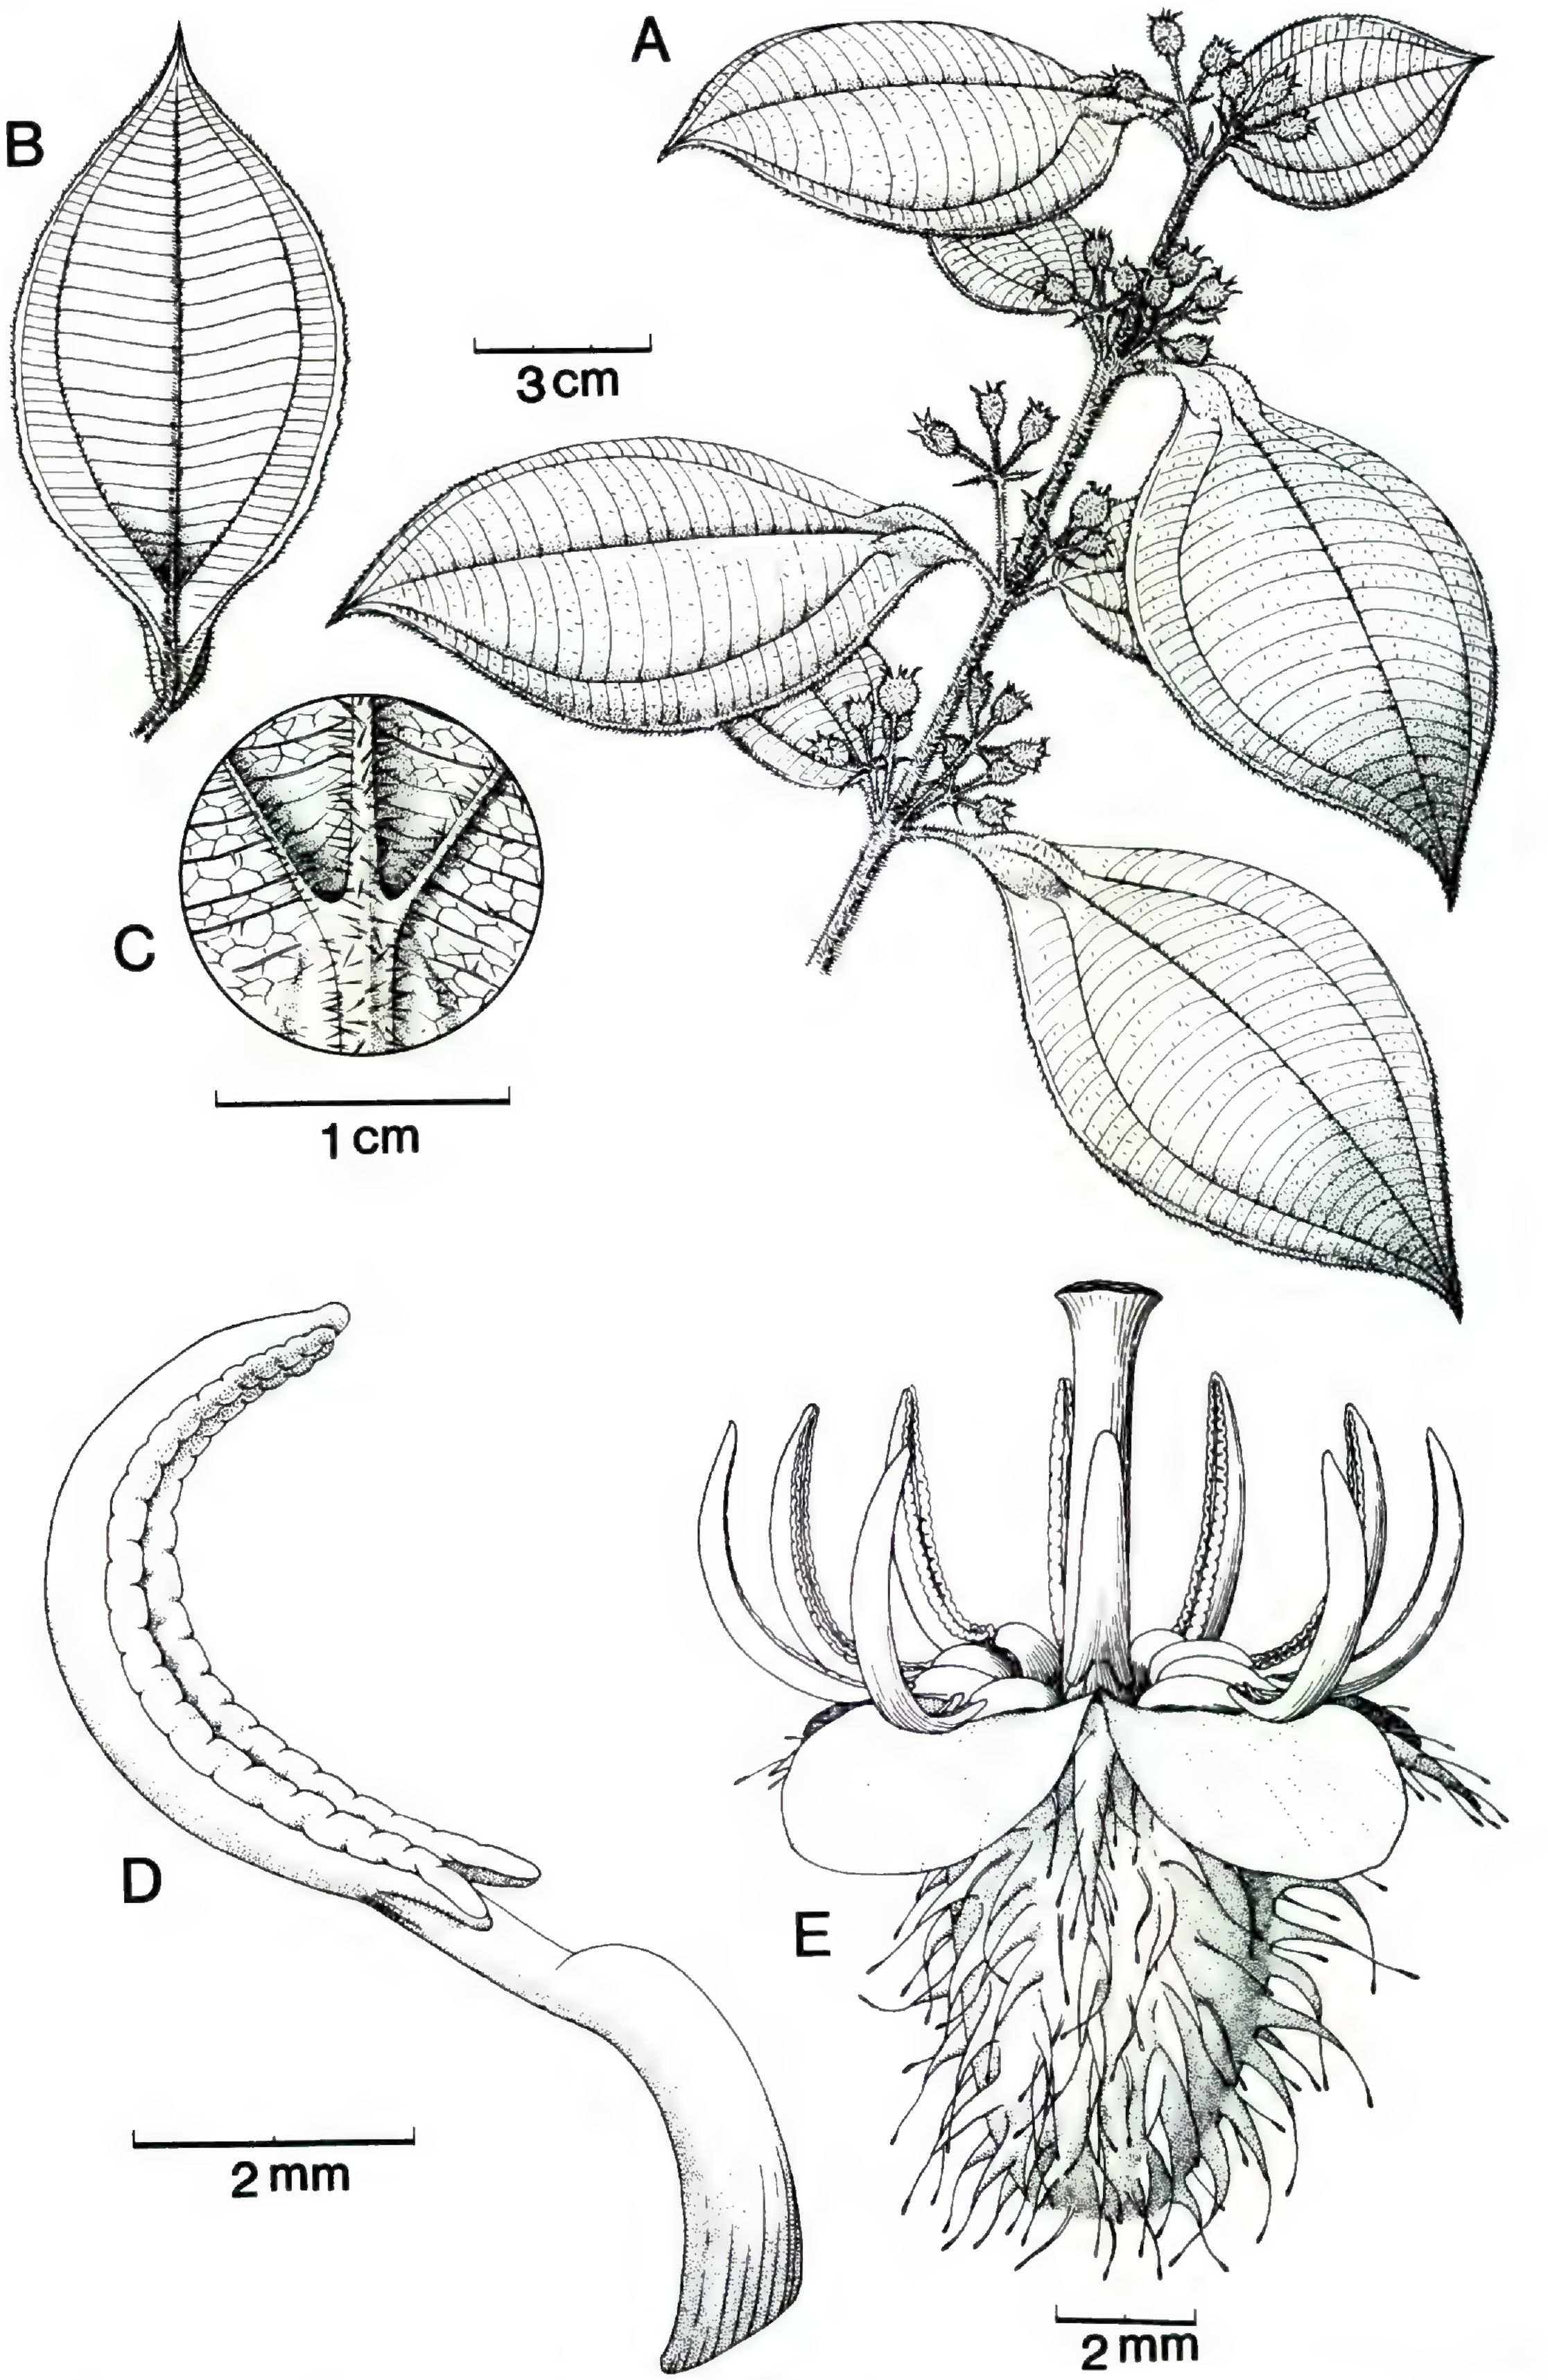

FIGURE 3. *Maieta poeppigii* Mart. ex Cogn.—A. Habit.—B. Leaf, abaxial view showing formicaria.—C. Detail showing entrance to formicaria.—D. Stamen.—E. Flower.

opposite, decussate, petiolate to nearly sessile, estipulate, herbaceous to coriaceous, ± plane; adaxial surface essentially glabrous (at maturity) or sparsely to densely covered with unbranched, elongate, multicellular hairs and sometimes also with minute glandular hairs (especially in vein impressions or at petiole junction); abaxial surface usually sparsely to densely covered with slender to stout, unbranched, elongate, multicellular hairs along with minute glandular to glandular-stellate, multicellular hairs (i.e., glandular hairs unbranched or sparsely branched with one branch glandular and the others nonglandular), sometimes only with glandular hairs and becoming ± glabrous with age; domatia not observed in vein axils; margin serrate in distal ca. ¾ of lamina to entire, plane to slightly revolute near base, the teeth ending in an elongate multicellular hair (and often associated with additional elongate hairs); venation acrodromous, slightly suprabasal, with a prominent midvein, 1–4 pairs of secondary veins (1 of these often intramarginal and inconspicuous), numerous percurrent tertiary veins ± perpendicular to midvein and reticulate to orthogonal quaternary and higher-order veinlets; petiole caniculate, essentially glabrous to densely strigose-pubescent. Inflorescences axillary cymes (occasionally reduced and ± fasciculate) borne in the leaf axils and in a few species on leafless nodes below the leaves, usually borne singly, rarely 2 per axil, bracteate, with opposite, narrowly triangular to ovate or oblong bracts (the 2 lowest protecting the inflorescence in bud and quickly caducous). Flowers perfect, 5- or 6-merous, sessile. Hypanthium ± cylindrical, abaxially with conspicuous, unbranched, elongate hairs with or without glandular apices, intermixed with minute glandular or glandular-stellate hairs, adaxially glabrous or with a few hairs around apex. External calyx lobes 5 or 6, conspicuous, elongate, terete. Internal calyx lobes 5 or 6, distinct (noncalyptrate), ± triangular, with obtuse, acute, to acuminate apices. Petals 5 or 6, ± white, narrowly triangular with acute api-

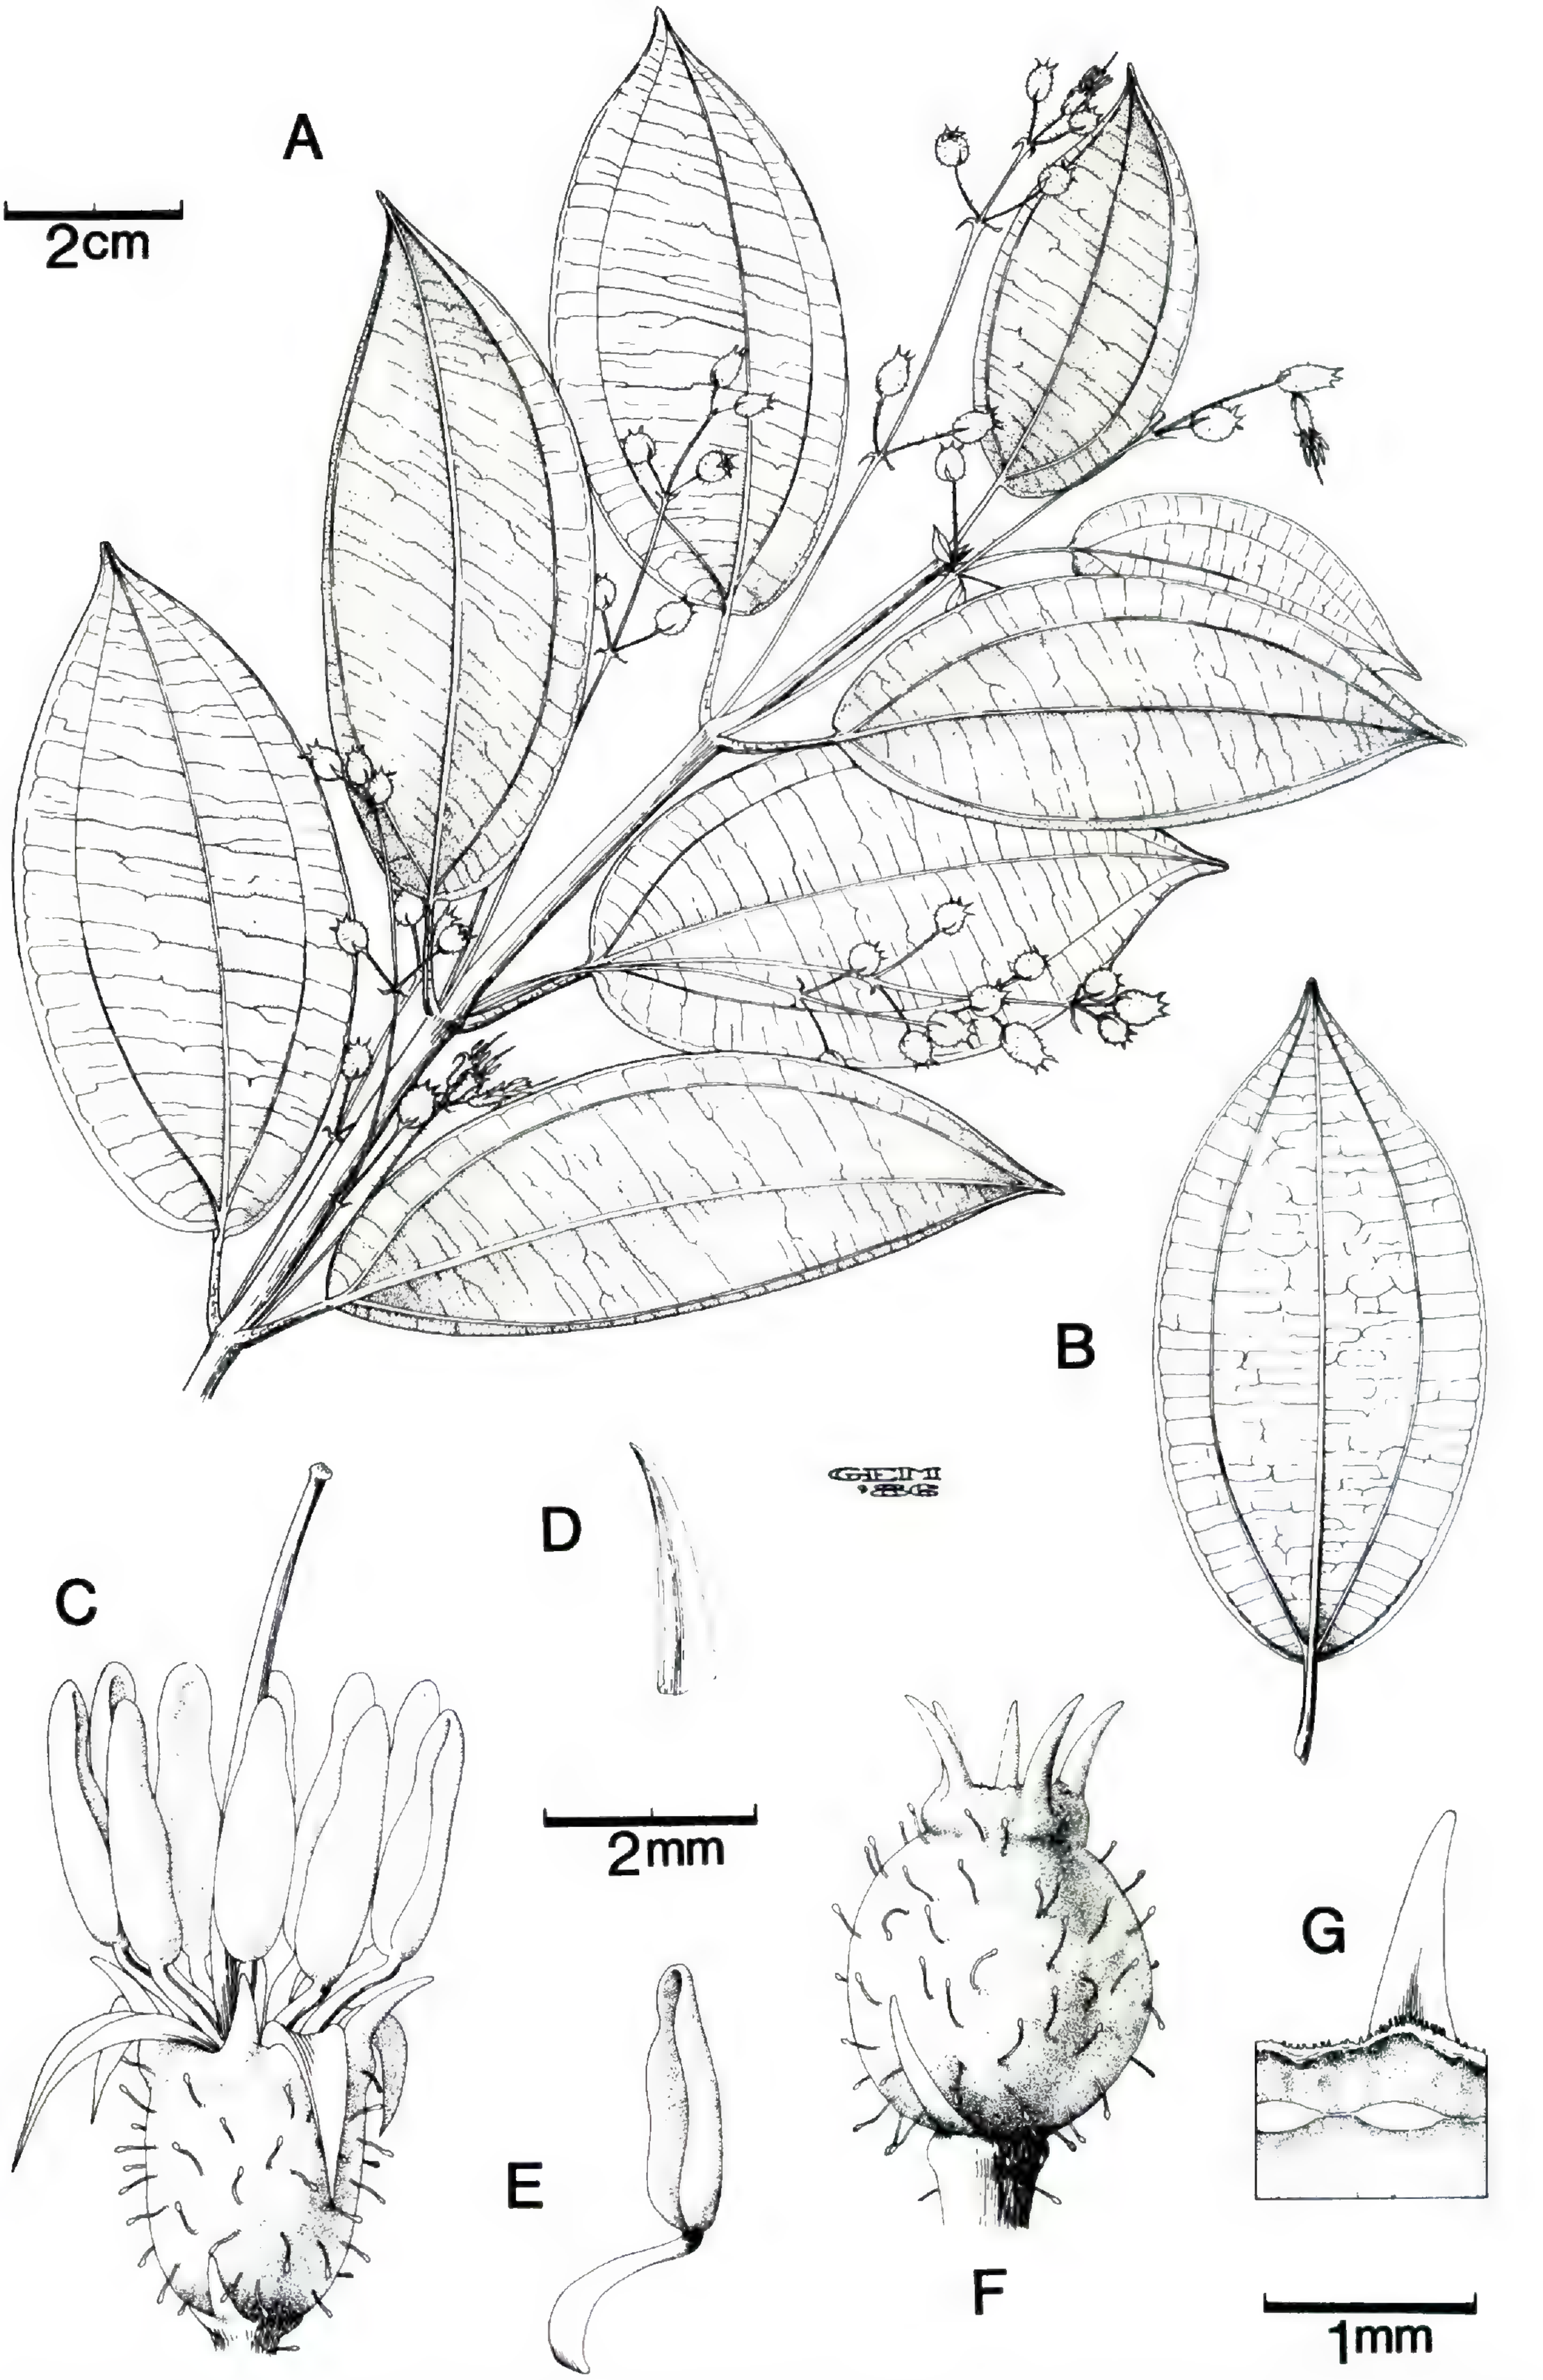

FIGURE 5. *Pentossaea coriacea*.—A. Habit.—B. Leaf.—C. Flower.—D. Petal.—E. Stamen.—F. Berry.—G. Calyx and inner surface of hypanthium; note absence of androecial fringe.

ces, 1-veined, glabrous or occasionally with a single dorso-apical projection (hair), rarely with a few glandular hairs. Stamens 10–12, ± isomorphic, glabrous, geniculate, inserted at apex of hypanthium, androecial fringe lacking; filament narrowly ovate to oblong, flattened dorsally; anther narrowly ovate to oblong, sometimes slightly curved, the 2 anther sacs dehiscing confluently by means of a single small apical pore, the connective sometimes slightly prolonged beyond the bases of the anther sacs. Ovary inferior or nearly so, 3–5-locular, with axile placentation and numerous ovules, the apex occasionally prolonged into several blunt appendages surrounding the style. Style cylindrical, ± straight; stigma capitate, papillose. Berries red to blue, with indumentum similar to hypanthium. Seeds small, rounded- to angular-obovate, the testa smooth to slightly roughened.

Pentossaea angustifolia (DC.) W. Judd, comb. nov. *Leandra angustifolia* DC., Prodr. 3: 154. 1828.

Pentossaea brachystachya (DC.) W. Judd, comb. nov. *Clidemia brachystachya* DC., Prodr. 3: 156. 1828.

Pentossaea confertiflora (DC.) W. Judd, comb. nov. *Clidemia confertiflora* DC., Prodr. 3: 156. 1828.

Pentossaea congestiflora (Naudin) W. Judd, comb. nov. *Clidemia congestiflora* Naudin, Ann. Sci. Nat. Bot., Ser. 3, 17: 344. 1852.

Pentossaea coriacea (Naudin) W. Judd, comb. nov. *Clidemia confertiflora* DC., Prodr. 3: 156. 1828.

Pentossaea heteronervis (Naudin) W. Judd, comb. nov. *Sagraea heteronervis* Naudin, Ann. Soc. Nat. Bot., Ser. 3, 18: 98. 1852.

Pentossaea marginata (Desr.) W. Judd, comb. nov. *Melastoma marginata* Desr. in Lam., Encycl. 4: 32. 1797.

Additional new combinations will certainly become necessary following a detailed revision of the genus.

The axillary-flowered 4-merous species of *Ossaea* and the very similar species traditionally placed in *Clidemia* sect. *Sagraea* (also axillary-flowered and 4-merous; see Cogniaux, 1891) are typically separated by the technical character of apically acute vs. blunt petals. However, I found this character to vary continuously within the group, and several species placed in *Clidemia* sect. *Sagraea* actually have acuminate or acute petals (e.g., *C. oligantha* Urban, *C. fuertesii* Cogn., *C. domingensis* (DC.) Cogn., *C. crossosepala* Griseb.), while others treated in *Ossaea* may have blunt-tipped petals (e.g., *O. barahonensis* Urban & E. Ekman or *O. setulosa* Urban). Some taxa have been considered members of both groups by various authors. In addition, phenetically very similar species have sometimes been placed in the two "genera," e.g., *Clidemia crossosepala* and *Ossaea hirtella* (Sw.) Triana (see Adams, 1972), and petal shape and apex occasionally vary infraspecifically, as in *Clidemia fuertesii*. Thus, all 4-merous, axillary-flowered members of the "druse-containing group" (Fig. 2) with free internal calyx lobes, no androecial fringe, and a usually well-developed strigose indumentum are placed together in *Sagraea* (Fig. 6; also see key).

Necramium (Britton, 1924), a genus with 4-merous axillary flowers having ovate, sharply acuminate petals and with an indumentum of long strigose hairs and irregularly branched-stellate hairs, clearly also belongs to this clade. A close association between *Necramium* and some species of *Ossaea* was recognized by Wurdack (1973: 721–722), who stated that *Necramium* was "realmente bien acomodado dentro de *Ossaea* DC. sensu Cogniaux pero la necesidad por una transferencia posterior cuando ese conjunto artificial se disperse se opone a la sinonimización inmediata." Wurdack (pers. comm.) suggested affinity of *Necramium* to *Ossaea* sect. *Octopleura* (Griseb.) Cogn. This is judged unlikely, however, since the latter group has terminal inflorescences (although frequently deflexed to a seemingly lateral position, see Judd, 1986a), a glandular dorso-basal connective appendage, and strongly costate fruits.

Necramium (Britton, 1924) is not the oldest name available for this clade, the names *Ossaea* and *Sagraea* (de Candolle, 1828) both having priority. Because the types of *Sagraea* (*S. capillaris* (Sw.) DC., here designated) and *Ossaea* (*O. scalpta* (Vent.) DC., here designated) fall within the group circumscribed above, and the two genera were described at the same time (de Candolle, 1828), either name is available for this group. The name *Sagraea* is chosen here, since I wish to avoid the use of *Ossaea*, a name that has been used for a great many discordant species-groups (see Wurdack, 1962, 1973, and Judd, 1986a). It is noteworthy that Triana (1871) considered these axillary-flowered species (along with a few discordant elements) to be generically separable (as *Sagraea*) from the terminal-flowered *Clidemia*.

Sagraea may be most closely related to *Mecranium*, a more specialized genus also showing 4-merous flowers, this a potential synapomorphy (15, Figs. 1, 2). *Sagraea* is considered to be metaphyletic (Donoghue, 1985; Mishler, 1985; Mishler & Brandon, 1987) because its ca. 60 species show no autapomorphies in some of the generated clado-

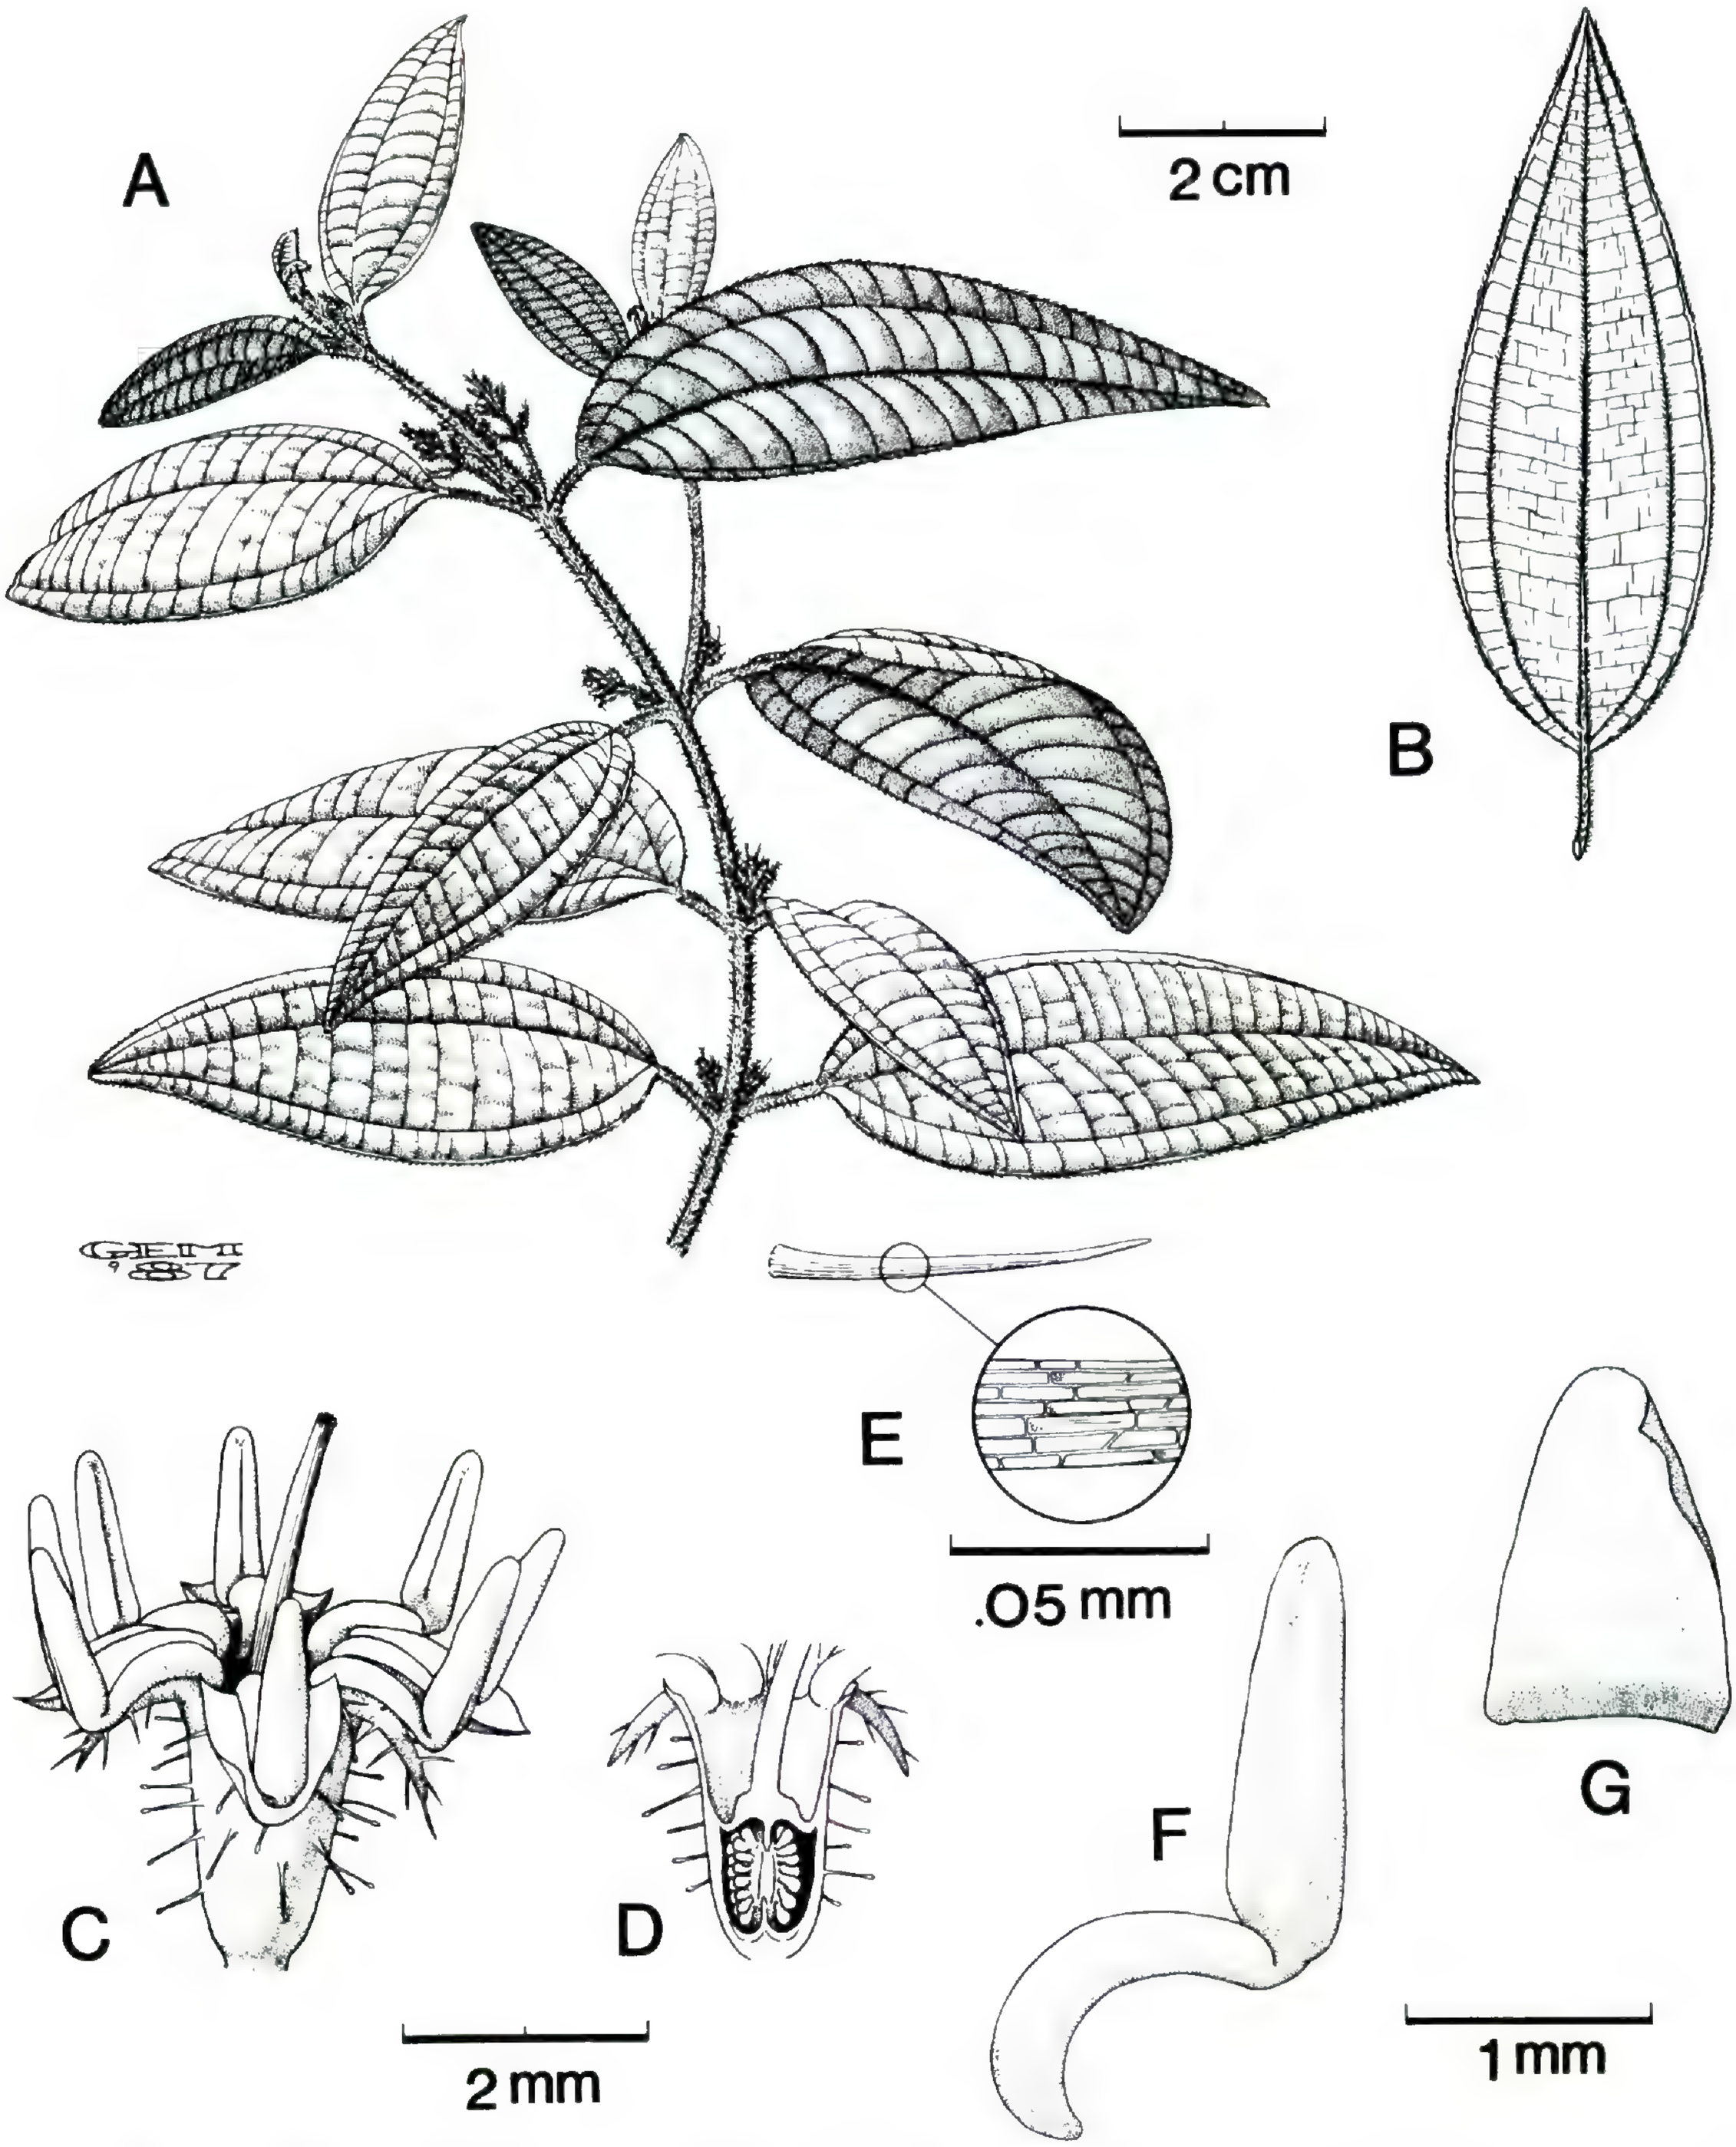

FIGURE 6. *Sagraea* (represented by the species better known as *Ossaea barahonensis*).—A. Habit.—B. Leaf.—C. Flower—D. Longitudinal section of flower showing hypanthium; note lack of androecial fringe.—E. Elongate multicellular hair.—F. Stamen.—G. Petal.

grams. However, in other equally parsimonious trees, the group appears monophyletic, being defined by a reversal to strigose hairs (5) or by a parallel evolution of 4-merous flowers (15). The group is possibly paraphyletic, but no character conclusively demonstrating this has been determined. Generic recognition of this phenetically rather variable group is considered appropriate and preferable to leaving its species in several artificially delimited genera.

Several species of *Sagraea* have evolved formicaria at the base of the petiole, e.g., *Clidemia*

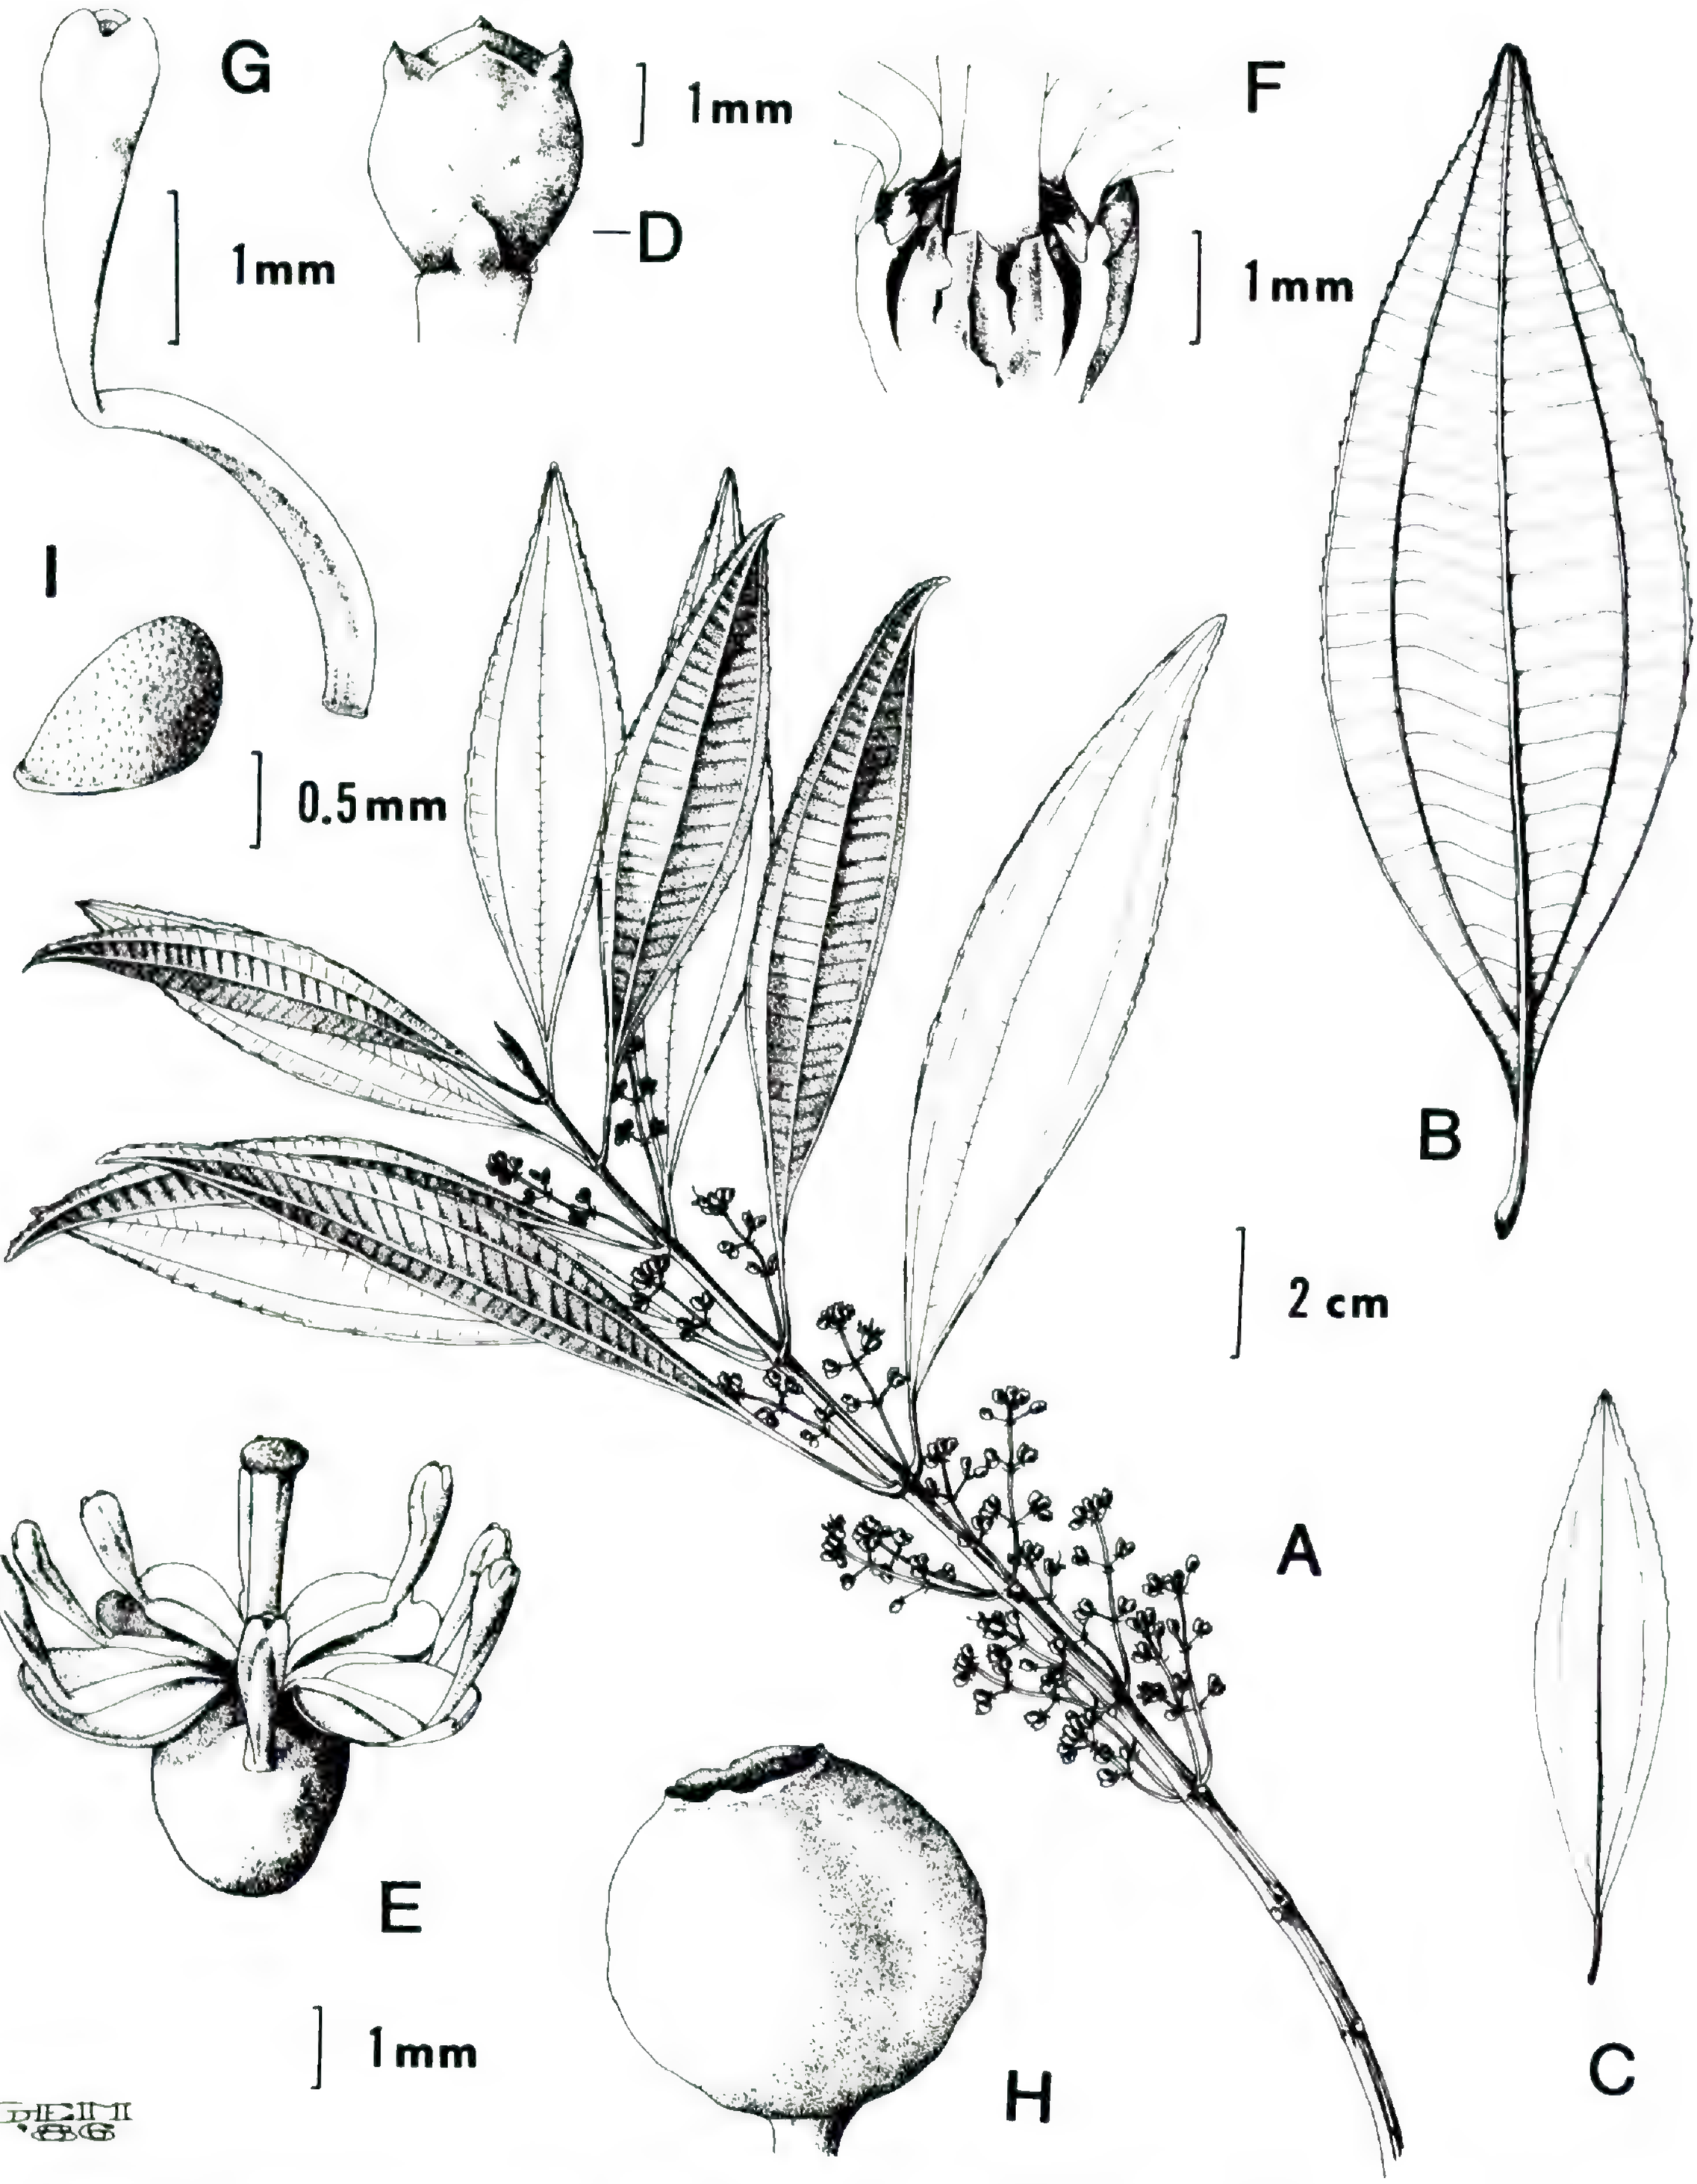

FIGURE 7. *Mecranium multiflorum* (Desr.) Triana.—A. Habit.—B, C. Leaves.—D. Flower bud.—E. Flower.—F. Hypanthium, androecial fringe, and ovary apex.—G. Stamen.—H. Berry.—I. Seed.

tococoidea (DC.) Gleason and *C. crenulata* Gleason; these species have sometimes been confused with *Maieta* (see Gleason, 1931). The structure and position of these formicaria are quite different from those of the *Maieta* and likely due to convergent evolution. Plants with a climbing habit and strongly anisophyllous leaves occur in *Clidemia epiphytica* (Triana) Cogn., a species that is also cytogenetically distinctive (Solt & Wurdack, 1980). As discussed above, anisophyllous leaves are char-

acteristic of *Maieta*, and this feature undoubtedly has evolved in parallel in the two genera.

It is not considered appropriate to make the many necessary new combinations in *Sagraea* until a thorough taxonomic revision of the genus has been completed. The species considered to belong in *Sagraea* and used in this cladistic investigation are: *Clidemia aphanantha* (Naudin) Sagot, *C. capituliflora* Cogn., *C. ciliata* D. Don, *C. crenulata* Gleason, *C. crossosepala* Griseb., *C. cursoris* Wurd., *C. discolor* (Triana) Cogn., *C. divaricata* (C. Wright ex Griseb.) Cogn., *C. domingensis* (DC.) Cogn., *C. epiphytica* (Triana) Cogn., *C. fendleri* Cogn., *C. fuertesii* Cogn., *C. graciliflora* Huber, *C. grisebachii* Cogn., *C. heteroneura* Cogn., *C. insularis* Domin (= *Sagraea capillaris* (Sw.) DC.), *C. involucrata* (Griseb.) C. Wright ex Sauv., *C. minutiflora* (Triana) Cogn., *C. monantha* L. Williams, *C. obliqua* Griseb., *C. oligantha* Urban, *C. plumosa* (Desr.) DC., *C. purpureo-violacea* Cogn., *C. pusilliflora* Cogn., *C. pycnaster* Tutin, *C. quadripetala* Almeda, *C. rubra* (Aublet) Mart., *C. rubrinervis* Cogn., *C. septulinervia* Cogn., *C. sericea* D. Don, *C. sessiliflora* (Naudin) Cogn., *C. silvicola* Gleason, *C. tococoidea* (DC.) Gleason, *C. trichotoma* C. Wright, *C. ulei* Pilger, *C. umbrosa* Cogn., *Ossaea curvipila* Urban & E. Ekman, *O. hirtella* (Sw.) Triana, *O. navasensis* Britton & Wilson, *O. nipensis* Britton & Wilson, *O. petiolaris* (Naudin) Triana, *O. rufescens* (Griseb.) C. Wright, *O. scabrosa* (L.) DC., *O. scalpta* (Vent.) DC., *O. setulosa* Urban, and *O. woodsii* W. Judd & Skean.

Mecranium (Fig. 7) is a distinctive monophyletic species group distinguished from other genera containing druse crystals by its internal calyx lobes fused into a domelike, apiculate, and membranous cap that is ruptured irregularly by elongation of the style and emergence of the petals at anthesis (22), the external calyx lobes reduced in length and often inconspicuous (reversal of 19), androecial fringe (i.e., a ring of erose to ciliate appendages arising from apex of hypanthium [torus] internal to the stamens [32]), and usually sparse and poorly developed indumentum (7); see Judd (1986a) and Skean & Judd (1986). Because these apomorphic characters are found also in the monotypic *Ekmaniocharis* (*E. crassinervis*; Urban, 1921; Judd, 1986a; Skean, in press), it is clear that this genus belongs in *Mecranium*. Likewise, *Ossaea acuminata* (Judd, 1986a) shows all these apomorphies except that of a domelike, apiculate cap. In this species the apices of the internal calyx lobes are distinct and imbricate, although the lobes are connate for most of their length, forming a structure that may be similar to the condition from which an apiculate cap was derived. It is obvious that *O. acuminata* is a basal member of the *Mecranium* clade. The nomenclatural transfers will be made by James D. Skean, Jr. in a monographic study of *Mecranium* currently near completion. A more detailed analysis of the phylogeny of this genus will be presented by Skean (in prep.).

In summary, the phylogenetic relationships (and taxonomic diversity) among the axillary-flowered Miconieae are most clearly represented by a taxonomic system recognizing the following nine genera as delimited above: *Henriettea*, *Huilaea*, *Killipia*, *Kirkbridea*, *Loreya*, *Maieta*, *Mecranium*, *Pentossaea*, and *Sagraea*.

Key to Axillary-Flowered Miconieae

1a. Plants with large elongate crystals (megastyloids) in leaf and stem tissues (easily observable with a hand lense in oblique razor blade sections); flowers usually clearly pedicellate; petals densely to sparsely pubescent abaxially, or with a few obscure hairs near apex, occasionally glabrous.
  2a. Flowers with radiately ridged, conspicuously expanded stigmas and with usually robust, fleshy anthers; indumentum of very slender to stout, elongate, unbranched, multicellular hairs ..... *Loreya*
  2b. Flowers with nonridged, less conspicuous stigmas and with nonfleshy anthers; indumentum of slender to stout, elongate, multicellular hairs with radiate to stellate-globular basal portion (or derived types, e.g., stellate hairs, peltate scales, elongate hairs with minute projections near base, or elongate hairs with a suprabasal expanded region and narrowed basal attachment).
    3a. Anthers with 2 well-developed dorso-basal projections; inflorescences clearly pedunculate ..... *Kirkbridea*
    3b. Anthers without dorso-basal projections; inflorescences usually sessile and fasciculate ..... *Henriettea*
1b. Plants with only ± spherical crystals (druses) in leaf and stem tissues, lacking megastyloids; flowers ± sessile or pedicellate; petals usually glabrous or with a single apical hair.
  4a. Flowers clearly pedicellate, i.e., pedicels ca. 1–1.5 cm long; inflorescences pendulous and 3-flowered with peduncle ca. 10–35 cm long ..... *Huilaea*
  4b. Flowers ± sessile; inflorescences various but the peduncle shorter than ca. 6 cm.
    5a. Flowers 5- or sometimes 6-merous.
      6a. Plants with pouchlike formicaria (ant-domatia) at bases of leaf blades; leaves often clearly anisophyllous ..... *Maieta*
      6b. Plants without formicaria; leaves ± isophyllous.
        7a. Petals narrowly triangular, with acute apices; plants with elongate, multicellular, un-

branched hairs (often strigose), with or without glandular tips; anthers lacking dorso-basal projections ..... *Pentossaea*

7b. Petals ovate to elliptic, with ± blunt apices; plants lacking elongate, multicellular hairs; anthers with 2 dorso-basal projections ..... *Killipia*

5b. Flowers 4-merous.

8a. Inner calyx lobes fused in a usually conspicuous, membranous dome that ruptures irregularly at anthesis; hypanthium with a ring of erose to ciliate appendages arising internally at base of stamens, i.e., an androecial fringe; indumentum usually not well developed, of minute, multicellular, globular, or unbranched to irregularly branched, and matted hairs ..... *Mecranium*

8b. Inner calyx lobes free; hypanthium lacking an androecial fringe, although occasionally with a few hairs on adaxial surface; indumentum often conspicuously strigose, almost always with elongate, branched or unbranched, multicellular hairs, often with glandular apices ..... *Sagraea*

A SURVEY OF REPRODUCTIVE BIOLOGY IN NEOTROPICAL MELASTOMATACEAE AND MEMECYLACEAE[1]

Susanne S. Renner[2]

Abstract

In the Neotropics, the Melastomataceae and Memecylaceae comprise over 3,000 species in 106 genera. Pollination observations have been reported for 126 species in 35 genera of Melastomataceae and for four species in one genus of Memecylaceae. Genetic self-incompatibility has been found in 22 Melastomataceae species, self-compatibility in 25 species. A single Memecylaceae species tested is self-compatible. Agamospermy is known in 19 New World and some Old World species of Melastomataceae. The incidence of polyploidy in Melastomataceae seems high, but only about 8% of the species have been counted. Most Melastomataceae and Memecylaceae are hermaphroditic; dioecism is known in a few species in one genus of Melastomataceae. The principal mode of promoting outcrossing in both families is spatial separation of pollen and stigma (herkogamy), achieved by the pollen being enclosed in poricidal anthers, which have to be manipulated to release pollen. New World Memecylaceae are pollinated in the same way and by some of the same bee species as most Melastomataceae. All bee species known to visit Melastomataceae and Memecylaceae are listed; they comprise a wide spectrum of the neotropical bee fauna. It is not yet clear whether the stamen dimorphism and the conspicuous connective appendages present in many Melastomataceae have a function in the pollination mechanism beyond that of enhancing the visual attractiveness of the flowers and making the stamens easier to grasp. In most Melastomataceae, flowers offer only pollen; however, some 60 species in 8 genera offer nectar as a reward for pollinators (probably, some species in at least one additional genus do, too). The nectariferous species are pollinated by birds, bats, rodents, and bees. The nectar is rich in sucrose and, as a rule, its production is correlated with floral morphological changes relating to the fact that, except for bees, nectar consumers do not vibrate the stamens to collect pollen actively. I suggest that the capacity for developing nectaries is basic in Melastomataceae but suppressed in most modern members. The staminal glands of Memecylaceae produce minute quantities of a secretion containing lipids which, however, is not collected by the pollinators; the glands may in some way enhance stamen attractiveness. In seed dispersal systems, major diversifications occurred, with 40% of the neotropical Melastomataceae having capsular fruits and wind-dispersed seeds and 60% having soft, juicy berries taken mainly by birds, but also by marsupials, monkeys, bats, other mammals, turtles, and other reptiles. All Memecylaceae have berries, and their seeds are dispersed by birds, monkeys, and fish. I conclude that the east and west Gondwanian lineages of Melastomataceae and Memecylaceae, in parallel, coevolved with the earliest bees in the lower mid-Cretaceous. This may have been the time when the ancestors of these families switched from nectar-reward flowers to pollen-reward flowers. In the further extensive radiation of both families, special adaptations to pollinators were of limited importance; diversification in seed dispersal systems, vegetative characters, and edaphic adaptations were more important.

The neotropical Melastomataceae and Memecylaceae are particularly suitable for a study of reproductive biology in view of the relative ease with which members of these families are found in the field and the availability of several recent treatments in monographs and floras. As Gleason (1932) stated, "a dozen or more species . . . grow naturally on every square mile of tropical America, unless

[1] I thank the following apidologists for identifying bees: M. C. Almeida (*Trigona*), R. Dressler (Euglossini), G. Eickwort (Halictidae), V. Graaf (*Oxaea*), C. D. Michener (Exomalopsini), S. Laroca and J. R. Cure Hakin (Halictidae), J. Moure (Xylocopini, *Monoeca*, Meliponini), D. Roubik (*Melipona*, *Trigona*), R. Snelling (Centridini, Ceratini), and D. Urban (Eucerini). Except for specimens retained by the specialists, bees are deposited in the entomological collection of the Instituto Nacional de Pesquisas da Amazônia (INPA). It is a pleasure to acknowledge the support I received at INPA, especially from Drs. W. Rodrigues, M. F. da Silva, and M. L. Absy, also from R. Bierregård and J. Rankin-de-Merona, zoological and botanical field directors, respectively, of the INPA-WWF "Minimal Critical Size of Ecosystems" project. Fieldwork in Brazil was supported by the Deutscher Akademischer Austauschdienst and the Deutsche Forschungsgemeinschaft. Fieldwork in Venezuela was funded by grants from the National Science Foundation and the Smithsonian Scholarly Studies Program. I am grateful to Klaus Kubitzki and John Wurdack for their help during different phases of this work and to T. Morley, C. Todzia, D. Roubik, H. Tobe, B. Stein, R. Lundin, and K. Bremer for comments on the manuscript.

the land is under intense cultivation, and the various genera extend from the coastal marshes at sea-level to the high páramos above the tree line." The Melastomataceae are a large family (v.i.) and diverse in terms of habit, reproductive and vegetative architecture (Cremers, 1983), and indument (Wurdack, 1986). Memecylaceae comprise about 89 species in the Neotropics and are much less diverse in these characters.

The present survey is based on my observations of the reproductive biology of many Brazilian and some Venezuelan species and on a review of the literature. The survey is presented in five sections. First, an outline of the classification and reproductive morphological features of the Melastomataceae and Memecylaceae is given; second, breeding systems and cytology are discussed; third, the pollination spectra found in the two families are described; fourth, a brief survey is made of seed dispersal in the two families; fifth, the reproductive biological information is related to the fossil record and distributional data to contribute to a better understanding of the historical evolution of the two families.

Flowering and fruiting phenology of neotropical melastomes and Memecylaceae are not dealt with here, but reference may be made to Snow (1965), Croat (1978), Opler et al. (1980), Hilty (1980), Lumer (1982), and Renner (1984 and in prep.). Suffice it to say that synchronous, episodic flowering with the episodes of short duration (a few days) characterizes some of the arborescent species of the largest genus, *Miconia*, whereas extended flowering periods (several weeks or months) are characteristic of many of the shrubs, herbs, epiphytes, and some of the tree species.

CLASSIFICATION AND REPRODUCTIVE MORPHOLOGICAL FEATURES

Worldwide, the Melastomataceae A. L. Juss. (excluding the ca. ten species of *Crypteronia*, *Axinandra*, and *Dactylocladus*, i.e., the Crypteroniaceae; Dahlgren & Thorne, 1984) and the Memecylaceae DC. consist of ca. 190 genera and approximately 4,800 species. In the Neotropics, the Melastomataceae comprise over 3,000 species in 107 genera (Table 1) and the Memecylaceae 89 species in two genera. About half of these genera contain only one to four species, whereas one genus, *Miconia*, has some 1,000 species. Though the Memecylaceae are often included in the Melastomataceae as a subfamily, it has been pointed out (see Morley, 1953; Dahlgren & Thorne, 1984; Johnson & Briggs, 1984) that the differences between these families are such that their union obscures rather than reflects our knowledge of the two groups. The Memecylaceae consist of the Asian genera *Memecylon* (ca. 300 spp.) and *Lijndenia* (4 spp.) (Bremer, 1982, 1983), the African *Spathandra* (6 spp.) and *Warneckea* (31 spp.), and the neotropical *Votomita* (8 spp.; Morley, 1963) and *Mouriri* (81 spp.). There is a consensus that the Melastomataceae and Memecylaceae belong to the core families of the order Myrtales (Dahlgren & Thorne, 1984; Johnson & Briggs, 1984).

The classification of the Melastomataceae sensu stricto is essentially that of Triana (1867), who was closely followed by Cogniaux (1891). Wurdack (1980) has realigned the New World tribes in a sequence generally resembling that of A. P. de Candolle (1828). The main dichotomy in the Melastomataceae is between the capsular-fruited and the berry-fruited genera. The genera are arranged into tribes on the basis of fruit and seed characters and the presence and position of connective appendages (D. Don, 1823; Triana, 1867; Cogniaux, 1891; Gleason, 1929; comp. also Whiffin & Tomb, 1972).

Most Melastomataceae are characterized by poricidal anthers, the connectives of which are frequently prolonged (however, species of *Miconia* sects. *Chaenopleura* and *Chaenanthera* have anthers that open by 1–2 slits). They usually have a pronounced foliar venation consisting of the midvein and one to four pairs of subparallel longitudinal veins. Memecylaceae, on the other hand, mostly have pinnate venation; their anthers open by short slits or pores. In a reproductive biological context, the presence of an elliptic, concave gland on the dorsal side of the connective is a unique feature characterizing most Memecylaceae.

The flowers in both families are actinomorphic or weakly to strongly zygomorphic as a result of movements of the stamens and style immediately after the expansion of the petals (Troll, 1922; Ziegler, 1925; pers. obs.). In Melastomataceae, the flowers are usually borne in well-developed cymose inflorescences, whereas in Memecylaceae the cymes are often condensed or reduced to a few flowers in fasciculate tufts. In both families, the mostly 4- or 5-merous flowers are perigynous or epigynous with a cup-shaped hypanthium that bears on its rim the calyx lobes, petals, and stamens. The antepetalous stamens are usually longer than the antesepalous ones, which may be staminodial; this dimorphism is more or less pronounced and has given occasion to much speculation concerning its role in pollination. In Melastomataceae with poricidal anthers, the anthers are one- or two-pored, a character that is consistent at the species level but varies within genera; there is also considerable variation in the size and position of the pores. Pollen grains are usually free, small, and rather smooth, although polyads and tetrads are known in species of *Tococa* and *Miconia* (Patel et al., 1984).

Breeding Systems

The principal mode of promoting outcrossing in most Melastomataceae and Memecylaceae is the very effective spatial separation of pollen and stigma in the flowers (herkogamy). This is achieved by the pollen being enclosed in tubular anthers with apical or subapical pores or slits, which are generally minute, and positioned well distant from the punctiform or capitate stigmas. Also, the stamens are usually shorter than the styles. In bud, the stamens are always folded over in such a way that the anther pores point downward and are maximally distant from the stigma, which lies at the tip of the bud. Thus, chances for automatic selfing before and during anthesis are very low or nil. If, however, during anthesis, an anther or the style bends in such a way that the pore is brought into contact with the stigma, automatic selfing may occur. This has been reported for *Monolena trichopoda* (Melastomataceae; Warner, 1981) where, late in anthesis, the stamens fold over and the thecae are effectively stuck to the stigmatic exudate.

No pollen escapes from the anthers unless mediated by a vector, which at least potentially may arrive bearing conspecific pollen. Almeda (1977, 1978) suggested that vigorous mechanical movement of the anthers by gusty winds or rains might release pollen in species of *Monochaetum* and *Centradenia* (Melastomataceae). Additionally, he often observed pollen in water droplets connecting anthers and stigma and suggested that this might be another possible route for selfing to occur. However, bees, which regularly collect pollen from Melastomataceae, use vibrations of around 420 Hz or higher (this frequency was found to effect ample pollen emission from the large anthers of *Bellucia*; see below). Therefore, it seems unlikely that the low-frequency vibrations produced by wind could release pollen from melastome anthers. This impression is supported by the lack of fruit set in bagged flowers of nonagamospermic species exposed to strong wind (Renner, 1984). While autogamy may be extremely rare, vector-mediated selfing (i.e., geitonogamy), a function of pollinator behavior and number of conspecific flowers available at a time, may be frequent in self-compatible species.

Temporal separation of male and female function has been suggested for species of *Monochaetum* (Almeda, 1978) in which "the ill-defined stigmatic region . . . appears to be non-receptive during the first day." This may be a rare condition because, as a rule, poricidal flowers that offer only pollen as a reward (subsequently also called "pollen-only flowers") receive foreign pollen at the same time a visitor harvests pollen from them; in female-phase flowers, there is nothing to reward visitors (only mimicry or deception might account for visits to female-phase flowers). Homogamy, i.e., the simultaneous functioning of the male and female parts, is thus to be expected in pollen-only flowers. Temporal separation of the male and female function in single flowers has been reported twice in nectariferous melastomes (Ule, 1896; Vogel, 1957); in both cases, the flowers were protandrous.

The Melastomataceae are not entirely hermaphroditic. Wurdack (1964) was the first to describe dioecism in *Miconia dioica* Wurdack; herbarium specimens of this species had female flowers with abortive stamens and male flowers with poorly developed stigmas. He also suspected dioecism in some other minute-flowered Andean species of *Miconia* (*M. dielsii* Markgraf, *M. clathrantha* Tr. ex Cogn., *M. minuta* Gleason; Wurdack, 1980: 261–262) and in *M. rubens* (Sw.) Naudin from the West Indies and Venezuela (Wurdack, 1964). Field observations on the reproductive biology of these and some other suspected dioecious melastomes are lacking.

At least one species of *Lijndenia* (Memecyla-

ceae) has hermaphrodite-flowered individuals and purely male-flowered ones (Bremen, 1982).

GENETIC COMPATIBILITY

As shown in Table 2, genetic self-incompatibility occurs in at least 22 species in the two families. As Darwin remarked (in a letter to J. D. Hooker on Nov. 28, 1871, in F. Darwin (ed.), 1903), melastomes "are troublesome beasts to fertilise." This is due to the closed anthers and mostly punctiform stigmas. In some large-flowered species, such as *Bellucia* (Melastomataceae), it is possible to collect large amounts of pollen for experimental purposes by holding a tuning fork to the stamens. Self-compatibility is found in 26 species (Table 2). Since no efforts have ever been made to distinguish pseudogamy from self-compatibility, several of the supposedly self-compatible species reported earlier (Darwin, 1876; Ziegler, 1925) may have set fruit as a result of agamospermy rather than of self-fertilization. Related species such as *Tococa guianensis* and *T. bullifera* or *Centradenia grandiflora* and *C. paradoxa* (all Melastomataceae) differ in their compatibility conditions (Table 2). The humid stigmatic surface and the binucleate pollen of the Melastomataceae and Memecylaceae (Tobe & Raven, 1984) indicate that the incompatibility system is gametophytic (Nettancourt, 1977).

AGAMOSPERMY

Experimental proof of agamospermy in melastomes is readily obtained by cutting off the style in freshly opened unvisited flowers. (To ensure that flowers are unvisited before the style is cut off, they must be bagged the evening before.) Apart from the 22 apomictic Melastomataceae listed in Table 3, polyembryony, with additional embryos being formed by nucellus or suspensor cells, has been reported from the Asiatic species *Osbeckia hispidissima* Wight, *Sonerila wallichii* Benn., and *Melastoma malabathricum* L. (Subramanyam, 1942, 1944, 1948). Polyembryony is often correlated with agamospermy (Gustafsson, 1946–47). *Mouriri nervosa* is the only member of the Memecylaceae so far tested for agamospermy, with negative results (Renner, unpubl.). In several of the neotropical species showing apomixis, for instance in *Clidemia novemnervia* and *Macairea theresiae*, the anthers contain very few pollen grains. In cultivated neotropical *Leandra cordifolia* Cogn., Subramanyam (1942) also found that a low percentage of fertile pollen grains was combined with the frequent formation of two embryo sacs. In most neotropical species, agamospermy is correlated with low stainability of fresh pollen in cotton blue with lactophenol. This stain indicates presence of callose, a saccharide found in the intine of pollen. Lack of an intine could make a grain unviable and is usually accompanied by lack of cytoplasm. However, in *Aciotis acuminifolia* and *Miconia argyrophylla*, pollen grains stain heavily, yet these species are capable of producing seeds apomictically. In *Clidemia novemnervia* and *Maieta poeppigii*, the stamens do not unflex completely upon anthesis but remain curved, and are thus not available for legitimate bee pollinators. Both species regularly set seeds apomictically.

Lumer (1982) observed that *Blakea gracilis*, *Blakea* sp. (originally identified as *B. grandiflora*), and *Topobea brenesii* ripened a large number of seedless fruits from emasculated flowers; however, in *T. pittieri*, she found that of the bagged flowers, 35% produced mature fruits containing seeds. Darwin (1876) and Ziegler (1925) observed fruit set in cultivated plants of *Monochaetum*, *Tibouchina*, *Centradenia*, *Calvoa*, and *Dissotis* in the greenhouse. Assuming that there were no bee pollinators in the greenhouses, it is likely that such fruits resulted from agamospermy rather than from autogamy, which, as pointed out above, is mechanically difficult in Melastomataceae.

The number of species investigated is still too small to draw firm conclusions about correlations between habit, habitat, and breeding system. Of the agamospermous species, 13 are shrubs of various types of savannas or of secondary vegetation; five are treelets, two are herbs, and one is a climber. The sample is clearly biased towards shrubby species, however, because of their accessibility.

CYTOLOGY

Some 300 of the over 3,000 species of neotropical Melastomataceae and only one species of Memecylaceae (*Mouriri myrtilloides*) are known cytologically (Solt & Wurdack, 1980). Only a few of these have been examined twice. Melastome chromosomes are very small (0.5–1 micron; Solt & Wurdack, 1980) and stain poorly. The most common base numbers are 9 and 17 (Wurdack & Kral, 1982). Based on Solt & Wurdack's results, the incidence of polyploidy in the Melastomataceae seems high. It cannot yet be answered whether polyploidy is more frequent in species with strong agamospermous reproduction than in those which lack apomixis, nor whether there is a correlation between polyploidy and growth habit.

POLLINATION SYSTEMS

In neotropical Melastomataceae and Memecylaceae, the most widespread pollination system

involves female bees; it occurs in an estimated 98% of the species. Pollination by hummingbirds, bats, and rodents is found in an estimated 60 species of *Meriania*, *Centronia*, *Brachyotum*, *Tibouchina*, *Miconia*, *Huilaea*, *Chalybea*, and *Blakea* (Table 4), and probably also in *Axinaea* (see below). The mode of pollination is determined by the type of reward offered: Melastomataceae and Memecylaceae with pollen-only flowers are, as a rule, pollinated exclusively by bees because the morphology of the anthers excludes all other pollen-collecting vectors. In contrast, the nectar-offering species attract a wide variety of pollinators.

MELASTOMATACEAE

POLLINATION BY POLLEN-COLLECTING BEES

a) Methods of pollen collection and kinds of bees

Pollination by bees has been reported for some 120 species in 31 genera of Melastomataceae (Table 4). In addition, a few species occurring at Finca La Selva, Costa Rica, and near Kourou, French Guiana, have been observed to be pollinated by small and medium-sized bees (Bawa et al. 1985; Roubik, 1979a). Many unidentified melastomes are indicated as visited by bees in apidological studies (e.g., Sakagami et al., 1965, and Roubik, 1979b).

[1] "Important pollinators" excludes the numerous *Trigona* species, which are omnipresent pollen scavengers on Melastomataceae. Note that "halictids" stands for many different species, the correct names of which cannot be ascertained at present.

Bees gathering pollen from Melastomataceae flowers must be able to shake it out of the anthers or else pull pollen grains out through the pores with their tongues. This latter mode of exploiting melastome flowers is used by a group of *Trigona* bees and does not usually result in pollination because these bees are too small to contact the stigmas. Another subgroup of *Trigona* bees, characterized by having toothed mandibles, cuts up melastome anthers and robs their pollen (Laroca, 1970; Renner, 1983).

The method of pollen collecting used by all other bees to extract pollen from melastome anthers was first described correctly by van der Pijl (1954). When approaching a flower, in flight, the bees orient themselves with the group of stamens and the style and then straddle the stamens. They usually grasp the filaments or the bases of the anthers, quite often using their mandibles. Therefore, after having been visited, flowers often show necrotic spots on the outside of the stamens where the bees held onto them. When the bees position themselves over the androecium, their potentially pollen-bearing surface contacts the stigma even before they start exploiting the anthers. Also, they strive to establish a firm contact with as many stamens as their body size permits, going to considerable efforts in order to bundle all 8, 10, or 12 stamens. Close contact between the bee and the stamens is necessary for pollen collection by means of thorax vibrations, which are transmitted to the stamens and cause the pollen to stream out of the anther pores. Electrostatic forces due to the net positive charge of the bees and the negative charge of pollen greatly aid pollen-load adhesion (Thorp, 1979). When a pollen load, taken with forceps from a freshly captured bee, is released near this bee, it jumps back onto it (pers. obs.). The very rapid distortions of the thorax-box (with the wings at rest) are made possible by the unique contractile properties of the bees' fibrillar indirect flight muscles. Pollen collecting by this method is always accompanied by a characteristic buzzing sound and has been termed "buzzing method" (van der Pijl, 1954; Michener, 1962).

The rapid vibrations used when harvesting melastome pollen presumably produce a high temperature of the flight muscles, which may mean that this method of pollen collecting is particularly appropriate during the relatively cool early morning hours. Also, there are ecological constraints on the activity of dark-colored bees during the hottest hours. Buzz pollination continues with very high humidity of the air and even during slight rains.

In most melastomes, pollen deposition and reception is on the lower abdomen (sternotribic) or lateral on the bees (pleurotribic); it is on the back (nototribic) in a few species with downwards-curved styles (e.g., species of *Meriania*, *Adelobotrys*, *Salpinga*) and in *Desmoscelis villosa*. In these cases, bees assume quite unexpected positions in order to vibrate the stamens; in *Adelobotrys rachidotricha*, for instance, they buzz with the head pointing outward and downward. Relatively large flowers, such as those of *Blakea*, *Topobea*, and *Bellucia*, are exploited by a wide range of bees (Lumer, 1982; Renner, 1986/1987). For example, stamens of *Bellucia* are vibrated by 33-mm-long *Centris* and 8-mm-long *Augochloropsis* bees. In the case of self-compatible species, visits by bees too small to contact the stigma and deposit foreign pollen may still result in self-pollen landing on the stigma when such small bees vibrate one or a few stamens.

Bees visiting Melastomataceae exhibit considerable steadiness during individual foraging flights: pollen loads often consist of almost pure melastome pollen with very few grains from nectariferous flowers or with grains from *Cassia* mixed in (Renner, 1984). *Cassia* has buzz-pollinated flowers, and bees often visit several such flowers (see below).

In Brazilian Amazonia, I have captured 80 species of bees, including the Africanized honey bee, *Apis mellifera scutellata* Lepeletier, vibrating melastomes. (A list of all bees, including the species of *Trigona*, may be obtained upon request.) Additional species have been captured in extra-Amazonian areas and at higher altitudes. To date, at least 100 species of bees have been found pollinating melastome flowers (Table 4; this does not include the numerous species of pollen-scavenging *Trigona* bees). The relatively few groups of bees that have been successful in tropical forest environments, the euglossines, halictids, *Xylocopa*, and *Melipona* (Michener, 1979) are the most important pollinators of lowland melastomes. In savannas, Centridini, Oxaeidae, Exomalopsini, and *Ptiloglossa* (Colletidae) become important, as do bumblebees in southern Brazil and at higher altitudes. The bee fauna in neotropical forests and savannas is still incompletely known; however, based on bee inventories in Panama, Costa Rica, French Guiana, Surinam, and at the mouth of the Amazon (Heithaus, 1979; Roubik, 1979a, b; and ref. in Michener, 1979), it may be estimated that only about 300 species of bees occur in these forests, a number that includes non-flower-visiting parasitic and leaf-cutter bees. Thus, between 80 and 100 species collecting pollen from Melastomataceae represents a high proportion of the total Amazonian bee fauna.

b) Floral attractants

Melastome pollen is an important pollen source for neotropical bees. This is clear from a survey of literature on bee foraging: it is collected by female euglossines (Moure, 1970; Janzen, 1971; Michener et al., 1978; Roubik, 1979a, b; Dressler, 1982; Renner, 1984), meliponines and halictids (Ducke, 1901, 1902; Laroca, 1970; Roubik, 1979a, b; Michener et al., 1978; Absy & Kerr, 1977; Absy et al., 1980), mixed with Malpighiaceae oil by anthophorine bees (Vogel, 1974; Renner, 1984), and makes up 96–100% of the nest provision of the colletid bee *Crawfordapis* (Roubik & Michener, 1985). A chemical analysis of *Bellucia dichotoma* pollen revealed high nitrogen and total crude protein. (I am indebted to S. Buchmann for analyzing a pollen sample in 1983.) In this species, the pollen has a strong perfume resembling that of the flowers.

Secondary attractants for bees include sweet or perfumelike floral odors produced by the petals, the connective, and the upper section of the style (as determined by neutral red staining; pers. obs.; method, Vogel, 1963), and the presence of a landing platform provided by the androecium. I have never seen bees land on the petals. Frequently, the filaments are adorned with glandular or eglandular hairs, which may make them easier for the bees to grasp. Also, direct alighting on the stamens may make visits to flowers with poricidal anthers particularly rewarding compared with flowers requiring further crawling and searching after landing.

Most Melastomataceae seem to be visited and pollinated early in the morning, sometimes 20 minutes before sunrise (F. Mueller, 1873; Frankie, 1976; Lumer, 1982; Renner, 1984), and many species close their petals by late morning. However, flowers of *Monochaetum* and *Rhynchanthera* open late, two to four hours after sunrise (Almeda, 1978; pers. obs.). Shedding of the flower parts usually starts at the end of the second day. Again, *Monochaetum* differs in having flowers that stay open for three days (Almeda, 1978), and I have seen *Graffenrieda fruticosa* flowers staying attractive for at least seven days. In the latter case, the adverse climatic conditions at 2,200 m altitude, where *Graffenrieda fruticosa* occurs, may place a high selective advantage on longer flowering periods which presumably heighten the flowers' chances of being visited.

The typical bee colors of most Melastomataceae flowers, white, purple, or pink, are due to total reflection and anthocyanins (Lowry, 1976; Bobbio et al., 1985). Yellow and orange flowers evolved repeatedly in isolated species throughout the family. Contrasting marks at the base of the petals and color changes during anthesis are frequent in Melastomataceae (F. Mueller, 1873; Ule, 1896; Wurdack, 1980; Renner, 1984). The colors change from white to red, from yellow to red, from white to purple, or from pink to white. The bright white of the small flowers of many herbaceous understory melastomes, e.g., species of *Aciotis*, *Leandra*, *Clidemia*, *Miconia*, and *Ossaea*, may be of selective advantage under conditions of low light intensity. Some melastome flowers tested (using a Kodak 18A Wratten filter) did not absorb ultraviolet light (Lumer, 1982), as was to be expected from the absence of flavonols from their petals.

The androecia of many species in the capsular-fruited tribes Merianieae, Bertolonieae, Microlicieae, Tibouchineae, and Rhexieae show a strong morphological differentiation into two sets of stamens. In addition, in such flowers the connective appendages may be large and stiff, forming 5, 10, or 15 usually yellow spurs, sometimes positioned like true anthers. Based on his brother's (Fritz Mueller) observations on a southern Brazilian species of "*Heeria*," Hermann Mueller (1881, 1883) was the first to suggest that this dimorphism was the ultimate result of a "division of labor" between the two sets of stamens (his illustration shows that his brother was probably dealing with a species of *Microlicia*; *Heeria* is synonymous with *Heterocentron*, which does not occur in southern Brazil). According to this idea, the conspicuous anthers attract the bees and offer "food pollen" as a reward, whereas the less conspicuous ones contain "functional pollen." The "functional pollen" is supposed to be placed on a part of the bee where it will not be groomed off and used as food for larvae. It will instead function in fertilization. Hermann Mueller's idea caught on immediately (Forbes, 1882; F. Mueller, 1883) and is usually mentioned as typical of the pollination strategy of Melastomataceae (e.g., Cammerloher, 1931; Percival, 1965; Kugler, 1970; Proctor & Yeo, 1972; Baker, 1978; Faegri & van der Pijl, 1979).

A partitioning of the bee surface would be necessary for selection to favor the pollen grains from one set of stamens over those from the other and thus lead to pollen dimorphism. Pollination mechanisms involving vibration of anthers, however, may not allow a sufficiently precise placement of pollen from two sets of stamens on bees. Forbes (1882), working with unnamed species of *Melastoma*, reported that "only the pollen from the long stamens seemed [sic] to be fertile"; yet he found pollen from both types of stamens on the stigmas. To date, with the exception of Forbes's report

(1882), no morphological or physiological differences between pollen grains from dimorphic stamens have been found in any of the Melastomataceae studied (Darwin, 1876; Ziegler, 1925; Whiffin, 1973; Almeda, 1977; Renner, 1984). Further experimental fieldwork is needed to assess whether the staminal dimorphism and the stamen appendages have a function beyond that of enhancing the visual attractiveness of the flowers and making the stamens easier to grasp for bees. In view of the importance of pollen aromas for guiding bee behavior (cf. Dobson, 1987), it is uncertain if the visual cues provided by the yellow connective appendages by themselves elicit pollen-collecting behavior.

POLLINATION OF NECTAR-PRODUCING MELASTOMATACEAE BY BIRDS, BATS, RODENTS, AND BEES

Some 60 species of *Meriania*, *Centronia*, *Brachyotum*, *Tibouchina*, *Miconia*, *Huilaea*, *Chalybea*, and *Blakea*, all of them, except the species of *Miconia*, occurring at higher altitudes (1,600–3,400 m), offer nectar as a reward for their pollinators. On the basis of their character syndrome (see below), *Meriania drakei* (Cogn.) Wurd., *M. furvanthera* Wurd., *Axinaea weberbaueri* Cogn., and several other species of *Meriania*, *Axinaea*, *Centronia*, and Tibouchina are expected to produce nectar, too.

The first reports on nectar production in melastomes are by Ule (1895, 1896). In three species of *Tibouchina* (Table 4) growing on the Brazilian Itatiaia mountain range, he observed that nectar was produced by the staminal vascular bundle and secreted either directly from the filaments or sometimes through a slit in the filaments. He suggested bumblebees as the probable pollinators of these species. At Ule's request, the chemist T. Peckolt analyzed the stamens of another species that did not secrete nectar (Ule gave the name as *T. glareosa* Cogn.; there is no such name, and he probably meant *T. granulosa* Cogn.). Peckolt found that sugar was present "in great quantity," which suggested to Ule (1896) that this was likely true for other species of *Tibouchina* as well. In several other nectariferous melastomes, slits in the upper ventral side of the filaments have been observed, e.g., in *Tibouchina cleistoflora* Ule (Ule, 1896; pers. obs.), *T. grossa*, *Blakea chlorantha* (Tobe et al., in prep.), *Brachyotum ledifolium*, *B. andreanum* Cogn., *B. benthamianum* Triana, and *B. rugosum* Wurd. (Lagerheim, 1899; pers. obs.). They have also been found in non-nectariferous species—such as *Centradenia grandiflora*, *Heterocentrum roseum*, *Triolena pustulata* (as *Bertolonia pubescens*)—and in paleotropical species of *Dissotis* and *Medinilla* (Ziegler, 1925). These slits appear not to be consistently formed sutures, but rather spontaneous ruptures. The anatomy of the nectariferous tissue is being studied by Tobe et al. (in prep.).

Reports of nectar in *Miconia minutiflora* (Mori & Pipoly, 1984) are unclear, since its presence in the minute flowers (2.5 mm in diameter, style 4 mm long) was only presumed. In central Amazonia, where I have observed this species, it did not produce nectar (Renner, 1984). However, in another *Miconia* species in the Belém region at the mouth of the Amazon, Roubik measured floral nectar of ca. 20% sugar concentration and collected *Melipona* and *Apis* (!) bees (Roubik, pers. comm. 1987). Recently, nectar production has also been confirmed in the Antillean endemics *Miconia sintenisii* Cogn. and *Mecranium amygdalinum* (Desr.) Wright (Dent, pers. comm.). *Miconia robinsoniana*, also with minute white flowers, was included under "nectar sources" in a summary of flower records for *Xylocopa darwinii* by Linsley et al. (1966). McMullen, who made further observations on the floral visits of this bee on Galápagos (McMullen, 1985), has never noticed any nectar in *M. robinsoniana* (McMullen, pers. comm., 1987).

Except in *Miconia*, nectar production in Melastomataceae is correlated with floral morphological changes that relate to the fact that the nectar collectors do not vibrate the stamens. Therefore, when nectar instead of pollen is the pollinator reward, the latter must be deposited on a visitor during nectar uptake. This is achieved by the anthers having rather large pores and being stiffened, particularly at the base. Pressure on the base of the anthers exerted by the head of a bee, the bill of a bird, or the front paws of rodents clasping the flowers ejects pollen onto the visitor. Lagerheim (1899) therefore speaks of "bellow" anthers; he found that a match the thickness of a hummingbird bill pushed into the flower of *Brachyotum ledifolium* so that it pressed the anther bases brought forth a pollen cloud 3 cm long. The flowers of the nectariferous species are inclined or pendent and, in the case of the bird-pollinated ones, usually dark red, deep purple, or bluish to almost black. In *Brachyotum ledifolium* the petals are yellow, but the hypanthium is covered with bright red hairs. In nectariferous melastomes, the petals do not spread at anthesis but remain convolute almost like in bud. Vogel (1957) reported a nocturnal cabbage odor in the predominantly bat-pollinated *Tibouchina grossa*. The other nectariferous melastomes are reported as scentless.

The bulk of nectariferous melastomes seem hummingbird-pollinated (Table 4). Most of them belong to the genus *Brachyotum*, which comprises 50 species, the majority ornithophilous (Wurdack, 1965, 1980; Lagerheim, 1899; Vogel, 1957; Fitzpatrick et al., 1979; label data). Other bird-pollinated species are *Meriania tomentosa* (Cogn.) Wurd. (*Centronia excelsa* (Bonpl.) DC.; van der Werff, pers. comm.; D. Neill, pers. comm.). Nectariferous and hummingbird-pollinated species in the Miconieae are *Huilea macrocarpa*, *H. penduliflora* (Snow & Snow, 1980) and probably also *Chalybea corymbifera* (in which Stein observed nectar but no pollination events; pers. comm., 1987). The Colombian *Tibouchina grossa* is pollinated by bats and hummingbirds (Vogel, 1957; Stein, pers. comm., 1987) and certainly the same is true of *T. Stricta* Wurd. and *T. reticulata* Cogn.

New World rats and mice of the tribes Peromycini and Oryzomini pollinate at least three nectariferous species of *Blakea* in Costa Rica (Lumer, 1980, 1982; Lumer & Schoer, 1986). Lumer found that bees and hummingbirds rarely visited the flowers of these species during the day but that nectar secretion was nocturnal. The *Blakea* species involved are hemiepiphytic, and their flowers are positioned close to the stem where the rodents can reach them conveniently.

The nectar of *Blakea chlorantha* contains ca. 11% sucrose (Lumer, 1982, and pers. comm.); that of *Huilea macrocarpa* has 12–16% with a mean of 13.4% (Snow & Snow, 1980); that of *Chalybea corymbifera* 16.5%; and that of *Brachyotum ledifolium* 20–22% (Tobe et al., in prep.). It would thus be classified as relatively rich in sucrose in the nectar class system of Baker & Baker (1983), who found that sucrose-rich or sucrose-dominated nectar prevails in hummingbird flowers. Thus, nectariferous melastomes offer a reward "intended" for pollinators other than bees.

The evolutionary origin of pollination systems involving nectar in Melastomataceae is considered below.

MEMECYLACEAE

In their pollination mechanism, the neotropical Memecylaceae closely resemble the Melastomataceae, and the above description of bees' methods of pollen collecting from melastome flowers also applies to them. In *Mouriri*, the anthers are stiff, with thickened endothecial walls, and are slightly prolonged just above the insertion of the filaments. The prolongations, termed "caudae" (Morley, 1953), are used as footholds by the bees exploiting *Mouriri* anthers. Pollination in four species of *Mouriri* has been observed (Table 4); the main pollinators seem to be euglossines, followed by *Xylocopa* and *Melipona* species. They are legitimate visitors, i.e., large enough to contact the stigma regularly while collecting the reward. Memecylaceae anthers differ from those of Melastomataceae in bearing dorsal concave glands, 0.3–0.8 mm long. (For illustrations of the permutations in size and position of these glands in *Mouriri* and *Votomita*, see Morley, 1953, 1976, and 1985.) None of the legitimate pollinators show any interest in the staminal glands (Buchmann & Buchmann, 1981; Renner, 1984, and unpubl.).

Earlier (1984), I reported that *Melipona marginata* and *M. fulva* sometimes collected the secretion from the glands with the front legs, and that they mixed this substance with their pollen loads between pollen-collecting bouts on the wing. Further field observations, however, have convinced me that *Melipona* does not regularly touch the glandular surface when buzzing. The bees grip the stamens by the anther caudas just below the glands, and it is difficult to see what they do with their feet or their mouth parts when vibrating because they curve tightly over the anthers to allow the pollen stream to settle on their bodies. Between buzzing bouts, *Melipona* bees (and the euglossines) rotate over the androecium so as to drum out the pollen from all ten anthers. Staining of their freshly collected corbicular loads with Fehling solution showed that the pollen had been wetted with sugar. With Sudan III (a lipid stain), *Mouriri* pollen grains stained red, but the secretion holding them together did not; this implies that the pollen contains lipids, whereas the secretion did not.

Mouriri flowers are also visited by several species of *Trigona*. These small bees do not regularly contact the stigma but rob pollen from the anthers, which they are unable to buzz. Their role as pollen scavengers and robbers in Melastomataceae is well known (Renner, 1983). When cutting up anthers of *Mouriri nervosa* to reach pollen grains further down, *Trigona williana* very rarely touched the glands (Renner, 1984, and unpubl.). Most often, *T. williana* cut off the anthers above the glands, then stopped and started cutting and robbing the pollen of another anther. This shows that this pollen robber, like the legitimate pollinators, does not regularly collect the glandular exudates. Buchmann & Buchmann (1981) have observed *T. pallens* manipulating the glands of *M. myrtilloides* with the front legs and mouth parts.

The secretion of the staminal glands is yellow, viscous, stains red in Sudan III, and tests positive

for fatty substances. That of the relatively large (0.8 mm long) glands of *M. lunatanthera* forms myelin figures in water after a drop of sodium hydroxide is added (pers. obs.; method from Vogel, 1974). The secretion in *M. myrtilloides* has been reported to be a lipoidal mixture of many compounds (e.g., phenolic compounds, small amounts of glucose and saponin, at least 13 fatty acids, and free fatty acids) and to be "extremely rich in non-lipid constituents" (Buchmann & Buchmann, 1981).

Since the secretions from the floral glands contain lipids, the relationship between *Mouriri* and oil-collecting bees is of particular interest. Floral oils are collected by bees belonging to relatively few genera of Anthophoridae (e.g., *Centris*, *Epicharis*, *Monoeca*, *Paratetrapedia*, *Tapinotaspis*, *Tetrapedia*; cf. Vogel, 1974; Neff & Simpson, 1981). Although many of these collect pollen from Melastomataceae (comp. Table 4), to date only a single anthophorid bee species, *Paratetrapedia calcarata*, has been observed on *Mouriri* (Buchmann & Buchmann, 1981). This bee, due to its small size (7–8 mm long), rarely vibrated more than two or three of the ten anthers in each flower and only rarely touched the stigma (l.c.). Also, Buchmann & Buchmann (1981) reported that *Paratetrapedia calcarata* was an infrequent visitor of *M. myrtilloides* (16 times during 50 hours) and not a legitimate pollinator.

The secretion of the staminal glands forms a shiny film on the gland cuticle and in this respect differs greatly from the lipid-filled blisters of other epithelial elaiophores (Vogel, 1974). *Paratetrapedia* has scrapers on the fore-basitarsi (Neff & Simpson, 1981) and ruptures the cuticle of the elaiophores from which it collects oils. While scrutinizing hundreds of stamens from *Mouriri nervosa* and *M. guianensis* under the stereoscope in order to collect their glandular secretions, I never found signs of the glands having been scraped. This was perhaps to be expected, since the secretion forms a film on the outside of the cuticle.

A further problem in understanding the role of the staminal glands is that they are so small and positioned in such a way that the collection of any exudate either with the fore-basitarsi or the mouth parts by the medium-sized bees that pollinate *Mouriri* is difficult to envisage. Visitors small enough to be attracted by the minute quantities of secretion offered (such as the *Paratetrapedia* species observed by Buchmann & Buchmann, 1981) are not large enough to touch the stigmatic surface when manipulating the glands, especially since the styles in *Mouriri* are always longer than the stamens and the stigmas are held well away from the anthers.

A possible role of the staminal glands suggested by Morley (1976) is odor production. *Mouriri* species often have a strong perfume scent (Buchmann & Buchmann, 1981; Renner, 1984). Perhaps a volatile oil would persist longer when mixed with the fatty oils and other compounds. Buchmann & Buchmann (l.c.) suggested that the glands, which absorb ultraviolet light, might visually guide the bees to the pollen. Extending this idea, one might ascribe a pseudonectary role to the staminal glands. It is interesting that in the Bonnetiaceae, at least 23 species of *Caraipa* and *Mahurea* have very similar minute urceolate glands positioned subapically on the connective (Kubitzki, 1978). The role of these glands, as of those of *Mouriri*, is obscure.

Seed Dispersal in Melastomataceae

Of the neotropical Melastomataceae, 40% have capsular fruits and wind-dispersed seeds (Renner, 1986). The remaining 60% have soft, juicy berries and endozoochorous seeds. Animal-dispersed Melastomataceae are most diverse in lowlands and montane forests, whereas the capsular-fruited tribes are richest in species in various types of savannas. Melastome capsules are often sturdy and persist on the plants for many months, during which the seeds are gradually shaken out. There are no data on dispersal distances in the wind-dispersed species; however, the many striking disjunctions observed in savanna melastomes (Renner, 1987b, and in press) probably attest to their good dispersability. Small herbaceous understory species with broadly conical capsules (*Salpinga*, *Monolena*, *Bertolonia*) may also have their seeds dispersed ballistically by raindrops.

Melastome berries range in size from five to ca. 35 mm in diameter. The smaller ones are of outstanding importance for small frugivorous birds throughout the Neotropics (Huber, 1910; Snow, 1965, 1971, 1981; Ricklefs, 1977; Skutch, 1980; Lumer, 1982; Wheelwright et al., 1984; R. Bierregård, pers. comm., and many additional references). Epiphytic Melastomataceae are mostly bird-dispersed (Renner, 1986), as are many of the most successful pioneer species, for example, *Clidemia hirta*, which has become a noxious weed in Africa, Asia, and Hawaii.

Fruit attributes, such as position, size, aroma, and color, indicate that different animal classes act as the principal dispersers in different species groups. For example, black spider monkeys are the predominant consumers and likely dispersers of the green, slightly astringent and relatively large berries of the tree *Bellucia grossularioides* in Surinam (Roosmalen, pers. comm.). In French Guiana,

this species is a favorite with the *Philander opossum* (Atramentowicz, 1982), which also eats *Henriettea* and *Loreya* fruits. However, a search of recent literature on feeding records (Renner, 1987a) showed that Melastomataceae are not among the preferred foods of either monkeys or bats (for bats, Fleming, 1986; but compare Foresta et al., 1984, and Fleming, 1988). Perhaps because the majority of Melastomataceae are shrubs or understory trees with terminally positioned infructescences, they are unsuited for foraging monkeys and bats. Also, the taste of the mostly sweet, watery melastome berries may not be to the liking of monkeys, which apparently prefer slightly acidic fruits (Sourd & Gautier-Hion, 1986).

Fruits that have fallen to the ground are often eaten by turtles (Moskowitz, pers. comm.; Roosmalen, pers. comm.), lizards (W. Magnusson, pers. comm.), rodents (Magnusson & Sanaiotti, 1987), tapirs (Huber, 1910), and ants (pers. obs.).

Seed Dispersal in Memecylaceae

All Memecylaceae have berries, ranging in size from 0.5 to 10 cm long; color at maturity is most commonly yellow to red, less often it is purple-black to black (Morley, 1976). The smaller-fruited species are surely bird dispersed; some larger-fruited ones are monkey-dispersed (Roosmalen, 1985). Fish eat the fruits of at least one riverine *Mouriri* species (Goulding, 1980), which is curious, since Morley (1976) reported that two other species are used for poisoning fish.

Reproductive Biology and the Evolution of Melastomataceae and Memecylaceae

Floral morphology in Melastomataceae and Memecylaceae can only be understood as the result of coevolution between the earliest ancestors of these groups and pollen-collecting bees. Flowers of the Old World members of both families have the same basic construction as those of their New World relatives and, although little information is available on their floral biology, van der Pijl's (1939) detailed description of the pollination mechanism in some species of *Osbeckia*, *Medinilla*, and *Melastoma* makes it likely that they are pollinated in the same manner as the New World ones. The pollen offered in the poricidal stamens of both families is accessible exclusively to bees, but not to many of the most common ones, such as the numerous species of *Trigona* and the paleotropical *Apis*, which apparently do not vibrate stamens. Most Melastomataceae and Memecylaceae have "modern" pollen flowers in the sense of Vogel (1978), in which the visitor is forced into a fixed position while harvesting the reward and in which the position of the stigma is of relatively little consequence because of the deposition of pollen on a large part of the visitor's surface.

There appears to be little opportunity for partitioning the bee body. Sharing of pollinators, noted rather frequently among sympatric buzz flowers (Linsley & Cazier, 1963; Macior, 1970, 1971; Thorp & Estes, 1975; Lumer, 1982; Renner, 1984), results in hybridization in the absence of genetic barriers. This is consistent with the fact that systematists working with Melastomataceae and Memecylaceae often notice hybrids (Kral & Bostick, 1969; Whiffin, 1973; Morley, 1976; Almeda, 1978; Solt & Wurdack, 1980; Renner, in press). The data on Melastomataceae breeding systems corroborate the suggestion that apomixis may be more widespread in the tropics than formerly thought (Kaur et al., 1978; Ashton, pers. comm., 1987). Apomictic seed production would make such species independent of pollinators, while retaining the advantages of producing seeds, i.e., the potential for dispersal and dormancy. Most notably, it would give them the capacity to build up a new population from a single propagule.

Statements that "details of the structure of the anthers doubtless relate to mechanisms of pollination" (Cronquist, 1981) or "in a family, such as the Melastomataceae, where floral evolution has been extensive, one may logically conclude that the diverse floral types represent adaptations to different pollination systems" (Almeda, 1977) are not corroborated by field data. Rather, Melastomataceae seem to confirm Macior's (1971) suggestion that buzz pollination is so successful a system that, once it is established, hardly any other pollination mechanism evolves, even in species-rich groups. Compared with other families, such as Lecythidaceae, Gesneriaceae, and Bignoniaceae, for which the overall pollination spectrum is fairly well known, Melastomataceae and Memecylaceae show little diversification in floral morphology and pollination strategies. In this they resemble Malpighiaceae (Anderson, 1979) and Solanaceae (Symon, 1979), which also have relatively specialized pollination systems and faithful bee pollinators. Such lack of diversification could be interpreted as the result of being stuck on an adaptive peak.

Melastomataceae that offer nectar are pollinated by a broader range of pollinator classes, namely by hummingbirds, bats, rodents, and bees; this statement applies to the individual species as well, several of which have more than one important pollinator type, for instance birds and bats in *Tibouchina grossa* and bees and rodents in *Blakea chlorantha*. Cruden (1972) suggested, as a possible

ecological significance for nectar production at higher altitudes, that under adverse climatic conditions the homoiothermic birds and mammals may be more reliable pollinators than bees. If valid, this explanation would apply to all now known nectar-producing Melastomataceae, except the species of *Miconia*.

Whether the thousands of pollen-only Melastomataceae derived from ancestors with nectar flowers or whether the proto-Melastomataceae never possessed nectaries (as suggested by Vogel, 1978) is a difficult question. Phylogenetically, the extant nectariferous species belong to groups not closely related: *Meriania* and *Centronia* are in the capsular-fruited Merianieae (as is *Axinaea*, which probably also has some nectariferous species, see above); *Brachyotum* and *Tibouchina* are in the likewise capsular-fruited Tibouchineae; *Chalybea*, *Huilea*, and *Miconia* are in the berry-fruited Miconieae; and *Blakea* is in the also berry-fruited Blakeeae. Thus nectar production occurs in at least five evolutionary lines: the first leading to *Meriania* and *Centronia* (which are not closely related to each other), the second to *Brachyotum* and *Tibouchina* (the first genus is a segregate of the second; Wurdack, 1954), the third to *Chalybea* and *Huilea* (two intimately related genera), the fourth to *Miconia* (with 1,000 species, only two of which to date are securely known to produce nectar), and the fifth to *Blakea*. Nectaries could have originated independently in all these lineages.

The problem is confounded by the slits observed in the filaments of some non-nectariferous Melastomataceae exactly in the same position as in some of the nectariferous species, where nectar is secreted through them. They occur in species of *Heterocentron* (Tibouchineae), *Bertolonia* (Bertolonieae), and *Centradenia* (Microlicieae) and in the paleotropical genera *Medinilla* and *Dissotis* (compare above under nectariferous melastomes) and may be rudimentary, nonfunctional nectaries. Thus, to date, only in two of the neotropical tribes—the small Rhexieae with 64 species and the Cyphostyleae with nine species—are nectar production or presumed rudimentary nectaries absent. In view of the presence of nectaries in at least five neotropical lineages and the indications of their former presence in two further ones, their parallel independent origin becomes hard to accept. Instead, I suggest that the capacity for developing nectaries is basic in the Melastomataceae but suppressed in most modern members.

To understand the origin of the memecyloid connective gland, whatever the chemical composition of its secretion, the following observations seem relevant. Functioning nectaries have been observed on the hypanthia of *Memecylon edule* Roxb. (= *M. ramiflorum* Desr.; Burck, 1891) and *M. floribundum* Blume (Zimmermann, 1932). Also, I have frequently seen ants on the hypanthia of *Mouriri nervosa*, which may be an indication that this neotropical Memecylaceae also secretes sugar, albeit in minute quantities. Evolutionarily, the capacity to secrete minute quantities of exudates directly through the hypanthium epidermis, without conspicuous morphological structures, may be correlated with the development of the staminal glands. However, data on the pollinators and the chemical composition of the exudates of paleotropical Memecylaceae are needed before the significance of the staminal glands in the family as a whole can be assessed. The Memecylaceae have ca. 340 Old World and 89 New World species, and it should be noted that, in the opinion of Morley (1953), the New World Memecylaceae are more basal than the Old World ones.

There is a great amount of parallelism between the Old World and the New World tribes in the Melastomataceae: the Oxysporeae, Sonerileae, Dissochaeteae, and Osbeckieae resemble more or less closely the Merianieae, Bertolonieae, Miconieae, and Tibouchineae, respectively, of the New World (Gleason, 1932). Based on wood anatomy, the differentiation into at least some of these tribes and into Melastomataceae and Memecylaceae occurred before the breakup of Pangaea (Vliet et al., 1981). However, the coevolutionary relationships between bees and proto-Melastomataceae, which are a conditio sine qua non for the evolution of the melastome androecium, can only have begun during the mid-Cretaceous when bees arose (Michener, 1979). The mid-Cretaceous may thus have been the time when the ancestors of these families switched from nectar-reward flowers to pollen-reward flowers (with the pollen presented in poricidal anthers and available only to bees). Likely, the Melastomataceae and Memecylaceae originated during Aptian times (lower mid-Cretaceous, 110 million years before present), when the gap between Brazil and Ghana was still very narrow; their east and west Gondwanian lineages, probably coevolved in parallel with the earliest bees. The oldest fossil melastome leaves are known from the early Eocene (Hickey, 1977), about 53 million years before present, and Eocene and Miocene leaves occur widely scattered throughout the Northern Hemisphere (Wurdack & Kral, 1982). Therefore, members of the family (and some of their pollinators?) at one time may have dispersed via Europe between North America and Africa.

The Melastomataceae, with two-thirds of their species in the Neotropics, have much of their di-
